The United States National Academy of Sciences–National Research Council has set up an Armed Forces–National Research Council Committee on Bio-Astronautics to advise the Armed Forces on matters concerning the biological or medical aspects of space exploration. The following scientists—representing different fields of endeavour in universities, private research organizations, and the Armed Forces—have been appointed to the Executive Council: *Chairman*, Dr. Otto H. Schmitt (Department of Physics, University of Minnesota); *Vice-Chairman*, Dr. Melvin Calvin (Department of Chemistry, University of California, Berkeley); *Members*, Dr. Howard J. Curtis (Department of Biology, Brookhaven National Laboratory), Dr. Paul M. Fitts (Department of Psychology, University of Michigan), Brig.-Gen. Don D. Flickinger (Directorate of Life Sciences, Air Research and Development Command), Dr. John D. French (Department of Anatomy, University of California Medical Center, Los Angeles), Capt. Charles F. Gell (Office of Naval Research), Dr. James D. Hardy (U.S. Naval Air Development Center, Johnsville, Pa.), and Col. Robert H. Holmes (Research and Development Command, Office of the Surgeon General, Department of the Army). Administrative responsibility for the Committee has been vested in the National Research Council's Division of Medical Sciences, under the chairmanship of Dr. R. Keith Cannan. The other members of the Committee are Dr. Sam F. Seeley (secretary) and Major Kay Cutler, of Air Research and Development Command. The full Committee on Bio-Astronautics —which will consist of more than a hundred members, of whom at least half will be nominees of the Armed Forces—will meet periodically to review scientific and technical problems, exchange information, and establish liaison between investigators with allied interests. It will concern itself with any field of science or of technology bearing upon bio-astronautics, including pertinent aspects of astronautics, biology, chemistry, medicine, physiology, psychology, and related interdisciplinary sciences.

The Association of Consulting Scientists

The Association of Consulting Scientists has recently been formed, to act as a clearing bureau for inquiries for independent scientific services. Membership of the Association embraces independent wholetime consulting scientists in the United Kingdom in all fields of science and technology other than medicine and civil, mechanical and electrical engineering. The founding members are mostly chemists and biologists, but physics and other sciences are expected to be represented soon. The new Association will operate in close collaboration with the Royal Institute of Chemistry and other professional institutes, and with organizations concerned with the co-ordination of British efforts in research, production and marketing. The following officers of the Association have been elected: *Chairman*, Dr. J. G. Davis; *Hon. Treasurer*, Dr. G. W. Ferguson; *Hon. Secretary*, W. H. Stevens, to whom inquiries can be addressed at 15 Hawthorne Road, Bromley, Kent.

The Leopoldina German Academy of Sciences: Elections

THE Deutsche Akademie der Naturforscher Leopoldina, Halle, recently elected the following new members, in the sections indicated: *Anatomy*, Prof. Stefan Krompecher (Debrecen, Hungary), Prof. Dietrich Starck (Frankfurt am Main), Prof. Friedrich Wassermann (Lemont, Illinois), Prof. Wolfgang Bargmann (Kiel); *Surgery*, Prof. Willi Felix (Berlin), Prof. Karl Vosschulte (Giessen), Prof. Rudolf Zenker (Munich), Prof. Heinrich Kuntzen (Jena), Prof. Egbert Schwarz (Erfurt); *Zoology*, Prof. Manfred Gersch (Jena); *Mathematics*, Prof. Heinz Hopf (Zurich), Prof. O.-H. Keller (Halle); *History of Science and Medicine*, Prof. Pedro Lain Entralgo (Madrid), Prof. N. A. Figurovskij (Moscow), Prof. P. A. Juschkewitsch (Moscow); *Chemistry*, Prof. Josef Anton Goubeau (Stuttgart); *Botany*, Prof. Bohumil Němec (Prague); *Physiological Chemistry*, Prof. John T. Edsall (Cambridge, Mass.); *Odontology*, Prof. Wilhelm Meyer (Göttingen); *General Biology*, Prof. Eduard Kellenberger (Geneva).

"Some Palæomagnetic Investigations on Chinese Rocks"

DR. A. E. M. NAIRNS has written in connexion with this communication in *Nature* of January 24, p. 254, stating that the present Fig. 1 is incorrect; the plotted points are mirror images of the actual points. On the original tracing, the graduations were drawn on one side of the sheet and the experimental points were, unfortunately, inserted on the other side; in preparing the block, the tracing was photographed from the wrong side.

Announcements

PROF. I. N. SNEDDON, professor of mathematics in the University of Glasgow, has been awarded the Makdougall-Brisbane Prize for 1956–58 of the Royal Society of Edinburgh for his work on thermal stresses published in the *Proceedings* of the Society within the period of the award.

THE Institution of Electrical Engineers is organizing an International Convention on Transistors and Associated Semiconductor Devices, which will be held at Earls Court, London, during May 21–27, together with an exhibition of scientific instruments employing such devices. Further information can be obtained from the Secretary, Institution of Electrical Engineers, Savoy Place, London, W.C.2.

THE second conference on Liquid Fuels, organized by the Institute of Fuel, is to be held at the Palace Hotel, Torquay, during May 11–14, when twenty-one papers will be presented. Enrolment forms are available from the Secretary, Institute of Fuel, 18 Devonshire Street, London, W.1, from whom further information can be obtained.

A JOINT meeting of the British Radio Frequency Spectroscopy Group and the Groupement AMPERE will be held in the Physics Department, Queen Mary College (University of London), Mile End Road, London, E.1, during April 1–3 on "The Study of Molecular and Atomic Motions in Solids and Liquids by Radiofrequency Methods". Further information can be obtained from Dr. J. G. Powles at the address given above.

THE Conference of the Oil and Colour Chemists' Association will be held in Edinburgh during May 5–9. The technical sessions, under the general title "A Survey of Polymers", will be held in the North British Hotel under the chairmanship of Prof. E. L. Hirst. Registration forms and further information can be obtained from the general secretary, R. H. Hamblin, Oil and Colour Chemists' Association, Memorial Hall, Farringdon Street, Holborn, London, E.C.4.

A CONFERENCE on Industrial Prospects in Nuclear Energy is being organized by the European Nuclear Energy Agency of the Organization for European Economic Co-operation. The conference, sponsored by the industrial federations of member and associated countries, and by the Council of European Industrial Federations, is to be held in Stresa, Italy, during May 11–14. Further information can be obtained from the European Nuclear Energy Agency, 38 Boulevard Suchet, Paris 16e.

A JOINT meeting of the AGARD Aeromedical and Flight Test Techniques and Instrumentation Panels will be held in Athens during May 11–15. The subject of survival and the reactions of the pilot to unforeseen hazards will be discussed. Special papers will be presented on: escape and survival techniques; medical and human engineering aspects of flight in non-conventional aircraft; and psychopathological stress problems in flying personnel, considered exclusively with reference to research required, or data obtained from research already carried out. Further information can be obtained from the Advisory Group for Aeronautical Research and Development, Organisation du Traité de l'Atlantique Nord, Palais de Chaillot, Paris 16°.

A JOINT symposium on Instrumentation and Computation in Process Development and Plant Design, organized by the Institution of Chemical Engineers, the Society of Instrument Technology and the British Computer Society under the ægis of the British Conference on Automation and Computation, is to be held at the Central Hall, Westminster, during May 11–13. Sessions will be devoted to improving the efficiency of existing processes; the design of new processes; the application of on-line computers; recent developments in instruments, on-line computers and computers for design; and the use of computer techniques in large and small companies. Preprints of the proceedings will be available; attendance is open to members of the sponsoring bodies and non-members on payment of a registration fee. Further details can be obtained from the General Secretary, Institution of Chemical Engineers, 16 Belgrave Square, London, S.W.1.

NEW CANADIAN FIRE RESEARCH LABORATORY

By R. F. LEGGET

Director, Division of Building Research, National Research Council of Canada

FIRE research in Canada advanced significantly with the opening on October 3 of the new Fire Research Laboratory of the National Research Council of Canada at Ottawa. The new building forms part of the Building Research Centre of the Council's Division of Building Research. It is situated on the extensive property of the Council known as the Montreal Road Laboratories, an area of about 400 acres in which the three engineering research divisions of the National Research Council and some other Council establishments are situated.

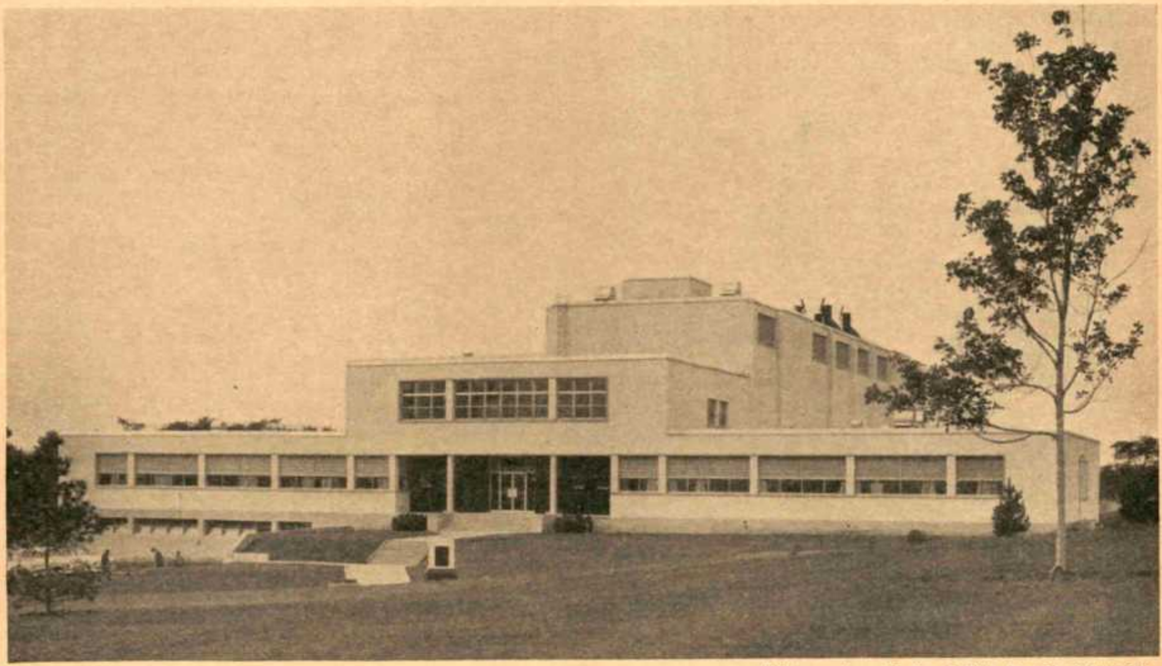
The official opening of the building was performed by Dr. F. M. Lea, director of the British Building Research Station, assisted by Mr. Dennis Lawson, the newly appointed director of the British Joint Fire Research Organization, both of whom had come to Ottawa especially for the occasion. The Canadian Division of Building Research has close liaison with both these British research organizations, the debt to which in the development of its work and in the planning of the new building was acknowledged by the director during the opening ceremony.

The opening of the new building followed a two-day conference on fire research and fire prevention, at which statements were presented regarding the work of all the major fire-prevention agencies of Canada. Speakers from the United States, Britain and Canada gave a review of fire research throughout the world. Some details of Canadian fire research were given to the conference, including preliminary results from full-scale burns of eight buildings in the small town of Aultsville, abandoned because of flooding caused by the construction of the international power dam on the St. Lawrence.

The fire research building (Fig. 1) has basically the shape of a large T, with offices and laboratories in the front wing, and the large furnace laboratory and a burn area for model studies in the rear wing. One-story additions have been erected on either side of the furnace laboratory to provide storage and workshop facilities, garage space for the station wagon used in field investigations, a control room for the operation of the fire-resistance furnaces, and additional laboratory facilities for hydraulic testing.

The building covers an area of 20,000 sq. ft. and has a total volume of more than 550,000 cu. ft., of which nearly half is made up of the volume of the 40-ft. high structure housing the furnace laboratory and the burn area. The total contract price, including all extras, which amounted to less than 4 per cent of the original cost, was 820,000 dollars, or a cost per cubic foot of less than 1.50 dollars.

The building, founded throughout on solid rock, consists of a structural steel frame supported on reinforced concrete. The outside walls, built of structural clay tile, are finished with stucco on metal lath on the outside and with glazed tile on the inside.



(*Photograph: National Film Board of Canada*)

Fig. 1. Fire Research Building of the Division of Building Research, National Research Council, Ottawa

The area to the rear of the Fire Research Building was the site of an old quarry. Its rocky floor, which is approximately 5–10 ft. below the level of the surrounding area, provides an excellent outdoor experimental site on which to conduct large-scale tests on extinguishing fires.

The fire-resistance test facilities consist of two furnaces, complete with auxiliary equipment, together with the associated facilities for constructing, handling, conditioning and disposing of large test specimens. The design of the special facilities contained in the laboratory was carried out concurrently with the design and construction of the building itself, by a separate firm of consultants, Ewbank and Partners (Canada), Ltd., working in co-operation with the architects and engineers for the building.

The wall furnace (Fig. 2) consists essentially of a movable burner assembly open at the front, with the burners situated in the rear wall of the unit. The combustion chamber is completed when the front face of the burner assembly is fixed to the specimen under test. In this position the top of the furnace is immediately under the flue used for removing the combustion gases.

The size of the specimen exposed to the combustion chamber is 12 ft. by 12 ft., although the loading frame itself will accommodate a specimen 14 ft. by 14 ft. The heat in the combustion chamber is supplied by 100 burners having a capacity of 50 cu. ft. of gas per hour at a pressure of 25 lb./in.^{2}. The fuel used is propane, having a gross heating value of approximately 2,500 B.T.U./cu. ft.; thus the maximum total heat input is approximately 12,500,000 B.T.U./hr.

The floor furnace (Fig. 3), in contrast to the wall furnace, is a fixed installation. The burners are installed in the two long sides and the two flues are permanently connected to the common flue used for conducting the flue gases from the building. The combustion chamber is completed when the specimen is laid on top of the furnace.

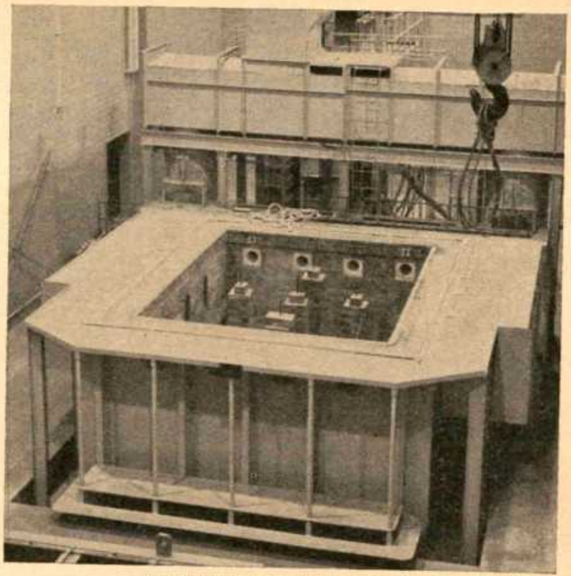
Fig. 2. Loading frame with wall specimen in wall furnace in the furnace laboratory



(*Photograph: National Film Board of Canada*)

Fig. 3. Floor furnace in the furnace laboratory

The furnace at present will allow a floor specimen to have an area of 12 ft. by 15 ft. exposed to heat. When using this furnace for testing beams it will be possible to extend a beam past the furnace wall and load this portion of the beam as well.

Heat is supplied by means of thirty burners (fifteen on each side), each burner having a capacity of 220 cu. ft. of gas per hour at a pressure of 25 lb./in.^{2}. As in the case of the wall furnace, propane will be the fuel, so that the gross heat input is approximately 16,500,000 B.T.U./hr.

Liquid propane is stored in a 1,750-gallon tank situated outside the building. When operating the furnaces, the liquid is passed through three vaporizers, each capable of vaporizing 70 gallons of propane per hour at 25 lb./in.^{2}. The gas is then piped underground in a 4-in. pipe to the building. Inside the building the propane then passes through a diaphragm motor control valve, which closes if there is a failure of the control air. There is a pilot flame by-pass valve in the line before the motor control valve, and two shut-off gas cocks immediately after this valve direct the flow either to the floor or to the wall furnace. The wall furnace has ten banks of burners with ten burners in each bank, while the floor furnace has five banks of three burners each on each side. Each group of three burners is fitted with a solenoid-actuated shut-off valve and pressure gauge.

The combustion control for both of the furnaces is furnished by a potentiometric temperature-programme controller which follows the time – temperature curve designated in the current U.S. Standard (ASTM *E*119-57, Standard Methods of Fire Tests of Building Construction and Materials).

The two large furnaces will be put to use immediately for carrying out tests upon the fire-resistance of building materials in current use in Canada. These tests must be done since the furnaces are unique in Canada, but they involve an element of research, and the furnaces will be used for research investigations whenever possible. In the laboratories, studies will continue on the properties of foam as an extinguisher of fire, into the problems of radiation from fire and on more detailed questions such as those related to the burning characteristics of materials. The results of all work will be made available to the committees responsible for the National Building Code of Canada for incorporation into successive revisions. The Code is an advisory document published by the National Research Council of Canada, and has legal effect only when adopted by municipalities for their own local use. It is already in legal use in this way for well over one-third of the population of Canada. As its adoption spreads, the results of the fire research programme will therefore be of direct effect to a large proportion of the people of the Dominion.

CHANGING INDUSTRY

THERE are clear signs that the post-war period of steady expansion is coming to an end. European competition is increasing, and there is a formidable growth of productive capacity in every continent. Apparent over-capacity in industry, the coming of nuclear power, international shortage of capital and low raw material prices are all contributing to a readjustment of the world's economy and are posing a direct challenge to British management.

This was the theme of the national conference of the British Institute of Management which was held at Brighton during November 26–28, 1958. The variety of papers presented by many distinguished speakers gave the hundreds of delegates considerable choice of meetings to attend; this is one of the admirable features of the Institute's conference which commends it to so many members but also makes it impossible to describe adequately. In two days there were twenty-three separate meetings and at least twenty-five study groups at which the topics ranged from staff assessment and grading to the best use of scientists in industry, the balance between technological education and management education and the problems of accounting in large multi-unit undertakings.

In the opening address Sir Harold Howitt, one of the three members of the Council on Prices, Productivity and Incomes, emphasized that the chief challenge facing management is inflation. So-called creeping inflation with its cumulative effects may soon become galloping inflation and get out of hand. But it is no use paying lip service to the desirability of killing inflation unless one is prepared to take the medicine that is involved in the process. Nor is it any use putting all the blame for inflation on one or other section of the community or expecting it to take all the medicine. All must exercise restraint. Wage increases are not harmful if they keep within the increase in productivity, since prices can then remain stable and the increase in wages will have been real. In the industrial field as a whole, total profits after depreciation from 1950 to 1956 have been about one-third as much as wages and salaries; profits must bear their share of responsibility for inflation.

One of the most important contributions to the conference was made by Griffith Page, managing director of the National Union of Manufacturers Advisory Service, Ltd., who described the ways in which small firms were being helped towards greater efficiency. Five years ago the Union was set up as a department of the National Union of Manufacturers, with financial aid under the Conditional Aid Scheme, and with emphasis on management and production organization. The lines along which the service developed were decided by the nature of the problems presented by the firms who sought its aid, by conviction that efforts and resources should be directed towards making the maximum possible impact in terms of productivity and efficiency upon the general population of small firms, and by the necessity to make the service self-supporting.

The natural interest of the membership of the National Union of Manufacturers and occasional Press reports have been adequate to generate a flow of inquiries, the follow-up of which has kept a growing staff fully engaged.

Altogether, some five hundred firms, representative of a wide cross-section of the smaller firms, have used the service, and the Union's Advisory Service has been able to acquire an increasingly intimate understanding of the financial pattern, the management structure, the production organization and the problems of small firms. Although the promotion of work study as a principal agency for promoting higher productivity held, and does still hold, an important place among the objectives of the Advisory Service, it was necessary to take a wider view of the management problems in small firms. This led to the adoption of a survey technique which approximates to the American concept of the management audit. Such surveys involve an appraisal of the overall business position of a company, its industrial standing, its policy and objectives, financial position, management structure, sales organization and productive efficiency. Their purpose is to enable the National Union of Manufacturers Advisory Service, Ltd., to indicate in what directions companies can most beneficially take action to improve their prosperity and well-being.

After such a survey, recommendations are made, and these may cover any one or a number of areas of management responsibility. The firm may be advised to install one or other of the principal management techniques, of which work study is predominant, because it usually provides the necessary foundation for others, like production control and standard costing. The introduction of work study is one which requires an appreciable period of full-time assistance, and the Advisory Service staff of industrial engineers is available to shoulder the main responsibility for its introduction and to train members of the firm's own staff so that the schemes introduced shall be properly maintained. The Advisory Service seeks to assess the limitations and the potentialities of the smaller firms in the total business sense, to explain how sound principles of management and modern techniques of management can be applied in the context of their own highly individual situations, to indicate the advantages which can flow from their adoption and, in so far as it is necessary to ensure that this is adequately accomplished, by helping them either on a part-time or full-time basis over a period.

In a thoughtful and stimulating paper concerned with the challenge of change in export markets, Mr. B. H. Dyson, sometime director and general manager of Hoover Overseas Production, Ltd., emphasized that, although many people think that Britain's troubles stem from trade unions, shop stewards, restrictive practices, cradle-to-grave social services, or nationalized industries, the restrictive outlook and practices of management could be more dangerous. The most dangerous factor in Britain to-day is acceptance of the lowering of the standard of expectancy. How can one expect a higher standard of living and yet apply less physical, mental and spiritual effort towards its attainment ? The challenge of the change calls us to create the attitude of mind conducive to arousing the desire of achievement. One factor which can actively contribute to the conversion of high wages into low costs and competitively priced products into a higher standard of living is the continuous and progressive rise in both management and worker productivity. Future success will depend almost entirely on directors and management having the courage to accept change ; products of superior styling and design ; manufacturing at competitive costs, consistent quality and realistic delivery ; good salesmanship and adequate service.

To-day with many directors and managers the home market takes precedence over export markets simply because the home market is familiar to them and its requirements fully understood. With export markets the profit margins are smaller, adding further to the temptation to rely on the more assured and less exacting demands of the home market. Only too frequently a company will take infinite trouble to appoint a representative to look after the Birmingham market, but will be content to appoint an agent (without even having seen him) to look after a whole country abroad.

The only way to explore the possibilities of business overseas is by personal visits to gain knowledge of the country itself, of the sort of competition which exists there, of the sales methods which will work most successfully, and of the field covered by other foreign competitors as well as by the nationals.

If the extent of the business potential does not warrant setting up an overseas company, the appointed representative should know details of the company's expectations, prices, terms of payment, stocks, service, advertising samples, methods of handling competitive merchandise, commission, profits, deliveries, expenses, literature and price lists.

Not enough training is being given for the export market. Not enough engineers from the countries now developing towards an individual economy are being offered postgraduate training with British engineering firms, while British sales and technical engineers going overseas for their companies are not being given the necessary additional training in the customs and language of the overseas countries to enable them to present British industry at its best.

Often in overseas markets a typical British design is not acceptable, and the overseas customer cannot always be sold the idea that the British home market is the acme of good design. Full-sized British egg-cups are not suitable for the small-size Indian and Asiatic egg, and lawn mowers built for the trim lawns of Britain are useless for Australia, New Zealand and uneven coarse grass. In India it is said that British motor-cars are recognized by a 2-in width of adhesive placed around the edges of the windows to keep out the monsoon rains. Style and colour are selling features, and here the product must be a fashion leader and not a fashion follower.

The design office and drawing-board are the cradle and kindergarten of production costs. If the design of the product and each individual component is not efficient from a functional or accepted standard point of view, no matter how perfect the manufacturing may be, the cost of production will be high. A factory in France is manufacturing 17,000 coffee mills a day that are sold all over the world at between 30*s*. and £2 each, and no competitor has been able to approach the value. A manufacturer of electric frying pans tooled up for 3,000 per week and has not been able to maintain 300 per week, because good as the value may be, the average housewife regards a frying pan as a 10*s*. 6*d*. article. An article which sells well at 1*s*. may not sell in a larger size at 1*s*. 6*d*. even if better value is represented by the larger size.

Research into the problem of designing for low-cost production is an important step towards enhancing sales. The main object should be to direct research into : (1) the reduction of the number of component parts ; (2) the reduction in the number of production operations ; (3) minimizing metal removal operations and the standardization of detail.

Efficient utilization of material demands a change of outlook on manufacturing costs. Often considerable time, ingenuity and expense are involved in designing and making machines and tooling aimed at reducing the direct labour cost by 10 per cent. A 10 per cent saving on direct material would show a much greater cost saving. Investigations into this aspect of cost reduction have indicated that often one must consider not only the value of the material in the product, but also the ratio of material utilization to the original material purchased. The design specification can assist production by : (1) reducing to a minimum the variety of finishes ; (2) standardizing chemical or plated finishes that assist the economics of mechanizing the finishing processes ; (3) commoning-up and standardizing on the undercoats for enamel finishes ; (4) arranging that the variety of finish coats can be baked at a consistent time and temperature so as to aid the mechanization of dip, spray, electrostatic and baking operations to a conveyorized process.

Considerable attention must also be given to ensure consistent quality standards from machining operations. Often the production engineer neglects to define in the process operation sheet the inspection operations, stating in detail the dimensions and points which need to be checked. To 'motion study' a production operation and ignore the workplace and equipment supplied to inspection viewers is paying lip service to the important job of maintaining consistent quality at controlled prices.

Nothing is more disappointing to a customer than transit damage, whether it be frost-bitten fruit trees, scratched furniture, a chipped surface plate or an out-of-line machine tool. Correct packing is essential and can be costly. Special containers and crates to assist transportation may be necessary. Shipping space and conditions have to be considered ; under the water-line stowage may need extra protection.

In the American and Canadian market, especially, the styling and presentation value of the package is very important as a sales feature. The product may have a "good old English reputation"; but the pack must be cleverly styled so that the old tradition is presented in conformity with the currently accepted mode.

The method to be used in marketing a product in a specific country is a top-level decision. If the potential market is large enough it is invariably best to establish a subsidiary company. It is certainly more satisfactory to appoint an importing house to act as agent or a company to handle the sole distribution rights than to accept orders from all and sundry.

One of the most unusual management training centres in Europe was described by Clark E. Myers and F. A. Kirby. The school was set up at Lausanne in September 1957 by the Nestlé Alimentana Co., and is designed to provide a nine-months course in business administration for middle management executives from all over the world. The staff consists of American professors recognized in their fields for teaching, publication, consulting and research who wish to continue working in an environment which closely resembles an academic situation.

During the first two years, executives have attended the course from companies in Australia, Belgium, Brazil, Canada, Chile, Cuba, Denmark, Egypt, England, France, Germany, Greece, Holland, Italy, Mexico, Puerto Rico, Malaya, South Africa, Spain, Sweden, Switzerland and the United States. Patterned after the middle-management programme of the Harvard Graduate School of Business Administration, the programme is designed primarily for men whose average age is about thirty-five and who fall within the age range of 30–40.

Based on the Harvard experience, from which background nearly all the professors are drawn, the case method is used almost exclusively. The major exceptions are several weeks of the programme where the elements of accounting and statistics are taught. The policy is based on the belief that experienced men can achieve a greater sense of stimulation, motivation and involvement by dealing with actual business situations.

One-third of the course is devoted to the quantitative data areas of control and finance (which includes such work as statistics, accounting, index numbers, budgeting and data processing); one-third to distribution (including retailing, marketing, sales management and international trade); one-sixth to production, factory management, general management and business policy; and one-sixth to human relations, personnel and labour problems.

The professors teach on three consecutive days either at the beginning or end of the week. The remainder of their time is devoted to writing new teaching materials better suited to an international school. In their employment agreements with the Institut pour l'Etude des Methodes de Direction de l'Enterprise they have agreed to forgo all consulting activities and devote full time to teaching, writing and research for the Institute.

The professors are assisted by research associates. These men have nearly all studied or worked in the United States, and among them have knowledge of nearly every European language. They travel with the professors and assist in research and the writing of new teaching notes and case problems.

Through the development of these materials and cases, the professors gain additional insight into European business affairs, provide better class-room data for the participating executives, assist in publicizing the school and stimulate the interest of European executives in business research and education.

During the first year about two hundred 'pieces of work' were produced. These included new cases, translated cases, technical notes, and a major study of food distribution in seven European countries.

With the increased emphasis on international business, with the coming impact of the Common Market and the free trade area, the directing staff of the Institut pour l'Etude des Methodes de Direction de l'Enterprise believes that such an institution with an international outlook is both desirable and necessary.

Of the many other papers, two of the most outstanding were forecasting and controlling the return on capital involved by J. A. Scott, chief financial executive of Hayeshaw, Ltd., and the effect on quality of administration on technical and commercial efficiency by A. C. Durie, general manager (administration) of Shell-Mex and B.P., Ltd.

TURBIDITY CURRENTS

It was thought for many years that the sediments on the floor of the deep ocean were laid down slowly, the rate of deposition being of the order of millimetres a century. Extensive coring has shown, however, that there are many layers of sand, some with shallow-water fauna, interbedded with the normal deep-water clays and oozes. Turbidity currents, in which a relatively thin layer of sediment-laden water flows rapidly down-slope, have been suggested as a possible mechanism. These currents could deposit such layers of sand in a matter of hours.

When first introduced rather more than twenty-five years ago, the notion of turbidity currents was received sceptically; since then large velocities have been postulated, but it is difficult to imagine their being produced by such contrasts in density on such gentle slopes. Nevertheless, the idea is now generally accepted by marine geologists, or at least it would appear so from the discussion of the subject held at the Royal Astronomical Society on November 28. Dr. G. E. R. Deacon acted as chairman.

The evidence supporting the turbidity-current hypothesis was reviewed by Dr. A. S. Laughton. He pointed out that sediment-laden underflows are well known in lakes, being particularly well documented in the case of Lake Mead. It has been estimated that, of the two million tons of sediment deposited in Lake Mead during 1935–48, an appreciable fraction was deposited by turbidity currents extending along the whole length of the lake. The flows are slow, consistent with the slight contrast in density and the gentle slope, but retain their identity for more than a hundred miles.

The classical case of a turbidity current in the ocean is that produced by the Grand Banks earthquake of 1929 which, by breaking a succession of telegraph cables over a period of 14 hours, provided estimates of the velocities reached. These decreased from almost 30 m./sec. to about 6 m./sec. as the slope decreased from about 1 in 100 to 1 in 1,000. It seems that this rapid and highly turbulent flow traversed some 1,000 km. and had a breadth of some 300 km. For some geologists these are unimaginably high velocities on this scale, but Heezen and Ewing, who suggested the turbidity-current explanation, have much to support their view. Not only were several of the cables later found to be buried so deeply as to be irrecoverable, but two cores which Heezen later obtained in the area both had thick sand layers of shallow water origin overlying the normal deep sea deposits.

Turbidity currents in lakes and in the ocean were linked by the laboratory investigation of Keunen, who produced similar flows on a small scale by the sudden release of fluid mixtures of water, clay and sand. The important result was that a simple hydraulic formula was found to apply, implying that the effect of the overlying fluid could be neglected, as could the acceleration in the flow. Turbidity currents in lakes, ocean and laboratory were not inconsistent with the simplest formula used to describe river flow. Using this formula, Keunen estimated the depth of the Grand Banks turbidity current to vary between 270 m. and 120 m. during its passage.

Dr. R. Stoneley, in discussing the suggestion that the breakages of submarine telegraph cables, following the Grand Banks earthquake of November 18, 1929, occurred through the passage of a turbidity current, remarked that the hypothesis has the merit of being more free from *ad hoc* assumptions than some of the other explanations proposed. The idea deserves further examination from the hydrodynamical point of view. In particular, two aspects have to be considered, namely: (*a*) whether the turbidity current would spread longitudinally too greatly to be effective; (*b*) whether the motion of the current would persist over distances of the order of 1,000 km. without being damped out by viscous forces.

Under (*a*), the longitudinal spread of the mass of water charged with sediment has much in common with the problems of the surge following the breaking of a dam and of the subsidence of a column of water, considered respectively by R. F. Dressler, and by W. G. Penney and C. K. Thornhill. A rough calculation based on the work of these authors suggested that the depth of the current as envisaged by Kuenen would be much too great; the hypothesis would be more workable if the current had a thickness of only a few metres. Question (*b*) depends on the viscous drag of a stream at high Reynolds numbers; the theoretical and experimental work of G. H. Keulegan on arrested saline wedges suggests a much lower drag coefficient than is appropriate for lower speeds. Keulegan's experiments show that the logarithm of the drag coefficient depends linearly on the logarithm of the Reynolds number, and an extrapolation of this result indicates a thinner turbidity current, with a vertical thickness of about 5 metres. Such a thickness would help to meet the difficulty mentioned under (*a*).

Further investigations of these hydrodynamical problems are very desirable, and examination is needed of the effectiveness of such a current in transporting and sorting sediments to the degree required.

Two points relating to Dr. Stoneley's contribution were made in the subsequent discussion. It was pointed out that in laboratory experiments the down-slope turbulent flow of a fluid under a less dense fluid leads to the formation of a somewhat bulbous 'nose' which travels only a little slower than the body of the fluid. The speed of the 'nose' is considerably less than the long-wave velocity in a perfect fluid. An adequate theory is not yet available. It was also remarked that the diminution of the drag of the sea-bed with increasing Reynolds number may be unjustified if the bottom is hydrodynamically rough. Observations show no decrease of drag coefficient with increasing velocity in the high Reynolds numbers (greater than 10^7) of tidal streams.

Dr. T. H. Ellison based his contribution on the work he is doing in collaboration with Dr. J. S. Turner. Their investigation concerns the ventilation of coal mines, but is applicable to the many situations in Nature in which a thin layer of turbulent fluid flows between a boundary and a relatively quiescent underlying or overlying fluid of different density. These include katabatic winds in the atmosphere and what appear to be katabatic bottom-currents in the ocean, as well as the many complicated phenomena observed in estuaries. Turbidity currents are a special case in which the turbulent fluid is made heavier by suspended solids. Some dust storms in the atmosphere are probably similar phenomena.

In the case of turbidity currents it seems that a relatively simple hydraulic theory would describe the observations if the friction and mixing with the overlying fluid could be neglected. It is therefore necessary to make some estimate of the amount of the non-turbulent fluid which would be entrained into the gradually thickening layer of turbulent fluid flowing beneath it. The rate of flow into the lower layer can be expressed as EV, where V is a typical velocity of the lower layer. E is the so-called 'entrainment constant', and if the two layers had the same density, $E \simeq 0{\cdot}08$. In this case the interaction of the two fluids could by no means be neglected. However, E decreases as the hydrostatic stability increases and it is reasonable to assume that E is a function only of the Richardson number, Ri, which is a dimensionless measure of the stability given in this case by $Ri \equiv (\rho - \rho_0)\, gh/\rho V^2$, where g is the acceleration of gravity, ρ, ρ_0 are the densities of the lower and upper fluids, and h is the depth of the lower fluid. Two sets of experiments have been made to determine E in relation to Ri. The results are scattered but agree that for $Ri > 0{\cdot}8$, which is the case in turbidity currents, then E becomes very small. The interaction between the two fluids is much reduced by the strong hydrostatic stability, and it is for this reason that a turbidity current can retain its identity for a long period and that the flow can be described by a simple formula applicable to river flow. Ellison's results are therefore broadly similar to those based on Keunen's work and support his conclusion: turbidity currents are compatible with our present knowledge of turbulence in stratified fluids.

The discussion which followed showed almost complete acceptance of this point of view; those against the turbidity-current hypothesis were either absent or silent. This is not to say that no problems remain. We know little of the ways in which turbidity currents are started or of the factors which determine whether water laden with sediment will behave as a heavy fluid or as a sloppy sort of solid. How often do turbidity currents happen? Were they stronger and more frequent during Ice Ages, and could they then have cut submarine canyons?

They presumably happen so infrequently that they make no contribution to the economy of the bottom water. For the same reason there is little hope of direct observation, although bathyscaphists report that they have started mudslides when landing on steep slopes. Attempts to start them by using explosives in canyons have had little success. Altogether, considering its potential importance in the formation of abyssal plains and the structure of some sedimentary rocks, the turbidity-currents hypothesis seems to have had little influence on marine geologists. It is surprising, for example, that following the classical Grand Banks turbidity current only two cores have been collected from the area—and they apparently during borrowed time from a cruise with other objectives. Both these cores, taken some 20 km. apart, have sand layers at the surface. Below this, each has further layers of sand, but there is so little correlation between them that one can only speculate as to the horizontal structure. Taking closely spaced cores is technically difficult, time-consuming and expensive, but in some areas the expense would surely be justified.

H. CHARNOCK

THE BRITISH COUNCIL

REPORT FOR 1957–58

THE annual report of the British Council for 1957–58* includes a general survey of the year and is preceded by an article on the printed word by Sir Charles Snow, which stresses the importance of the work the Council is doing in this field on an expenditure of only £17,000, but urges the need for expansion. The report is accompanied by a separate account of the Council's work for visitors and students from overseas. More than half the report is occupied by appendixes listing the officers, executive committee, advisory committees and panels, with their membership, and giving particulars of university interchanges, courses and study tours, etc., arranged by the Council in the United Kingdom or overseas, exhibitions and publications, and an analysis of the estimates and accounts.

The increase in the Government grant for 1957–58 to £3,378,271 out of gross expenditure of £3,867,899 enabled the Council to start improving the supply of English teachers and teaching material for overseas and other work in accordance with Government decisions contained in the White Paper on Overseas Information Services. Further activities will be possible in 1958–59 with the increase of nearly £650,000 on the original estimates for 1957–58. For this year the Council is recruiting, or helping to recruit, on improved terms, for about seventy overseas teaching posts in English in schools, training colleges and universities, chiefly in Asian countries. It is also co-operating closely with a unit established by the Ministry of Education to assist in placing satisfactorily the returning teacher. Much is being done abroad to help overseas teachers of English, and the Council has also been closely associated with the new School of Applied Linguistics in the University of Edinburgh, to which one of its most experienced English-teaching specialists is being seconded. The Council is contributing £5,000 towards the establishment of an Overseas Visual Aids Centre to further increased and more efficient use of visual and audio-visual aids in formal and informal education overseas.

The specialist tours arranged by the Council include an advisory unit at the request of the Burmese Government of Prof. H. F. Humphreys and Mr. W. J. Deacon to examine and report on the state of education in Burma, a visit to Turkey of thirteen British surgeons, headed by Sir Clement Price Thomas, and tours of Prof. C. Wells to Pakistan, Burma, Thailand, the Philippines, Australia and Canada, to advise on surgical techniques and radiological services, and of Sir Alister Hardy to Pakistan, Thailand, Hong Kong and Japan to inspect oceanographic institutions. More than 1,800 visits of scientific specialists to and from Britain were assisted by the Council in one way or another in 1957–58, representing 35 per cent of the total for all subjects and professions. In numbers this represents 42·6 per cent out of 4,902 visitors to the United Kingdom under the auspices of the Council, compared with 18·5 per cent in social studies, 14·8 per cent in education and 10·1 per cent in medicine; for 1951, the corresponding figures were 23·5, 15, 14·5 and 10 per cent, respectively. There has been a striking growth in recent years of the Council's responsibilities as agents for the United Nations Specialized Agencies, the Colombo Plan, the Baghdad Pact and other international agencies offering training in the United Kingdom, and in 1957–58 1,012 such visitors were cared for in the United Kingdom by the Council, compared with 191 in 1950–51. About £380,000 a year is administered by the Council for international and overseas organizations.

The fifteen short specialist courses arranged annually included one on the economic problems of developing countries, for senior officials and administrators, and in 1957 study tours were arranged for 67 groups, many from British Colonial territories, while in the autumn of 1957, 300 Soviet students and young people were invited to visit the United Kingdom for periods of three weeks. This programme has made considerable progress on an exchange basis with the co-operation of leading student and youth organizations in the United Kingdom, while the Council has also placed a number of postgraduate Soviet scholars in British universities and promoted exchange visits of teachers of English and Russian to summer schools in the United Kingdom and the U.S.S.R.

The number of overseas students in the United Kingdom rose in 1957 to 35,000 and is now about 38,000, less than a third of whom are at universities. In 1957, 7,782 students were met on arrival, 4,644 were assisted to find permanent accommodation, 386 becoming permanent residents in the Council's own residences, which also provided transit accommodation for 1,692 students. New premises were acquired during 1957–58 in Hull, Leeds, Liverpool and Nottingham. Some 13,259 overseas students attended British Council vacation and week-end courses and study visits, and private hospitality was arranged for 5,481 students. Travel grants to university teachers on study leave and to postgraduate workers totalled thirty-six (twelve from Australia) for visits to the United Kingdom and four for visits from the United Kingdom, and under the younger research workers interchange scheme twelve visited the United Kingdom and twenty-five from the United Kingdom visited six European countries.

COSMOGENIC NOBLE GASES IN THE WASHINGTON COUNTY METEORITE

By OLIVER A. SCHAEFFER and DAVID E. FISHER
Brookhaven National Laboratory, Upton, Long Island, New York

AN iron meteorite, designated the Washington County or Arickaree meteorite, was discovered in a Colorado wheat field in 1927. Eugene King, the finder, seemed to observe evidence of heat in the soil in which it was embedded, and as in addition almost no evidence of rusting is observed, it would appear that the meteorite fell recently. A proposed date of fall is 1916[1]. It contains 9·3 per cent nickel[1] and does not show a Widmanstätten pattern; it is thus classified as a nickel-rich ataxite. In this experiment, pieces of the meteorite, supplied to us by the Harvard Museum through the courtesy of Dr. E. L. Fireman, of the Smithsonian Astrophysical Laboratory of the Harvard Observatory, were examined by mass spectroscopy to determine if noble gases, originating from spallation effects induced by cosmic rays, were present.

There has been discussion as to whether the Washington County meteorite is indeed a meteorite, or whether it might be an example of terrestrial iron. The overall appearance of the slab as found was similar to what might be expected of machined iron, as if it might have been discarded from a cast. In addition, voids were observed distributed throughout the mass, in contrast to other known meteorites. The presence of helium-3 was discovered in the present experiment, thus establishing definitely that the metal was exposed to extra-terrestrial cosmic radiation, and is, in fact, a meteorite.

Samples weighing 0·1–0·2 gm. were melted in a graphite crucible at a temperature of approximately 2,000° C. by means of an induction heater. The entire gas line leading from the sample to the mass spectrometer, including the samples of standard gas, were maintained in vacuum at pressures not above 10^{-6} mm. of mercury. The line was constructed of 'Pyrex' glass, formula 1720, which effectively inhibits the diffusion of helium through the walls.

After melting, the escaped gases were purified by passing them over copper oxide and calcium heated to 600° C. They were then introduced into the mass spectrometer and the helium-3, helium-4, argon-36 and argon-38 were quantitatively determined. The argon was then adsorbed on charcoal at liquid-nitrogen temperatures, and the neon isotopes 20, 21 and 22 were measured. Standard amounts of the above gases were added to the sample in the mass spectrometer and the equipment was thus calibrated. Blank determinations were run at the specified crucible temperature before each sample. A blank was run after each sample at a crucible temperature approximately 50° higher. This blank was found to contain approximately 3–5 per cent of the noble gases, indicating that each sample was well outgassed. This amount was then added to the results originally obtained.

It is expected that the results obtained for all isotopes except neon-20 are good to within 10 per cent. The value for neon-20 could not be determined so accurately because of background due to doubly charged argon-40, and it is felt that the true value may vary from that given by up to a factor of 2. No number is reported for the abundance of argon-40 in the meteorite because of this large background of atmospheric argon. The correction that was applied to the argon-36, however, was only 10–20 per cent of the peak value, and that applied to argon-38 was less than 5 per cent. The accuracy of the mass spectrometer was tested by bombarding a gold target with α-particles in the Brookhaven cyclotron, the incident intensity being measured with a Faraday cup[2]. The target was melted in the mass spectrometer and the helium-4 was measured. The results agreed with those measured by the Faraday cup to within 5 per cent. The measured results are shown in Table 1.

Table 1

	Abundance in units of 10^{-8} c.c./gm.						
Sample No.	He-3	He-4	Ne-20	Ne-21	Ne-22	Ar-36	Ar-38
	193	2,700	8	2·14	2·6	5·6	7·8
II	193	3,100	5	1·98	2·2	5·1	7·2
Average	193	2,900	7	2·06	2·4	5·4	7·5

A comparison with other meteorite data can most profitably be made on the basis of rare-gas ratios reported for iron meteorites with high (of the order of 10^{-6} c.c./gm.) helium-3 contents. For example, for the ratio helium-3/neon-21, values are reported ranging from 72 to 130. Our value is 94, in the range of these previous numbers. For the ratio helium-3/argon-38, values are reported[3,4] in the interval 15–40. Our value is 26.

The ratio helium-4/helium-3, however, is approximately five times that previously found for comparable meteorites.

The early experimenters on noble gases in meteorites attributed the helium-4 content to uranium and thorium disintegrations[5], and, on the basis of measured helium-4 and uranium–thorium contents, they determined ages for the meteorites. No general consistency was found in the ages determined for various meteorites by this method. Since these early experiments, two objections to the technique have been raised. From measured amounts of other noble gases in meteorites[6], it is now thought that practically all the helium-4 is, in fact, due to spallation effects from nuclear reactions induced in the meteorite by high-energy cosmic rays[7]. The other objection, raised by Urey[8], is that the dates may be in error due to the diffusion of radiogenic helium along crystal structure boundaries, an argument being advanced that the majority of the uranium will segregate itself along these boundaries. Reed and Turkevich[9] have measured the uranium content of two iron meteorites by neutron activation and have set an upper limit of 10^{-10} gm./gm.—an amount insufficient to account for the helium-4 actually found in meteorites.

In the present experiment the high value for the ratio helium-4/helium-3 may indicate that a considerable portion of the helium-4 is in this case radiogenic. It would thus be possible to estimate the cosmogenic helium-4 content by the measured helium-3 content and the known value of this ratio in other iron meteorites. We have assumed a helium-3/helium-4 ratio of 0·25, natural abundance of uranium-235 and uranium-238 in the meteorite, a thorium-232/uranium-238 ratio of 4, and an age of 10 × 10^9 years[10], and have thus estimated the uranium-238 content of this meteorite to be 3 × 10^{-10} gm./gm. An age of 5 × 10^9 years changes this estimate to 1 × 10^{-8} gm./gm. These values are well within the sensitivity of the neutron activation method of analysis[11] and show a significant variation at the two estimated ages. Accordingly, an attempt will be made in this laboratory to measure the uranium content by this method and possibly obtain a helium–uranium date for the meteorite. The grain boundaries along which the helium might leak out are absent to a large extent in the ataxite structure, and this objection should be greatly reduced.

The argon-36/argon-38 ratio has been measured in other iron meteorites[3,4] and usually found to be 1·6. The value found here for the Washington County meteorite is 1·4. This may be due to the high nickel content, spallation reactions from the predominant nickel-58 isotope perhaps favouring the formation of argon-36; on the other hand, the difference between these values may not be significant.

We wish to express our appreciation for the technical assistance of Mr. J. Densieki and for several valuable discussions with Dr. E. L. Fireman.

This research was carried out under the auspices of the U.S. Atomic Energy Commission.

ABSORPTION SPECTRUM AND DECAY KINETICS OF THE METASTABLE STATE OF CHLOROPHYLL *b*

By PROF. STIG CLAESSON, LARS LINDQVIST and BERTIL HOLMSTRÖM
Institute of Physical Chemistry, University of Uppsala

As part of an extensive investigation of the photochemistry of chlorophyll we have studied the absorption spectrum and decay scheme of the metastable state of chlorophyll *b* in benzene solutions free from oxygen. As some related work in this field has recently been reported[1,2], a short presentation of some of our results may be of interest.

Using the flash photolysis and flash spectroscopy technique[3], the absorption spectrum of the metastable state was determined from 290 up to 840 mμ from measurements during the exciting flash. The red or blue part of the emission spectrum from the flash lamp was isolated for excitation. With the high-energy flash (that is, 400 μF. at 5 kV., and a 60 μsec. duration) at our disposal[4], it was possible to achieve complete conversion to the metastable state. The total absence of chlorophyll *b* in the ground-state increased the accuracy of the absorption spectrum measurements, especially in the region of the absorption peaks of the ground-state.

The optical arrangement was such that no detectable stray light from the exciting flash entered the recording system. Each photographic plate was individually calibrated by a set of seven grey filters.

The concentration of chlorophyll *b* in the benzene solutions was 0·35 × 10^{-6} *M*, and the length of the optical path was 60 cm. At such a length the absorption of oxygen-containing benzene is appreciable up to 350 mμ, therefore the solvent for the blank spectra had to be carefully degassed.

Fig. 1 indicates the absorption spectrum of the metastable state, as obtained from three independent sets of experiments. The ultra-violet region was obtained from a series of 3 plates, 7 spectra; the visible region from 8 plates, 14 spectra; and the infra-red region from 5 plates, 7 spectra. As is seen, the absorption curves from these three wave-length regions tie together in a very satisfactory manner without any corrections. The points obtained from the flash experiments, corresponding to the ground-state of

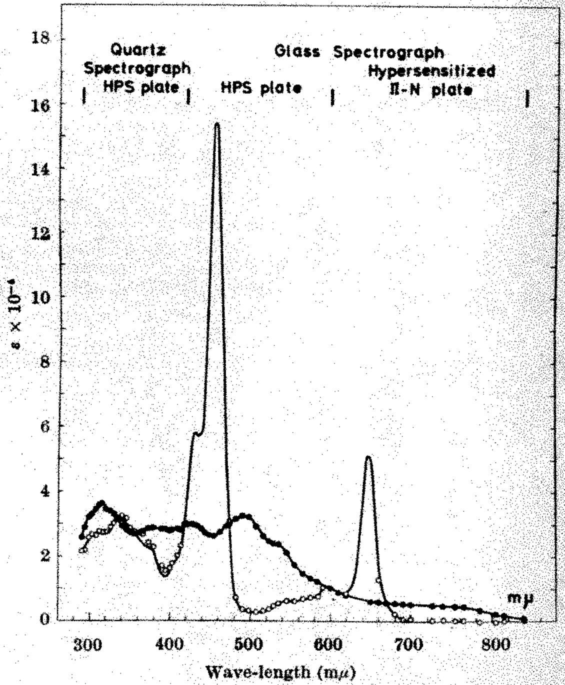

Fig. 1. The absorption spectra of chlorophyll *b* in benzene in its ground-state (○) and in its metastable state (●). The points were obtained photographically from flash experiments, while the solid curve for the ground-state was determined spectrophotometrically. The types of plates used for the different wave-length regions are indicated

chlorophyll *b*, fit very closely to the absorption curve as determined by standard spectrophotometry. These points were corrected for an excitation of 5 per cent caused by the spectrograph flash lamp, this having been established in separate experiments.

The spectrum in Fig. 1 was obtained using only red light for the excitation of the chlorophyll *b*, yet some spectra were also recorded using blue light. The absorption spectra obtained in each case were identical.

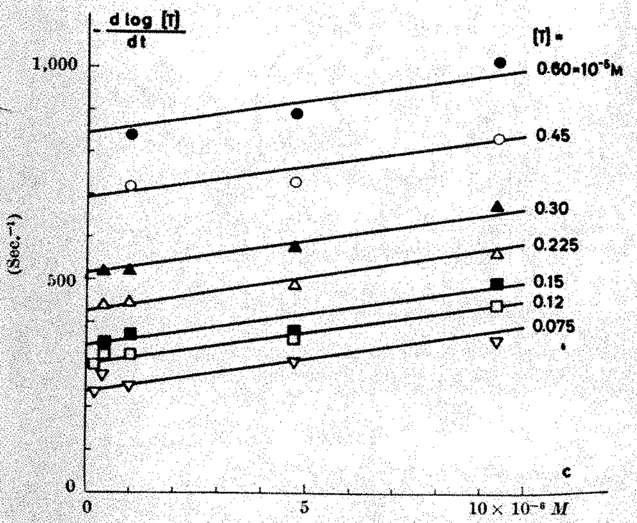

Fig. 2. The extrapolation of $-d\log(T)/dt$ to $c = 0$. The slope gives the value of k_2

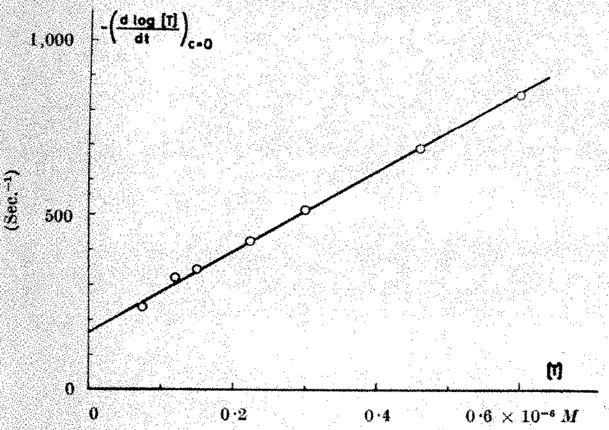

Fig. 3. The value of $-d\log(T)/dt$ at $c = 0$ from Fig. 2 plotted against (T). The slope of the line gives $k_3 - k_2$, and the intercept gives k_1

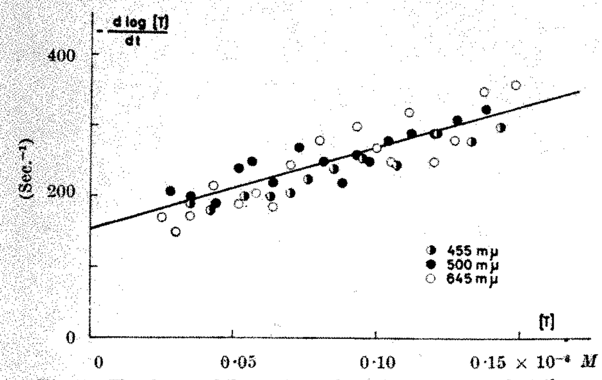

Fig. 4. The decay of the metastable state, as measured at three different wave-lengths, where the total concentration of chlorophyll *b* was 0·2 × 10⁻⁶ *M*

The kinetic measurements were carried out over the concentration range of 10^{-7} to 10^{-5} *M*, with optical path-lengths of 60 and 20 cm. The transient decay was studied both photographically and photoelectrically, principally the latter.

For all wave-lengths studied (that is, 410–645 mμ) the decay was in agreement with a scheme proposed by Livingston[5]. It may be represented as follows, where *T* indicates the metastable state and *S* the ground-state of chlorophyll *b* :

$$T \rightarrow S \tag{1}$$

$$T + S \rightarrow S + S \tag{2}$$

$$T + T \rightarrow S + S \tag{3}$$

Then, if the total concentration of chlorophyll *b*, $(T) + (S)$, is denoted by *c*,

$$-\frac{d(T)}{dt} = k_1(T) + k_2(T)(S) + k_3(T)^2 \tag{4}$$

$$-\frac{d\ln(T)}{dt} = k_1 + k_2 c + (k_3 - k_2)(T) \tag{5}$$

For the determination of the three constants in equation (5), we have relied chiefly on values obtained at 500 mμ. Extrapolations to $(T) = 0$ and $c = 0$ are needed, these being carried out in either order. Figs. 2 and 3 illustrate one of these possibilities. For each total concentration the decay-rate is determined at some selected values of the concentration (T) of the metastable state. For each (T), an extrapolation to $c = 0$ is performed (Fig. 2) to give $(d\log(T)/dt)_{c=0}$, the slope defining the constant k_2. The ordinates for $c = 0$ are plotted in Fig. 3 against (T), the intercept giving k_1 and the slope giving $k_3 - k_2$. Each point in Fig. 2 is based on two or three different experiments consisting of 10–30 oscillograms. The results for the three constants are :

$$k_1 = 0{\cdot}4_0 \times 10^3 \text{ sec.}^{-1}$$
$$k_2 = 0{\cdot}03_5 \times 10^9 \text{ sec.}^{-1}\, M^{-1}$$
$$k_3 = 2{\cdot}3_5 \times 10^9 \text{ sec.}^{-1}\, M^{-1}$$

In connexion with the determination of the absorption spectrum of the metastable state shown in Fig. 1, kinetic experiments were also performed photographically, these revealing four isosbestic wave-lengths. During the photoelectrical measurements of the kinetics, two of these wave-lengths, 418 and 474 mμ, were further confirmed. No change in extinction at these two wave-lengths was observed. From this it is concluded that only one metastable state is present under these experimental conditions. A further proof is the good agreement among the decay rates for different wave-lengths. This is illustrated in Fig. 4, where the same kinetics is obtained at the three wave-lengths shown.

The chlorophyll *b* was prepared by Zscheile and Comar's method[6]. A small amount of water was purposely left in the stock solution, thus avoiding difficulties in interpretation due to superdryness of the final solutions. The solutions were degassed by five cycles of freezing, evacuating and melting.

A detailed account of this work will appear in the near future.

The investigation was supported by a grant from the Rockefeller Foundation.

IN VITRO ANALYSIS OF A MAMMALIAN TUMOUR VIRUS

By Dr. LEO SACHS, Dr. MARIAN FOGEL and ERNEST WINOCOUR

Department of Experimental Biology, Weizmann Institute of Science,
Rehovoth, Israel

THE classical studies of Ellerman and Bang[1] and Rous[2] first demonstrated that viruses could be involved in the origin of neoplastic growth. Several tumour viruses have now been isolated from birds and frogs, and in mammals viruses are known to be associated with papilloma in rabbits and some other species, fibroma in rabbits, and mammary tumours in mice[3]. In 1951, Gross[4] reported his original observations on the viral origin of a spontaneous lymphatic leukæmia in mice. This observation has been fully confirmed[5], and since then viruses have been found to be associated with some other types of leukæmia[6], parotid tumours and sarcomas[7] and various other neoplasms in mice and hamsters[8]. All these observations in mammals, with the exception of those of Stewart *et al.*[8], have been made after inoculation of filtrates from a tumour directly into a susceptible host. It seems clear that even for the actual isolation of viruses such a procedure has limitations; and such studies, by themselves, can, of course, give little direct information on cell virus relationships. It would appear that an answer to the basic questions relating to tumour viruses in mammals can only be given by combining an *in vivo* with an *in vitro* analysis.

It has been shown by Stewart *et al.*[8] that a virus originating from a spontaneous lymphatic mouse leukæmia can be maintained in tissue culture, and that when harvested from such cultures it can produce a variety of tumours. We are indebted to Drs. Stewart and Eddy for sending us some of their line 3919 of this virus, which they have termed polyoma virus, and the present report deals with some *in vitro* studies with this material.

The polyoma virus was routinely grown in Petri dishes on monolayers of Swiss mouse embryos, incubated in a humidified atmosphere containing 10 per cent carbon dioxide[9], using a medium of 0·5 per cent lactalbumin hydrolysate in Earle's saline and 20 per cent horse serum. Our first passage in culture of the material received from Stewart and Eddy gave a clear cytopathogenic effect, as a result of which cells become detached from the glass, often in grape-like clusters, and degenerate; and a cytopathogenic effect with this virus has also recently been reported by these authors[10]. In addition to embryo, cells of adult mouse kidney and bone marrow were tested and a cytopathogenic effect was produced in both these tissues. The demonstration of an observable effect on cells in culture has made it possible to develop a plaque assay for this virus similar to that originally developed for viruses such as poliomyelitis[9]. The cytopathogenic effect could be localized into foci under agar; the technique will be described in detail elsewhere. Plaques appeared as small discrete foci of degenerate cells. Isolations from plaques should give pure lines of virus and these are being tested for the type of tumours that they produce.

Table 1. SPECTRUM OF RED BLOOD CELLS AGGLUTINATED BY POLYOMA VIRUS

Red blood cells	Hæmagglutination titre 1: Virus-infected t.c. fluid	Hæmagglutination titre 1: Normal t.c. fluid	Red blood cells	Hæmagglutination titre 1: Virus-infected t.c. fluid	Hæmagglutination titre 1: Normal t.c. fluid
Guinea pig	2,048	8	Sheep	512	—
Rat	256	128	Goat	—	—
Mouse (Swiss)	1,024.	64	Dog	1,024	4
Hamster	8	8	Cat	16	16
Frog (*Hyla arborea*)	4,096	16	Chick (1 day old)	1,024	8
Human (O)	128	8	Hen (adult)	2,048	—
Monkey			Turkey	2,048	8
(rhesus)	512	4	Pigeon	32	32
(patas)	16	8	Goose	16	16
(baboon)	32	4	Duck (*Anas coxhas*)	16	16
Horse	—	—	(*Anas moscant*)	512	16
Cow	—	—			

We have also found, as recently reported by Eddy *et al.*[10], that the polyoma virus can hæmagglutinate at refrigerator, but not at higher, temperatures. The spectrum of its agglutinability for red blood cells from different species is shown in Table 1. Guinea pig cells have been routinely used with titres up to 1 : 4,096. 0·15 c.c. of a 1 per cent suspension of red blood cells in saline was added to 0·5 c.c. of each dilution of virus, and the tests read after 3 hr. or overnight. The end-point used was that of a full agglutination of the red blood cells. The hæmagglutinating particles are stable after heating at 56° C. for 30 min., but destroyed after 30 min. at 66° C. When taken from the refrigerator and placed at room temperature, the agglutination is destroyed and the red blood cells settle normally. The virus is eluted readily at 37° C., and the cells after elution can again adsorb virus. Hæmagglutination inhibition was produced by antibodies against the virus, and titres up to 1 : 81,920 have been obtained.

With the establishment of the plaque and hæmagglutination assays, it became possible to make quantitative *in vitro* determinations on the growth of the virus in tissue culture.

Two separate experiments, using two different inocula, were carried out on the growth of the polyoma virus on mouse embryo monolayers (Table 2). In Exp. 1 there was no change of medium throughout the experiment so that the cumulative amount of virus could be determined. A series of monolayers were inoculated with virus (3 hr. absorption followed by washing), and at the time intervals shown in Table 2 the amount of virus in the medium (free virus) and in the medium plus cells (total virus) was determined by hæmagglutination. Total virus was determined after subjecting the entire cultures (medium plus cells) to five cycles of freeze thawing at − 20° C. In Exp. 2 a series of monolayers were inoculated as previously and the amount of virus released into the medium was determined during the first 24-hr. and two subsequent 48-hr. periods. After

Table 2. GROWTH OF POLYOMA VIRUS ON MOUSE EMBRYO MONOLAYERS

		B	8	256	128	—
	'Free virus' (Series 2) by plaque assay†	*A*	11	234	114	—

* Hæmagglutination titres expressed as reciprocal of complete hæmagglutination end-point per 0·5 ml. Hæmagglutination titre of control plates was 8.

† Plaque assay expressed as mean number of plaques (4 plates) per 0·2 ml. at 1 : 10 dilution.

Exp. 1, strong cytopathogenic effect after 7 days. Exp. 2, strong cytopathogenic effect and complete destruction of monolayer after 5 days.

each collection date all the cultures were washed and fresh medium added. This experiment was carried out in two series. In series 1 the samples tested at day 1, 3 and 5 were taken from the same plate in each of the four replicates (*A–D*). In series 2, the samples tested at day 1, 3 and 5 in the two replicates (*A* and *B*) were taken from different plates. The virus in series 1 was assayed by hæmagglutination and in series 2 by hæmagglutination and plaques. In all experiments the virus assayed by hæmagglutination was from supernatants after centrifugation at 3,000 r.p.m. in a clinical centrifuge for 10 min.

The results of both experiments clearly show that there has been multiplication of the virus on mouse embryo cultures, and that virus is released over a long period of time. Little or no virus could be detected during the first 24 hr., and the highest level of virus production and release in Exp. 2 was during the period between the first and third day. The drop in virus during the next 48-hr. period in this experiment may have been due to the early appearance of a strong cytopathogenic effect. It can also be seen from Exp. 2 that the results obtained from plaques follow that obtained by hæmagglutination. The results of Exp. 1 show that the free virus was less than the total virus throughout the experiment, indicating that a significant amount of virus produced remains associated with cells and is not released immediately into the medium. A similar situation has been noted in viruses such as vaccinia and sheep pox[11]. The behaviour of the polyoma seems to differ in some respects from that reported for the Rous chicken virus[12].

These results with the polyoma demonstrate that with the use of the plaque assay developed it is now possible to produce pure lines of mammalian tumour virus, and that furthermore it is now possible to use *in vitro* techniques both for the characterization of mammalian tumour viruses and for the analysis of cell virus relationships.

AGGREGATION OF COD MYOSIN DURING FROZEN STORAGE

By J. J. CONNELL

Food Investigation Organization, Department of Scientific and Industrial Research,
Torry Research Station, Aberdeen

MONODISPERSE cod myosin has a pronounced tendency to aggregate when neutral solutions of it are left undisturbed at 0° C.[1,2]. The aggregation is characterized by the appearance in the ultracentrifuge picture of the solution of at least one, and sometimes two, discrete components which sediment faster than myosin and which, on the basis of their sedimentation coefficients, can be identified as a side-to-side dimer and trimer, respectively. It has now been found that this aggregation proceeds in the frozen state.

Solutions of monodisperse cod myosin (0·4–0·6 per cent) in 0·45μ potassium chloride with 0·05μ phosphate buffer, *p*H 7·5, contained in $\frac{5}{8}$ in. × 2 in. thin-walled plastic tubes, were frozen by immersion in a bath of chloroform-solid carbon dioxide at about −78° and then stored for 3 or 4 days at −7, −14, −22, −29 and −78°. They were then thawed by placing the tubes in ice water so that the final temperatures never rose above 0°. Figs. 1 (*d–h*) show the ultracentrifuge pictures obtained immediately after the solutions were thawed. Fig. 1 also shows pictures of the original solution and the original solution after standing 3 days unfrozen at 0°. It is evident that (omitting Fig. 1*b*) least aggregation has occurred in the unfrozen solution kept at 0° and in the solution kept at −29° for 4 days, the amount of monomeric myosin in these solutions being still so great that the top of the schlieren peak is not registered and the typical bar effect parallel to the meniscus is produced. Most aggregation has occurred in the solution kept at −14° and −22°, most of the myosin having formed heavy polydisperse material which has sedimented to the bottom of the cell before the photographs were taken, leaving small residual amounts of monomeric and oligomeric myosin in the supernatant solution.

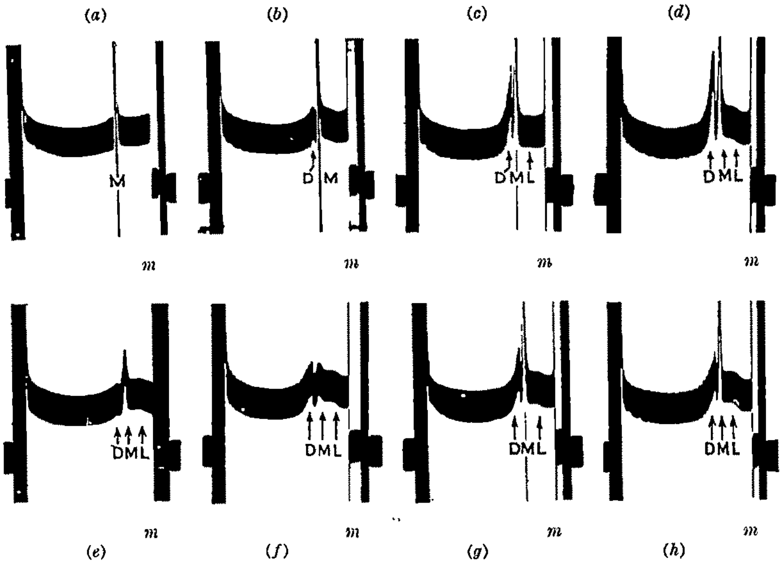

Fig. 1. Sedimentation pictures of cod myosin solutions. *a*, original solution; *b*, *a* frozen to − 78° and thawed at 0° five times in succession; *c*, *a* left unfrozen at 0° for 3 days; *d*, *e* and *f*, *a* frozen to − 78°, stored for 3 days at − 7, − 14 and − 20°, respectively, then thawed at 0°; *g* and *h*, *a* frozen to − 78°, stored for 4 days at −29 and −78°, then thawed at 0°. Sedimentation at 59,780 r.p.m. occurs from right to left. *m* is the meniscus; *D*, *M* and *L* denote, respectively, dimeric and monomeric myosin and a light component. Exposures taken: *a*, 96; *b*, 75; *c*, *d*, *e*, *g* and *h*, 69; and *f*, 53 min. after reaching full speed. Temperature of rotor: *a*, 2·20; *b*, 4·70; *c*, 1·95; *d*, 4·40; *e*, 5·30; *f*, 7·15; *g*, 2·25; and *h*, 3·65° C.

At −7° and −78° aggregation has proceeded to some intermediate stage.

This result has been confirmed with two other different preparations of cod myosin. Solutions kept frozen for about 7 days and then thawed, particularly those at −14° and −22°, often contain blobs of weak transparent gel and fine precipitates. The operation of freezing and thawing even when carried out five times in succession on the same solution produces only traces of material which sediments faster than myosin (Fig. 1*b*).

Two experiments with myosin frozen in solutions containing 0·45μ sodium chloride and 0·45μ potassium sulphate (both with 0·05μ phosphate buffer, *p*H 7·5) showed that the pattern of aggregation is different from that in solutions containing potassium chloride. In solutions containing 0·45μ sodium chloride aggregation is much the same at −7, −14 and −22° but less at −29 and −78° than at the higher temperatures; in solutions containing 0·45μ potassium sulphate aggregation is pronounced at −7° and becomes progressively less at the lower temperatures. These observations suggest that both the eutectic temperature of the solution (about −1·5, −11 and −21° for potassium sulphate, potassium chloride and sodium chloride, respectively) and the temperature of storage are important factors in determining the rate of aggregation. Snow[3] has suggested that the rate of insolubilization of haddock actomyosin during frozen storage of its solutions is greatest at temperatures below the eutectic point.

Fig. 1 also shows that a component (*L*), which sediments more slowly than myosin, is formed during frozen storage and possibly also during equivalent periods of storage in the unfrozen state at 0°. The largest amount of this presumed dissociation sub-unit of myosin appears to be produced at −78°.

The mechanism of these complex changes is unknown; but they occur without any appreciable intramolecular change because the specific rotation and numbers of sulphydryl groups titratable with N-ethylmaleimide do not change during the first 7 days storage at −7°, for example. It has been noted also that the aggregation of cod myosin in the unfrozen state at 0° apparently does not proceed by a conversion of sulphydryl groups into disulphide bridges because (1) the aggregation is not inhibited by the addition of 0·01 *M* monothiglycol, and (2) myosin the reactive sulphydryl groups of which have been blocked by N-ethylmaleimide aggregates just as rapidly as untreated myosin.

Further aspects of these changes are being investigated, particularly in relation to the toughness and loss of water-holding capacity which develop during the frozen storage of fish muscle. The development of toughness in stored fish must ultimately involve some sort of intermolecular cross-linking or aggregation reaction of the proteins. The changes occurring during the frozen storage of whole muscle have been often ascribed to protein 'denaturation'[4-9], the implication being that some form of unfolding or configurational alteration of the molecules occurs. However, the experiments described here suggest that some part, or the whole, of these changes may involve aggregation of native configurationally unchanged molecules. This notion is supported by a number of scattered observations. Thus, no change in the numbers of sulphydryl groups of that part of the fish actomyosin complex which remains soluble after frozen storage could be found[7,10]. (In one investigation[6], apparently random variations in the 'masked' sulphydryl groups of whole fish muscle during frozen storage did occur in some circumstances.) In addition, the apyrase activity of whole fish muscle does not decline during conditions of frozen storage which undoubtedly lead to the development of toughness of the tissue and insolubility of the myofibrillar proteins[11]. Partmann's suggestion[11] that the explanation for this phenomena lies in the fact that the *H*-meromyosin sub-unit, which possesses all the adenosine triphosphase activity of the myosin, is reported[12] to be unaffected by freezing while *L*-meromyosin is rendered insoluble, remains to be investigated.

This work was carried out as part of the programme of the Food Investigation Organization of the Department of Scientific and Industrial Research.

Verification of General Relativity by means of Artificial Planets

THE evidence from observation[1] for the relativity advance of the perihelia of planetary orbits depends primarily on the rate of advance of the perihelion of Mercury. I have discussed[2] the possibility of basing a verification of this result of general relativity on the motion of minor planets of high eccentricity, in particular on the motion of (1566) Icarus. La Paz[3] has pointed out the further possibility of a check based on observation of an artificial satellite of the Earth. The recent Russian success in creating an artificial planet of the Sun has removed from the realm of speculation the use of such a body in verifying the predictions of general relativity. The purpose of this communication is to show that the controllable orbit of an artificial planet can be selected to yield a very large relativity advance of perihelion under certain conditions.

The expression of general relativity for the angular advance ε (in radians) of a planetary perihelion per revolution is:

$$\varepsilon = 6\pi GM\,[c^2 a\,(1 - e^2)\,]^{-1} \qquad (1)$$

where a is the semi-major axis and e the eccentricity of the orbit, M is the mass of the Sun, G is the gravitational constant, and c is the speed of light. It will be assumed that propulsion of the artificial planet terminated in the immediate neighbourhood of the Earth. Hence, the minimum possible value of a is approximately $\frac{1}{2}$ A.U. (corresponding to $e \sim 1$), fixed by the fact that the aphelion point cannot lie inside the Earth's orbit. As in the corresponding case for a minor planet[2], it follows that a significantly large relativity advance for an artificial planet is possible only for large eccentricity.

When the approximation $e \sim 1$ is made, equation 1 can be written in the form:

$$\varepsilon = (3\pi GM/c^2)q^{-1} \qquad (2)$$

where $q = a\,(1 - e)$ is the perihelion distance of the planet's orbit from the Sun's centre. For the case in question, equation 2 states that the relativity advance per revolution depends only on the reciprocal of the perihelion distance. If the semi-major axis a is measured in astronomical units, the annual advance v (in radians) of the perihelion is:

$$v = \varepsilon/a^{3/2} \qquad (3)$$

since in this case the period P in years is given by $P = a^{3/2}$. In the same units, one must have:

$$2a - q \geqslant 1 \qquad (4)$$

if the aphelion point is not within the Earth's orbit. The minimum possible value of q in equation 2 clearly is fixed by $q = R_\odot$, where $R_\odot$ is the solar radius. The corresponding point of tangency of the orbit with the Sun's surface at perihelion is the only point of contact, since the semi-parameter (half the latus rectum) given by $p = a\,(1 - e^2)$ always exceeds the perihelion distance q for an elliptical orbit. The value $v_{\text{max.}}$ of the maximum possible perihelion advance v corresponding to the minima $q = R_\odot$ and $a = (1 + R_\odot)/2$ from (4) is:

$$v_{\text{max.}} = 11{\cdot}6'' \qquad (5)$$

annually. This figure can be compared with centennial advances of 43″ and 10″ for Mercury[1] and Icarus[2] respectively, which are less by orders of magnitude.

In practice, the grazing contact with the Sun to which equation 5 corresponds is undesirable, since the perihelion point must be selected so that loss of mass of the artificial planet in its passage through the extended atmosphere of the Sun is negligible. The effect on v of varying q (in terms of the solar radius as unit) is shown in Fig. 1, with the semi-major axis a (in A.U.) as parameter, over limits set by inequality 4. One sees that a reasonable range of q and a exists over which the perihelion advance v of the artificial planet exceeds that of Mercury. In the latter case, the value of v is shown in Fig. 1 as a function of q, although the approximation $e \sim 1$ is inapplicable (v is large because a is small). In common with the principal planets of mean distance greater than that of Mercury, the Russian artificial planet does not meet the condition of high eccentricity for a significant relativity advance. The pertinent elements of its orbit are $e = 0{\cdot}148$ and $a = 1{\cdot}16$ A.U., as reported in the current Press[4]. From equation 1, the corresponding relativity advance of perihelion is $v = 2{\cdot}7''$ per century, which is less than the figure (3·8″) for the Earth.

As is true also for the natural planets, the possibility of basing an observational test of the relativity formula 1 on the motion of an artificial planet depends on the possible precision in the measurement of the perihelion motion, as well as on the magnitude of the relativity advance. This precision can be

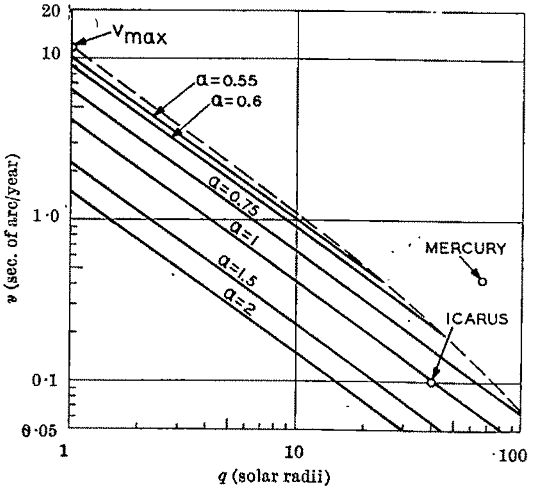

Fig. 1. The relativity advance v of the perihelion of an artificial planet of high eccentricity, as a function of its perihelion distance q (in units of the solar radius) from the Sun's centre, with the semi-major axis a (in astronomical units) as parameter. The dashed line corresponds to inequality (4). Values for Mercury and Icarus are shown for comparison. Scales are logarithmic

measured in the case of the principal planets by a figure of merit α defined by Clemence[1], and for the minor planets by a generalization of this parameter given by me[2]. It seems premature at this time to attempt evaluation of a corresponding figure of merit for an artificial planet. However, one important consideration associated with the factor l (the fraction of the period over which observations can be made) entering the figure of merit α can be noted. Because of the small size of an artificial planet relative to those of the observable minor planets, optical or radar observation is possible only when the object is in the immediate vicinity of the Earth. To optimize the number of passages in which observation is possible, it is accordingly necessary that the ratio of the planet's period to that of the Earth equal closely a ratio of small integers n and m. This condition requires that:

$$a \sim (n/m)^{2/3} \qquad (6)$$

for a in A.U. In time, of course, the effect of perturbations will tend to destroy the relationship 6, and this circumstance may ultimately limit the amount of data obtainable from an artificial planet, and the corresponding precision in fixing the relativity advance.

Effect of Magnetic Activity on Drifts of the *F*2 Region

OBSERVATIONS of ionospheric drift made at high-latitude stations by different methods has been examined by several investigators with the view of studying the dependence of speed and direction of drift on magnetic activity. From such studies, it has generally been concluded that speeds of drift of the $F2$ region increase with increase of magnetic activity. As it was found[1] that drifts of the $F2$ region at Waltair show a significantly different behaviour from those at high latitudes, we have examined the results of the $F2$ drifts at Waltair with the view of ascertaining the nature and the extent of this dependence on magnetic activity.

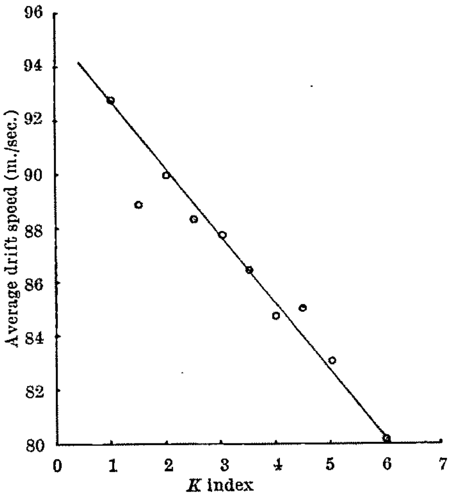

Fig. 1. Variation of speed of drift of the $F2$ region with geomagnetic K index

For the purpose of the present analysis, observations made at Waltair (mag. lat. 9° 30′ N.) of drifts of the $F2$ region obtained by the spaced receiver method over a period of 16 months during February 1956 to May 1958 are utilized. The observations were made at 0900, 1200 and 1500 hr. I.S.T. on most of the days during this period. The operating frequency is adjusted in the range 5·8–6·2 Mc./sec., so as to obtain reflexions from an equivalent height of about 300 km. On some of the days for which 24-hourly observations are available, the mean of the three observations around these particular three hours is taken to give smoothed and representative values for these hours. As an index of magnetic activity, the magnetic K indices published by the Alibag Magnetic Observatory are utilized for this study. At first the observations for all the three hours are grouped together and the speeds of drift corresponding to each value of K indices are sorted out and averaged. Fig. 1 shows a plot of the average speeds of drift thus obtained against the corresponding K indices. A total number of 466 observations were utilized for plotting this graph. A mean straight line drawn through all the points gives best fit, and reveals the interesting feature of decrease of mean drift speed of the $F2$ region with increase of magnetic activity in the range of 0–6, a result which is contrary to the exactly opposite conclusion drawn from high-latitude observations. A further interesting point is the more or less linear decrease of drift speed with magnetic K index. As the diurnal variation study of speed of drift at this station showed variations of speed of drift from hour to hour with maxima at noon and midnight, the results for each of the above three hours is also plotted separately against the K indices and the same trend of decrease of speed of drift with increase of K index is observed, the effect being, however, less for observations at 1500 hr.

Among the previous investigators, Briggs and Spencer[2] reported a progressive increase of speed of drift with K index for the range of values above 4, and Chapman[3] observed a linear variation of speed of drift with K index in the range of 1–4 and a more rapid variation above $K = 4$. The radio-astronomy results[4], on the other hand, indicated a more pronounced effect, and presumably these results refer to a height of 500 km. In the light of these earlier results, the present observations show an unusual behaviour which seems to be characteristic of low-latitude stations. In one respect, however, our results agree fairly well with the Cambridge results. Briggs and Spencer reported that the N.S. component is more or less unaffected by K index for the low range, while the E.W. component shows an increase on the western side. In the present investigation also, we noticed that the N.S. component remains more or less steady, while the E.W. component, which is towards west, decreases until it almost reaches very low values for high K indices.

A detailed account of this investigation will shortly be published elsewhere. We are indebted to the

Council of Scientific and Industrial Research (India) for supporting this investigation.

Bose–Einstein Statistics and Helium Films

FOLLOWING the proposal of London[1] that the peculiar transition in liquid helium may be due to the accumulation of a significant fraction of the total number of particles in the ground-state of a Bose–Einstein gaseous assembly, many attempts have been made to understand the behaviour of this liquid in terms of the quantum statistics of a Bose gas. Most of these investigations have been confined to the study of helium in bulk. A few years ago, Osborne[2] applied Bose–Einstein statistics to helium films and showed that for films thicker than about 10^{-7} cm., the transition temperature should be the same as that for bulk liquid, whereas films thinner than this are effectively two-dimensional and should have transition temperatures much lower than the bulk value. The monotonic lowering of the 'onset' temperature of superfluidity with decreasing film thickness, observed in the study of unsaturated helium films[3] (which are essentially three-dimensional), thus remained unexplained[4].

Since it is to be expected that the properties of a statistical assembly would be modified when at least one of its dimensions becomes comparable with the mean de Broglie wave-length of the particles, we believe that a proper analysis based upon the Bose–Einstein statistics should be able to explain the observed phenomenon. In the present communication it is shown that such a study is possible provided the eigenfunctions in the bounded continuum are enumerated more exactly than is ordinarily done. We have therefore calculated the total number of particles in an ideal Bose–Einstein gaseous assembly by the equation:

$$N = \sum_i \frac{g_i}{\exp(\alpha + \varepsilon_i/kT) - 1} \tag{1}$$

and while replacing the summation over states by an integral we use the expression[5]:

$$g(\varepsilon)\,\mathrm{d}\varepsilon = 2\pi V\left(\frac{2m}{h^2}\right)^{3/2} \varepsilon^{1/2}\left[1 + \frac{S}{8V}\left(\frac{h^2}{2m}\right)^{1/2} \frac{1}{\varepsilon^{1/2}}\right]\mathrm{d}\varepsilon \tag{2}$$

We have taken periodic boundary conditions, and S/V is the ratio of the surface area of the enclosure to its volume.

Now, for the degenerate case ($\alpha = 0$) the integral over the correction term in (2) diverges. This is because we have replaced the summation by integration. On physical grounds we should expect that, to a crude approximation, the final result should not be much different from the one calculated from (2) if we replace $\varepsilon^{1/2}$ in the correction term by its average value:

$$\overline{\varepsilon^{1/2}} = (kT)^{1/2}\,[\Gamma 2\zeta(2)]/[\Gamma 3/2\zeta(3/2)]$$

whence one gets at the transition temperature T_0:

$$N = V\left(\frac{2\pi mkT_0}{h^2}\right)^{3/2} \zeta(3/2)\left[1 + \frac{0{\cdot}176\,S}{V}\left(\frac{h^2}{2mkT_0}\right)^{1/2}\right] \tag{3}$$

For a cuboid the thickness t of which is much smaller than the other two sides, we have $S/V \simeq 2/t$. Expressing t in terms of the mean de Broglie wave-length, $h\,.\,(2mkT_0)^{-1/2}$, and T_0 as a fraction r of $T_0{}^*$ (the transition temperature for an infinitely large assembly, $S/V \rightarrow 0$), we may write:

$$1 = r^{3/2}[1 + 0{\cdot}352/t] \tag{4}$$

Equation (4) gives the variation of the transition temperature with the film thickness, as shown in Fig. 1. This is in good qualitative agreement with the experimental results of Long and Meyer[3].

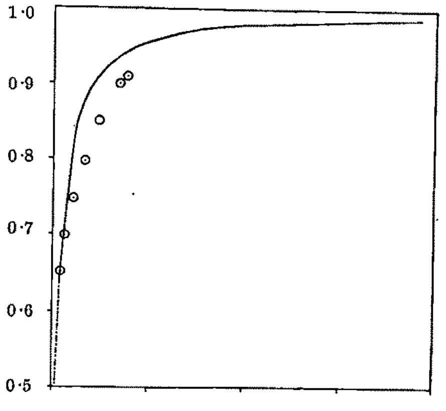

Fig. 1. The onset temperature of superfluidity T_0 (expressed as a fraction r of the transition temperature for bulk) as a function of film thickness t (in units of the mean de Broglie wave-length of the particles). ——, Theoretical curve; ⊙, experimental points of Long and Meyer

It may be noted here that the effect of the decreasing film thickness becomes important when it approaches about ten times the mean de Broglie wave-length. Further, it may be mentioned that the correction term in (4) becomes equal to unity for $t = 0{\cdot}352$, which implies a film of thickness 3·9 A. This limiting thickness is very close to the atomic distance in helium, which means that the three-dimensional approach, modified as above in order to include the effect of the surface term, is valid for films of thickness down to one atomic distance, below which the problem becomes two-dimensional and ceases to remain of practical interest.

A more detailed investigation along these lines, taking into account the interactions in the assembly, is in progress and will be reported elsewhere.

We wish to thank Prof. D. S. Kothari for suggesting this approach and for helpful discussions.

Effects of Arc Stage of Electrical Discharge on Ignition of Inflammable Gas

There is at present no generally accepted criterion of spark ignition. A widely held view is that energy delivered to the gas is the main criterion. Kravchenko[1] has advanced the thesis that the energy in the arc stage of the discharge is the sole criterion, and that other discharge conditions, such as glow, are incapable of giving rise to ignition. During the course of investigation on inductive break-spark ignitions, a number of records of current and voltage across the discharge were taken with high-speed oscilloscopes. A current of 185 m.amp. was interrupted in a 95-mH. inductance series circuit, and the resulting discharge was made to take place in an explosive mixture of 8·3 per cent methane in air. Oscillographic studies of similar discharges in air have been made by Nethercot and Rehfisch[2], with lower time-base sweep-speeds and non-simultaneous recording of current and voltage.

The patterns of arc, glow and multiple spark were found to be similar in the explosive mixture and in air. In general, most records showed arc stages lasting up to some 30 μsec. However, a number of records were obtained where a recognizable arc stage was limited to a few microseconds as in Fig. 1, or was non-existent as in Fig. 2, and these gave normal ignitions in an 8·3 per cent mixture of methane in air. To resolve detail in the multiple breakdowns shown in the records, simultaneous voltage and current recordings were taken at a time-base speed of 0·1 μsec./cm. Fig. 3 shows such a voltage record and Fig. 4 a corresponding current record, taken under conditions identical with those in Figs. 1 and 2. It is seen that nowhere is there a characteristic arc step; the wave carrying a superimposed high-frequency oscillation is likely to be due to the local oscillatory circuit at the contacts. A detailed examination of a number of records has shown that arcs are established at the two levels of 96 and 144 V. and glows at 384 V. It is therefore clear that ignition is not dependent on the arc stage of the discharge.

[2] Nethercot, W., and Rehfisch, T. J., E.R.A. Report *G/T* 217 (1948).

We agree entirely with Mr. Berz that an arc discharge is not essential for the ignition of inflammable gas, but we cannot agree with his statement that the multiple breakdowns shown in his records have none of the characteristics of an arc discharge. We suggest that they are transient arcs of very short duration in which the current is relatively constant as is the voltage, although its value is appreciably greater than that in a sustained discharge.

Multiple discharges, which often occur when inductive circuits are broken, are due to the capacitance associated with the circuit inductance and the opening contacts. At current break this capacitance is charged up at a rate which is dependent primarily on the values of the capacitance and the inductance. For short times the rate of rise of voltage is linear and the charging current is constant, as shown in the oscillograms of Figs. 3 and 4 of Mr. Berz's communication. When the voltage reaches the breakdown voltage of the gap, in this case about 400 V., the capacitive energy $\frac{1}{2}CV^2$ is rapidly discharged through the gap by the establishment of a short transient arc. The capacitance is then recharged through the inductance and the cycle is repeated until the breakdown voltage of the gap rises with increasing gap-width to a value which is greater than the peak value of the open-circuit oscillation.

From the results provided by Mr. Berz's oscillograms it is possible to deduce that the capacitance in his circuit is about 100 pF., and also that the voltage during the short discharge is about 130 V., which is in reasonable agreement with one of the values he has found for the establishment of an arc. The energy dissipated in each of these short arcs is about 8 microjoules, so that several hundred of them, as shown in the oscillograms of Figs. 1 and 2, are needed to give the total energy of a millijoule or so which is required for the ignition of a methane/air mixture under these conditions.

A Source of Natural Tin Whiskers

SOME years ago, when metal whiskers were discovered growing on plated surfaces in electrical transmission apparatus[1], many investigators began searching for places where natural whiskers might be found essentially undisturbed for many years. A brief reflexion will indicate that such places are not common. Even in museums, articles are cleaned periodically so that natural whiskers which might be on their surfaces are removed.

As a collector of military small arms and accessories, I chanced to discover an excellent source of tin whiskers in almost every German bayonet scabbard from the period before the First World War to the Second World War. The steel retainer springs which hold the bayonet in the steel scabbard were coated with tin to resist corrosion. One has only to remove these springs to observe a lush growth of natural tin whiskers on their surfaces. Fig. 1 shows such a growth on springs from a German bayonet scabbard of the First World War. Growth of whiskers is not entirely general over the free surface of the springs, but appears to be confined mainly to certain areas of relatively high activity. These areas may comprise as much as 80 per cent of the free surface. Patchy growth probably results from an uneven thickness of the tin coating. Such a variation of growth of whiskers with coating thickness has been established by experiment[1]. Retainer springs of the Second World War exhibit similar patterns of incidence of whiskers on their surfaces.

Under high magnification, the whiskers appear to have round or elliptical cross-sections and their surfaces are quite clean and reflective. They exhibit a variety of habits, including straight spires, coiled filaments, kinked spires, and branched whiskers, with the majority being straight. Whiskers from the First World War period commonly reach 5 mm. in length, a few being as long as 12 mm. It is clear from the geometry of the bayonet scabbard that the 12-mm. whiskers, which are about 1μ in diameter, must have grown along the inside wall of the scabbard. However, they are not generally kinked. As expected, much shorter whiskers, having a maximum length of about 2 mm., were noted on the Second World War springs. The variation in diameters between individual whiskers from both First and Second World War springs was 1–10μ.

One of the difficulties with tin whiskers has been the scarcity of specimens of sufficient length for experimental investigation. However, whiskers from the First World War bayonet scabbard springs are quite adequate for most types of testing, and they are plentiful. Undoubtedly, many other sources of long tin whiskers exist, such as the inside surfaces of old tin-coated canteens and cartridge boxes.

Structure of Kish and Other Graphites

FRANKLIN[1] assumed that there were only two types of layer in graphitic carbons: parallel and oriented and parallel but disoriented layers. The disoriented layers occur randomly with a probability p, between the oriented layers. From this assumption she obtained a simple formula for the intensity curve in reciprocal space:

$$I = (1 - U^2)/(1 + U^2 - 2U \cos \pi l)$$

where l is the crystallographic index and $U = 1 - p$. This is a special case of the more general intensity formula for X-rays scattered from disordered layer lattices[2,3]. All Franklin's intensity curves of the $11\bar{2}2$ line, obtained with graphitized carbons heated to between 1,720° and 3,000° C., are very close to the theoretical curves, estimated p values ranging from 0·9 to 0·1. Bacon[4] showed that the formula was also applicable to well-crystallized graphites, such as Ceylon graphite, and to three artificial samples.

Kish and flake graphite extracted from grey cast irons[5] were studied similarly. A 24-cm. Debye–Scherrer camera with a thermostat device was used. For the 0008 and $11\bar{2}2$ lines nickel $K\alpha_1$ (θ, 81°) and chromium $K\alpha_1$ (θ, 82°) radiations were used respectively. For the 0008 line pressed specimens 0·7 mm. thick and 6 mm. in diameter were used in order to concentrate the scattering on the $000l$ lines. For the $11\bar{2}2$ line ordinary rod specimens, diameter 0·7 mm., were used.

The separation of the α_1 line from the $\alpha_1\alpha_2$ doublet and the corrections for the geometrical broadening were carried out by Bracewell's method[6]. In evaluating numerically the integral equation, the geometrical broadening was assumed to be given by the profile of the $11\bar{2}0$ line.

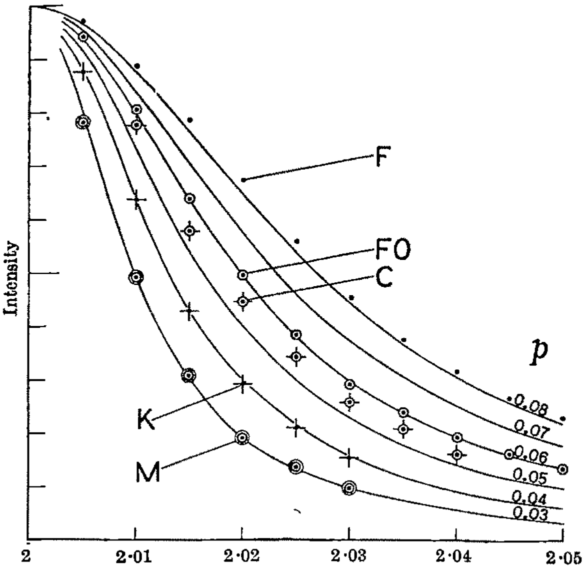

Fig. 1. The intensity distribution in reciprocal space derived from the powder line $11\bar{2}2$ of various graphites

The theoretical intensity curves for the $11\bar{2}2$ line in reciprocal space are shown in Fig. 1. The observed points *F*, *FO*, *C*, *K* and *M* were determined from microphotometer records obtained with the following samples: (*F*) Flake graphite extracted from grey cast iron, used in a previous study[5]. (*FO*) The same sample of flake graphite wet-oxidized for 12 hr. as previously described[5]. After the treatment *p* decreased from 0·082 to 0·060. (*C*) Ceylon graphite ground in an agate mortar after mixing the sample with small amounts of rock salt and treating the mixture with hydrochloric and hydrofluoric acids. The grain-size was 0·01–0·1 mm.; *p* was estimated to be 0·055, whereas Bacon's result was 0·050. A slight increase in the proportion of disordered layers was presumably caused by the grinding. (*K*) Kish graphite obtained from the Kamaishi mine, Japan. The sample was neither mechanically nor chemically treated. When it was examined under a microscope well-crystallized pure flakes with flat surfaces were observed. The grain size was 0·1–0·7 mm. Recently, Walker[7] found smaller interplanar distances than normal in untreated Kish containing 48 per cent ash. He attributed this to internal pressures produced when the Kish was formed from molten iron. In my sample no contraction of spacings greater than 0·0001 A., as compared with the Ceylon graphite, was observed. (*M*) Original flakes of Madagascar graphite. The grain size was 0·4–0·8 mm.

As will be readily seen from Fig. 1, the agreement between the observed points and the theoretical curves is striking.

Surface Charges produced on Insulators by Short- and Long-time Ionization

WITH the use of a rotating-probe electrometer[1], high-resolution measurements of induced surface charges have revealed some significant charge differences between short- and long-time periods of ionization. This difference may lead to a better understanding of the mechanism of dielectric failure in the presence of gaseous ionization.

The induced voltage charge pattern on the surface of polyethylene, as measured with the rotating probe electrometer immediately after a d.c. discharge at the inception voltage of a 1-mm. uniform field gap, is shown in the oscillograph trace drawing No. I (Fig. 1). The charge pattern measured a month later is essentially the same as shown in trace No. II (Fig. 1). These patterns show that the polarity of the charge is the polarity of the electrode facing the dielectric surface, that the magnitude of charge is uniform, and that it remains virtually unchanged at normal room conditions for a long period of time.

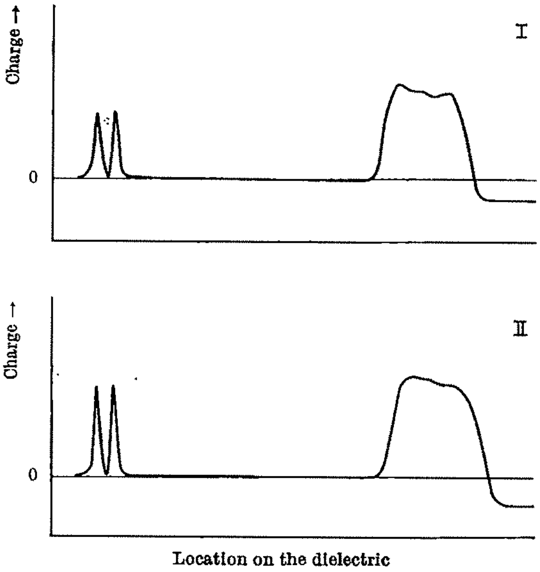

Fig. 1. Positive charge patterns on polyethylene after d.c. discharge (I) and one month later (II)

As shown by Mason[2], if the polarity of the field is reversed, the influence of such a charge could reduce the inception voltage of the gap by as much as 50 per cent. In this case the influence of the charge could be effective a month after its inception. In all these charge measurements marker pips on the left side of the cathode-ray oscilloscope trace are obtained from two wires (0·25 diam.) mounted vertically in plastic 3·5 mm. apart and maintained at a d.c. potential of + 500 volts above ground. The rotating probe picks up an induced voltage from these wires as it passes over the wires and the charged surface. In this manner the magnitude and charge diameter can be determined by measuring the width of the charge pattern at the points of inflexion.

Short-duration 60-cycle ionization tests were made between two parallel polyester resin surfaces separated by 1 mm. A potential of 5·6 kVp. was applied for $1\frac{1}{2}$ cycles.

The charge on both surfaces was then measured at the discharge site. The cathode-ray oscilloscope trace drawings are shown in Fig. 2. The positive charge

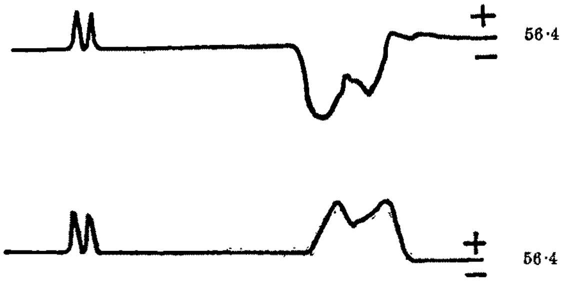

Fig. 2. Charge pattern on opposed surfaces of polyester resin after breakdown at 60 c./s.

on one surface is accompanied by a negative charge on the opposite surface. The charge patterns are not as uniform as obtained from the single discharge shown in Fig. 1. This is probably caused by some neutralization of charge during the polarity reversals; however, the polarity is still essentially determined by the polarity of the opposite electrode at the last half-cycle.

For an ionization test of long duration a stainless-steel electrode (2·54 cm. diam.) of 0·318 cm. radius was used to form a uniform 1-mm. gap to a polyester resin surface. Ionization tests were run at an a.c. voltage of 5·6 kVp. for 27 hr. The sample was removed from test and the charge pattern was obtained two days later as shown in Fig. 3. The charge trace obtained with the rotating probe shows that the charge polarity is no longer determined by the polarity of the last voltage-cycle; but we find small areas of both high positive and negative charge side by side. Furthermore, the charges are not easily removed as in the case of the short-duration induced charges of Figs. 1 and 2. This is readily accomplished by breathing moist air on the surface or by radiation with polonium, in spite of the fact that short-duration induced charges remain over long periods of time under normal conditions.

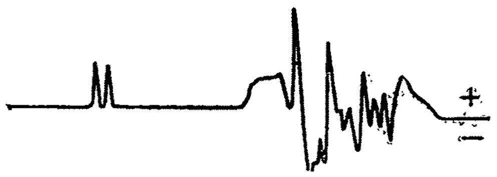

Fig. 3. Charge pattern on polyester resin after a.c. discharge for 27 hr.

It is known that the longer period of ionization results in the breaking of molecular bonds of the polyester resin; but it was not expected that this would result in large differences in charge polarity. On the contrary, it was anticipated that this would result in smoothing out the charges due to the increased surface conduction which is known to occur.

It is believed that longer periods of ionization result in higher energy discharges at selective sites which induce electrons to penetrate deeper into the dielectric, and that this accounts for the high positive and negative charges which occur close to each other and most probably indicate the site where selective erosion occurs. Thomas[3] concluded that negative discharges cause electrons to penetrate into the surface of the dielectric, where they are strongly bound and not easily reached by positive ions. It would appear from the foregoing measurements, made possible by the high resolution of the rotating probe, that there is some support for his conclusions.

CHEMISTRY

Synthesis of Colour Centres in Silica and their Thermoluminescence

THE colour centre which is responsible for the colour of smoky quartz has been described by O'Brien[1]. The precursor depends upon an aluminium ion substituted for silicon with an associated interstitial lithium ion for charge compensation. The centre consists of a hole trapped in the vicinity of the substitutional aluminium, the lithium having trapped an electron and migrated from the scene. We have now found that combinations of other ions with aluminium in silica powder produce an analogous centre under γ-radiation and have investigated the thermoluminescence of the pure and doped powders after exposure to γ-radiation.

The silica powder was doped by wetting it with solutions of the impurities and heating to 1,500° C. The undoped powder remained colourless after exposure to 10^6 r. γ-radiation from cobalt-60. Powder doped with 0·01 aluminium plus 0·01 lithium became a deep bluish-purple with the same dose. Samples doped with aluminium alone remained colourless after exposure. Cohen[2] showed by his measurements of anisotropy of the absorption that the aluminium must be substitutional. Substitution of aluminium for silicon ion requires charge compensation by a second ion such as that of lithium.

In several experiments lithium was replaced by other ions selected to supply the excess positive charge without necessarily supplying electron traps. Silver, magnesium and phosphorus, when added in combination with aluminium, produced coloration under radiation. Silver may be considered to have an action similar to lithium in being present interstitially and in providing an electron trap. Phosphorus, on the other hand, should be considered substitutional because of its high charge and normal four-fold co-ordination with oxygen. Magnesium must be considered intermediate. These experiments allow us to generalize the impurity centre described by O'Brien.

The undoped silica powder which showed no coloration after exposure had a very intense thermoluminescence with a maximum at about 280° C. when heated at 4 deg. C./min. The exposed silica (aluminium, lithium) showed luminescence maxima in the same region but with lower intensities. The luminescence of silica (0·01 aluminium, 0·01 lithium) was measured for several dose-levels. Although the coloration in these samples increased with dose, the integrated thermoluminescence went through a maximum. The luminescence of the pure silica sample was considered due to a process in which interstitial oxygens plus trapped holes are annihilated with oxygen vacancies plus trapped electrons; Mitchell and Paige[3] had proposed such centres, corresponding to two absorption bands in the ultra-violet region. The quenching of the luminescence of the aluminium centres is evidence for the interaction of these and the ultra-violet absorbing centres. The probability of the interaction would be expected to increase as the concentrations increased and therefore the luminescence showed a maximum at an intermediate dose.

Lithium can play a predominant part in the interaction of these centres while bleaching. The lithium in an interstitial position would be quite mobile, especially after being discharged by electron capture. Phosphorus ions, as well as lithium ions, can stabilize the aluminium in the substitutional position required in the precursor. However, the low mobility of the substitutional phosphorus in comparison with the high mobility of the discharged lithium should have a strong influence on the degree of interaction of the centre upon bleaching. It is planned to extend the investigation of thermoluminescence to silica (aluminium, phosphorus) to test this proposal, and to fused silica with controlled impurities so that the absorption bands can be studied and correlated with the luminescence.

Beta-Polymorphs of Uranium and Thorium Disilicides

Thorium disilicide was first described by Brauer and Mitius[1], who isolated single crystals and reported the crystal structure to be tetragonal with the space group *I*4/*amd*. Later, Zachariasen[2] described an isostructural uranium disilicide observed initially during metallurgical examinations by Kaufmann, Cullity and Bitsianes[3]. Another phase, thought by Kaufmann *et al.* to be U_2Si_3 and also studied by Zachariasen, was found to have a hexagonal crystal structure of the AlB_2-type, space group *C*6/*mmm*. The crystal structure results led Zachariasen to suggest that this compound was a second form of uranium disilicide and he designated it β-USi_2. The tetragonal uranium and thorium disilicides accordingly became the alpha forms. More recently, Jacobson, Freeman, Tharp and Searcy[4] obtained a thorium silicide isostructural with Zachariasen's β-USi_2, but observed that the silicon content was lower than that of α-$ThSi_2$. They used the description 'β-$ThSi_2$' but suggested that the true composition was $ThSi_{1\cdot5\pm0\cdot2}$.

We have prepared all the above phases by arc-melting and have examined them by metallographic and X-ray diffraction techniques. A noticeable feature of the preparations is the formation of 'β-USi_2' and 'β-$ThSi_2$' from mixtures containing 62–63 atomic per cent silicon, compared with the 66·7 atomic per cent required for the formation of the alpha disilicides. The compositions of these so-called beta phases accordingly appear to be U_3Si_5 and Th_3Si_5. Our values for the structure cell dimensions are:

U_3Si_5: $a_0 = 3{\cdot}843 \pm 0{\cdot}001$ A.; $c_0 = 4{\cdot}069 \pm 0{\cdot}001$ A.

Th_3Si_5: $a_0 = 3{\cdot}985 \pm 0{\cdot}001$ A.; $c_0 = 4{\cdot}228 \pm 0{\cdot}001$ A.

During an investigation into reactions between the silicides of uranium and thorium and liquid bismuth, two new silicide phases have been isolated. X-ray analysis shows that they are hexagonal with space group *C*6/*mmm*. These new phases, like the above M_3Si_5 compounds, have the AlB_2-type crystal structure, but the cell dimensions are different and, in particular, the axial ratio $c/a < 1$ compared with $c/a > 1$ for the M_3Si_5 compounds.

Heat treatment of the new thorium–silicon compound in the temperature-range 1,200–1,300° C. transforms it into α-$ThSi_2$, while heat treatment of α-$ThSi_2$ at 850° C. yields the new thorium–silicon phase. It is clear that this compound is in fact the true β-$ThSi_2$ and the analogous uranium compound the true β-USi_2. The structure cell dimensions obtained from X-ray diffraction results are:

β-USi_2: $a_0 = 4{\cdot}028 \pm 0{\cdot}001$ A.; $c_0 = 3{\cdot}852 \pm 0{\cdot}001$ A.

β-$ThSi_2$: $a_0 = 4{\cdot}136 \pm 0{\cdot}001$ A.; $c_0 = 4{\cdot}126 \pm 0{\cdot}001$ A.

Structural characteristics and structure-cell dimensions of the alpha and new beta polymorphs have been compared and a mechanism has been deduced to explain the structure transformation. Furthermore, it appears probable that the atomic arrangements of the M_3Si_5 structure can be derived from that of the β-structure by omission of one-sixth of the silicon atoms. As a consequence, the axial ratio changes from a value less than unity in the beta structure to a value greater than unity in the M_3Si_5 structure.

A more complete and detailed account of the work outlined above is in preparation.

Effect of the Carrier Gas on the Sensitivity of a Thermal-conductivity Detector in Gas Chromatography

In a recent communication[1], the sensitivity, dt/dx, of a thermal-conductivity cell to small amounts of organic vapours was derived from:

$$t_1 - t_0 = a/K_1 \qquad (1)$$

where t_1 and t_0 are the temperatures of the hot wire and body of the cell respectively, a is constant, and K_1 is the thermal conductivity of the carrier gas. The sensitivity was then shown to be:

$$\frac{dt}{dx} = -\frac{a(K_1 - K_2)}{K_1^2}, \text{ approximately} \qquad (2)$$

where K_2 is the thermal conductivity of the organic vapour and x is its concentration in the carrier gas. From equation 2, carrier gases of low thermal conductivity would be expected to produce the highest sensitivities. However, in practice a is usually varied, and sensitivities should be compared at equal values of t_1. Carrier gases of high thermal conductivity would then give the highest sensitivities.

An expression for a can be derived from a heat-balance equation that considers only the heat loss, from the wire, due to the thermal conductivity of the gas:

$$\frac{I^2R}{J} = CK_1\,(t_1 - t_0) \qquad (3)$$

where I is the current to the hot wire, R is the resistance of the wire at t_1, J is Joule's constant, and C is a constant for a given cell that depends only on the cell geometry. Rearranging gives:

$$t_1 - t_0 = \left(\frac{I^2R}{JC}\right)\frac{1}{K_1} \qquad (4)$$

From equations 1 and 4:

$$a = \frac{I^2R}{JC} \qquad (5)$$

Therefore, any change in current (I) or voltage (IR) changes a.

In practice, when the carrier gas is changed, current or voltage is adjusted to permit operating at a high wire temperature, where sensitivity is high. To maintain this wire temperature, a must vary with the thermal conductivity of the carrier gas, as shown by equation 1. Then, a/K_1 is constant, and, by rearranging equation 2:

$$\frac{dt}{dx} = \frac{a}{K_1}\left(1 - \frac{K_2}{K_1}\right) \qquad (6)$$

In this case, sensitivity will depend on the factor, $1 - \frac{K_2}{K_1}$; which is largest for the highest value of K_1. For this reason, gases of high thermal conductivity, such as hydrogen or helium, are preferred for maximum sensitivity in the detection of organic vapours.

The increase in cell sensitivity with carrier-gas thermal conductivity has been confirmed by measuring the output voltages developed with prepared mixtures of hydrocarbons or methanol in helium or nitrogen. Table 1 shows the voltages obtained at two levels of cell and wire temperature.

Table 1. EFFECT OF CARRIER GAS ON OUTPUT

° C. t_1	t_0	Vapour	Output, millivolts for 1 mole per cent vapour in: Helium	Nitrogen
100	25	*n*-hexane	21·2	2·20
100	25	methanol	11·0	0·45
200	150	benzene	9·9	0·29
200	150	*cyclo*hexane	10·8	0·20
200	150	*n*-hexane	11·5	0·23

Studies under way in our laboratories will illustrate further disadvantages of using carrier gases of low thermal conductivity.

L. J. SCHMAUCH
R. A. DINERSTEIN

Research and Development Department,
Standard Oil Company (Indiana),
Whiting, Indiana. Jan. 23.

Ray, N. H., *Nature*, **182**, 1663 (1958).

IT is quite true that the sensitivity of the detector would be higher with a carrier gas of high thermal conductivity, provided that the hot wire can be maintained at the same temperature. In practice, however, it is not always possible to achieve this because the bridge supply voltage is generally fixed by the makers of the instrument at a level which permits safe operation with a gas of low conductivity, and to increase the bridge voltage may necessitate modification to the electrical circuit of the instrument.

There is a further advantage with a carrier gas of low thermal conductivity; the thermal conductivities of organic gases increase more rapidly with temperature than those of monatomic gases such as argon and helium, so that if the operating temperature is raised the thermal conductivity difference, and hence the sensitivity, increases if a carrier of low conductivity is used; whereas with helium the reverse is the case, as shown in Table 1 of Dr. Dinerstein's communication.

Separation of Strontium-90 from Calcium

ONE of the main difficulties in determining the strontium-90 content of biological materials such as milk, bone and coral is the separation of strontium from the large amounts of calcium which accompany it. In an endeavour to avoid the rather tedious and time-consuming method based on the insolubility of strontium salts in strong nitric acid[1], various ion-exchange methods have been developed[2-5] in which the alkaline earth ions have first been absorbed on to a cation exchange resin and then successively eluted by agents such as lactate and citrate at a controlled *p*H. Although the amount of strontium in such samples is very small, these methods require the use of a relatively large column of sufficient exchange capacity to absorb at least part of the accompanying calcium as well as the strontium.

In view of the differing stability constants of the calcium and strontium ethylenediamine tetraacetic acid complexes (log $K_{1\mathrm{Sr}} = 8{\cdot}63$, log $K_{1\mathrm{Ca}} = 11{\cdot}0$)[6], a study was made of the absorption of these elements by a cation exchange resin, 'Zeo-Karb 225', in the presence of ethylenediamine tetraacetic acid over the *p*H-range 3–7. In each experiment 25 mgm. of strontium or calcium ions and 1 gm. of disodium ethylenediamine tetraacetic acid were used with a 10-ml. resin column (0·9 cm. internal diam.) in the sodium

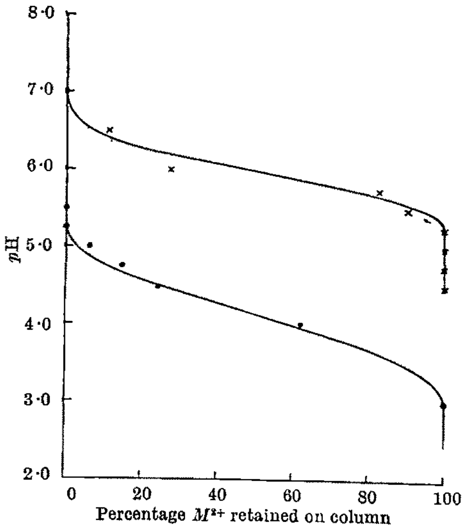

Fig. 1. Effect of *p*H on the removal of strontium (×) and calcium (●) from a solution of ethylenediamine tetraacetic acid by 'Zeo-Karb 225' cation-exchange resin column

form. It is seen from Fig. 1 that at *p*H 5·25, strontium, present in the cationic form, is quantitatively retained on the resin, while calcium is complexed by the ethylenediamine tetraacetic acid and passes through.

These results were confirmed by using the method to separate strontium from prepared strontium–calcium mixtures to which had been added calcium-45 as tracer. The recovery of strontium was checked by eluting the resin with 3 *N* hydrochloric acid and precipitating the strontium as carbonate and weighing. The activity of the carbonate precipitate gave a measure of the degree of contamination of the strontium with calcium. This was shown to be less than 1 per cent.

This ion-exchange recovery of strontium from strontium–calcium mixtures is achieved with the use of very small columns, and should be capable of application to the simple determination of strontium-90 on a routine basis, considerably reducing the time required for each determination.

I wish to acknowledge the assistance of Miss M. Barnett with the experimental work.

Detection of Keto-Acids

Most of the reported chromatographic work on the identification of keto-acids has involved the paper chromatography of a derivative, usually the 2,4-dinitrophenylhydrazone. A simple technique has been developed in this Laboratory whereby acidic materials which may contain keto-acids are chromatographed directly on Whatman No. 1 paper using a solvent containing ethyl acetate/acetic acid/water (60 : 25 : 15 v/v). After irrigation and drying, the papers are sprayed with a saturated alcoholic solution of 2,4-dinitrophenylhydrazine, dried with hot air for 5 min., and then sprayed with an approximately 5 per cent solution of potassium hydroxide in 90 per cent ethanol. The 2,4-dinitrophenylhydrazones which have been formed *in situ* react to give a variety of colours against an almost colourless background. In general, the derivatives of α-dicarbonyl compounds give colours ranging from light blue to dark purple. Derivatives of other carbonyl compounds produce yellow, red or brown spots. The colour given by any one of these derivatives is often distinctive for that compound, and may sometimes serve to differentiate between keto-acids with similar R_F values.

This method has proved useful recently in work on the ozonization of aqueous solutions of simple aliphatic acids, when mesoxalic acid may be produced. The oxidation products are chromatographed using a method developed here in which a *p*H indicator is incorporated in the solvent[1]. Mesoxalic acid or other keto-acids may have R_F values similar to those of other non-ketonic acids, and accordingly a second chromatogram without *p*H indicator is run and treated in the way described.

As little as 5 μgm. mesoxalic acid can readily be detected by this method.

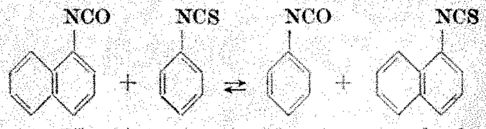
Equilibration of *iso*Cyanates and *iso*Thiocyanates

*iso*Thiocyanates have been prepared by several methods[1-4]; I have recently found that they can also be prepared conveniently by the equilibration of *iso*cyanate and *iso*thiocyanate groups. This equilibration occurs slowly at elevated temperatures and appears to be generally applicable to the preparation of *iso*thiocyanates and mixed *iso*cyanates–*iso*thiocyanates.

The reaction is illustrated by the following equation for the preparation of naphthyl *iso*thiocyanate :



This equilibration reaction may proceed through dimer formation. The yields obtained are fair, and considerable residue is formed. Decomposition leading to tar formation may be caused by the prolonged time at considerably elevated temperature required to establish equilibrium. Further study of the reaction and its variables, particularly acceleration of equilibrium formation by catalytic action, might greatly improve the yields.

25 gm. α-naphthyl *iso*cyanate (Matheson, Coleman and Bell) and 21 gm. phenyl *iso*thiocyanate (Matheson, Coleman and Bell) were mixed and heated, with stirring, under reflux at a pot temperature of 215–225° C. for 14 hr. During this period the reaction mixture turned yellow and gradually dark brown. Distillation of the reaction mixture yielded four fractions : 12·3 gm. distillate boiling at 164–168° C. at atmospheric pressure ; 4·5 gm. distillate boiling at 44–46° C. at 2–3 mm. mercury ; 3·4 gm. distillate boiling at 85–90° C. at 1–2 mm. mercury ; 13·6 gm. material boiling at 109–111° C. at 1 mm. mercury. This last fraction solidified on cooling to room temperature. A dark brown tarry residue (8·2 gm.) was left in the reaction flask. The solid material (m.p. 46–54° C.) was dissolved in toluene, the small amount of insoluble material filtered off and the toluene stripped off. The resulting white solid, α-naphthyl *iso*thiocyanate, weighed 12·8 gm. and melted at 56·7–57·5° C.

p-Bromophenyl *iso*thiocyanate (m.p. 61·6–62·0° C.) was prepared by an identical procedure in 35 per cent yield.

Structure of Malvalic Acid and Some Related C_{18} and C_{19} *Cyclo*propane Fatty Acids

In recent years an interesting group of fatty acids containing a *cyclo*propane or a *cyclo*propene ring has been isolated from natural products or synthesized. This work followed the discovery by Hofmann *et al.*[1,2] of a biologically active $C_{19}H_{36}O_2$ *cyclo*propane fatty acid, lactobacillic acid, in the lipides of *Lactobacillus arabinosus* and *L. casei*. Four more C_{19} acids of this type were synthesized[3,4]—the DL, *cis* and *trans*, 9-10 and 11-12, methylene octadecanoic acids. The crystal structures of two of these racemates have been studied[5,6], namely, the DL *trans* 9-10 and DL *cis* 11-12, and shown to have the characteristic straight- and bent-chain configurations illustrated in the electron density Fourier projections in Figs. 1 and 2. From the similarity in the diffraction data, the other two racemates are believed to be structurally isomorphous[7] in the *trans* and *cis* series, respectively. Of these, the DL *cis* 9-10 acid was shown[7] to be identical with the dihydrosterculic acid obtained[4] by hydrogenation of the sterculic acid[8], $C_{19}H_{34}O_2$, from the kernel oil of the tropical tree *Sterculia foetida*.

Lactobacillic acid itself had previously been identified with the phytomonic acid from the lipides of the plant pathogen *Agrobacterium* (*Phytomonas*) *tumefaciens*) which was studied earlier[9,10] but not recognized as a *cyclo*propane acid. From chemical and crystallographic evidence[11] it is now considered to be D or L *cis* 11-12 methylene octadecanoic acid, but this has yet to be completely confirmed by chemical synthesis or single-crystal structure analysis.

More recently, two C_{18} *cyclo*propane fatty acids have been reported, dihydrobombacic acid from the bombacic acid of kapok seed oil[12], and dihydromalvalic acid by hydrogenation of the malvalic acid from the leaves and seeds of *Malva verticillata* and *M. parviflora* and from cotton seed[13,14].

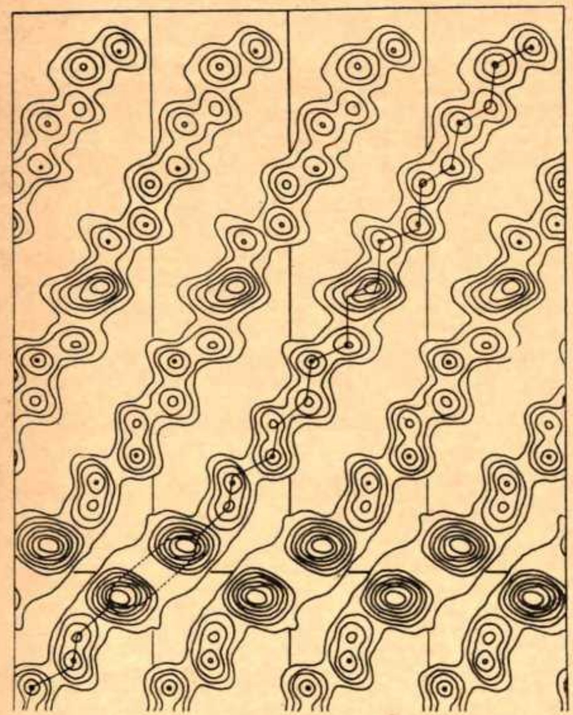

Fig. 1. DL *trans* 9-10 methylene octadecanoic acid

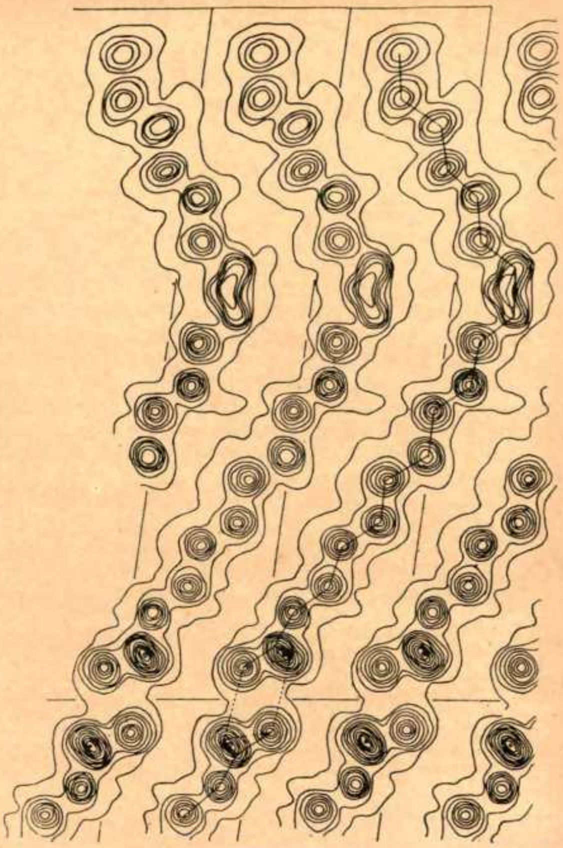

Fig. 2. DL *cis* 11-12 methylene octadecanoic acid

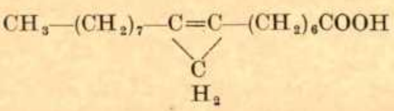
We have carried out a crystal structure analysis of dihydromalvalic acid and have shown it to be DL *cis* 8-9 methylene heptadecanoic acid, that is, DL-*cis*-7-(2-octa *cyclo*propyl) heptanoic acid. The molecule has a boomerang shape, as befitting its country of origin, which is well illustrated in the Fourier projection down the axis shown in Fig. 3. This stereochemistry with the bend at the *cis* substituted ring is analogous to that found in the crystal structure of the synthetic DL *cis* 11-12 methylene octadecanoic acid[6] (Fig. 2), and quite different from the straight chain structure of the DL *trans* 9-10 methylene octadecanoic acid[5] (Fig. 1). A chemical synthesis of this molecule, using the methods devised for the C_{19} acids, is now in progress (Hofmann, K., unpublished work).

If Nunn's *cyclo*propene structure for sterculic acid[8] is accepted, as against the 'conjugated structure' or the 'methylene allene' structure, as generally it appears to be[15,16], malvalic acid can now be assigned the structure (I), on the basis of the chemical and spectroscopic evidence[13,14] and our structure analysis of the dihydro derivative.



$$CH_3-(CH_2)_7-C=C-(CH_2)_6COOH \qquad (I)$$
$$\underset{H_2}{C}$$

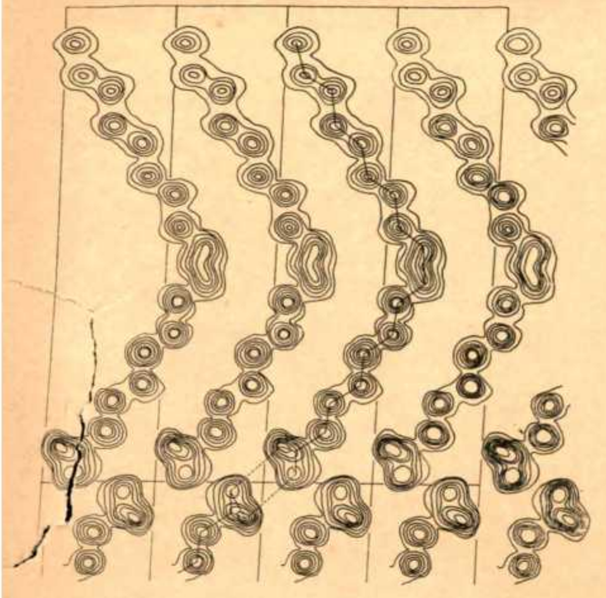


Fig. 3. Dihydromalvalic acid (DL *cis* 8-9 methylene heptadecanoic acid)

This confirmation of the natural occurrence of a C_{18} *cyclo*pentene fatty acid is of interest from the point of view of biosynthesis, since it appears to eliminate a mechanism analogous to the addition of a C_1 fragment to a naturally occurring unsaturated acid as has been proposed in the case of lactobacillic acid[17].

This research is supported by a grant (*E*-1423) from the U.S. Public Health Service, National Institutes of Health. We are grateful to Dr. Vickery, of the Commonwealth Scientific and Industrial Research Organization, Australia, for providing us with the sample of dihydromalvalic acid, and to Prof. K. Hofmann, of the Biochemistry Department of the University of Pittsburgh Medical School, for his close co-operation in our study of these acids.

BIOCHEMISTRY and PHYSIOLOGY

Polysaccharide Fibres in Mammalian Connective Tissue

The presence of fibres which differ chemically and physically from the contiguous collagen and elastin in mammalian and other connective tissue has been reported previously[1]. Four types of fibres were defined upon the basis of morphological variations as observed with the optical microscope and described as redimiculous, vitreous, jointed and barbed[2]. None of these exhibits hydrothermal contraction associated with collagen, and they all resist acid hydrolysis and digestion by collagenase and elastase. Mechanical deformation of individual fibres produces sharp fractures with the vitreous, jointed and barbed types, while the redimiculous variety exhibits predominantly plastic distortion. The absence of the elastic recovery associated with normal protein fibres of connective tissue, added to the other differences, indicates a molecular structure completely different from that of the fibrous proteins.

Morphologically, the redimiculous fibres are similar to cotton fibres in that they consist of helically disposed fibrils with the helix angles changing along the fibre axis as the ends taper. They have approximately the same birefringence as raw cotton and exhibit the characteristic ability to produce this at all angles to the polarized beam. The vitreous fibres show similar birefringence, but no helical fibril assemblies have been observed and there are marked differences in fibre diameters between them. They also exhibit extinction in the usual uniaxial manner. All four types show a sporadic distribution in tissue and areas of local concentration occur adjacent to zones predominantly protein, that is, collagenous. The numbers of the types present decrease in the order redimiculous–vitreous–jointed–barbed. They have not been definitely associated with any pathological changes as yet and the only correlation reported is a general increase in numbers with the age of the tissue[3].

The specimens studied have all been removed from either fresh or fixed tissue by needles, washed in distilled water, and then observed in both normal and polarized light. Recent work by Cruise and Keech (to be published shortly) has shown that when these individual fibres are ground in a conventional tissue grinder and the suspensions are examined with the electron microscope, no evidence of the 640 A. striations associated with collagen is obtained. Each of the four types produced angular quasi-crystalline units dispersed among plastic fibrous debris, suggesting that these fibres are essentially two-phase structures.

Hall *et al.*[4] have reported that a complicated acid, alkali and enzymatic digestion of bovine dermis results in a fibrous residue of what they term 'mammalian cellulose', which gives an X-ray diffraction diagram similar to that from partially oriented cotton fibres. In view of the known resistance of these polysaccharide fibres to the reagents used, it would appear that this treatment has in effect concentrated these fibres from a random distribution in the fresh dermis to a residual mass. These workers have described two types of fibres appearing in the tissue and the residue, one of which they term anisotropic, and which corresponds morphologically with the redimiculous fibres, and the other which they term

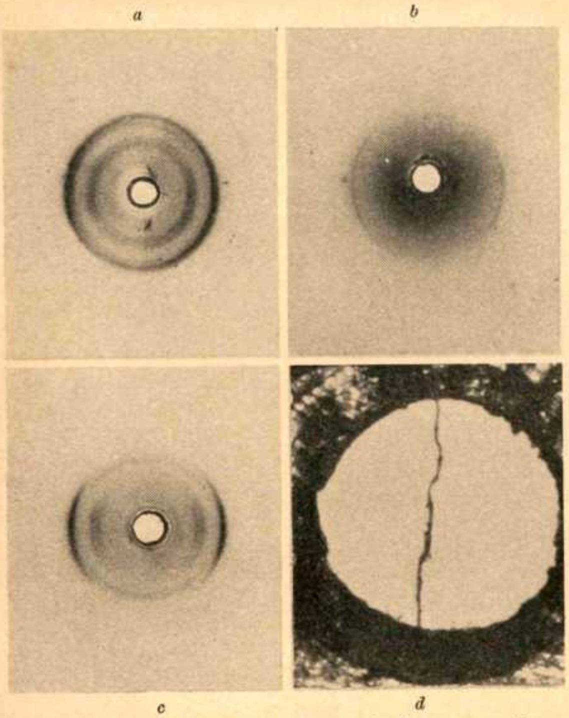

Fig. 1. *a*, *b*, and *c* are enlargements of micro-camera X-ray photographs of: *a*, a somewhat disordered bundle of redimiculous fibres running roughly parallel to the long side of the photograph; *b*, a single redimiculous fibre; *c*, a parallel bundle of cotton fibres: *d* is a photomicrograph of the specimen used for *b*, which was fastened across a hole in copper foil (actual diameter, 0·86 mm.)

a two-phase structure. This appears to be identical with a vitreous type described by Cruise[3] from human Achilles tendon. They suggest that this type is probably composed of a collagen core upon which has been deposited *in vivo* a cellulose coating. In view of the electron microscope disintegration studies of Cruise and Keech this seems doubtful, as no evidence of collagen-like constituents was observed when individual fibres were examined. With this exception there are obvious similarities between the various morphological and optical findings, and attempts were made to obtain X-ray diffraction diagrams from individual fibres to investigate their molecular structure.

Fibres were teased from tissue under the optical microscope and after identification were collected into 'typed bundles' of 5–20 fibres. These and some single fibres were mounted across 1-mm. holes in metal strips and photographed with copper $K\alpha$ radiation from an Ehrenberg–Spear fine focus X-ray tube running at 50 kV., 2 m.amp. and modified to give a focus of 1·0 mm. × 0·1 mm. Diffraction patterns were photographed with a cylindrical camera of 1·0 cm. radius.

Fig. 1 shows some of the photographs: (*a*) of a somewhat disordered bundle of animal redimiculous fibres running roughly parallel to the long side of the photograph; (*b*) of a single human redimiculous fibre; (*c*) is a photograph of a bundle of cotton fibres for comparison; (*d*) is a photomicrograph of the single fibre. The resemblance to native cellulose is very striking, and confirms that the fibres photographed by Hall *et al.*[4] had not been altered by the somewhat drastic treatment used for concentrating them and that these fibres are essentially the same in both human and animal tissue.

A bundle of vitreous fibres gave much the same photograph as (*a*); but so far no diffraction pattern has been detected from a single vitreous fibre.

A bundle of well-aligned jointed fibres, with an exposure four times that of (*a*), gave only faint indications of a diffraction pattern, having some resemblance to that of collagen, but none to cellulose. So far no photographs have been taken of barbed fibres. The investigation is continuing.

Incorporation of Radioactive Iron into Hæmatin a

THE rate of synthesis of hæmoproteins has been studied by measuring their incorporation of iron-59. Most of these studies have concerned hæmoglobin, but some[1,2] also myoglobin, catalase, cytochrome *c* and cytochrome b_5. No report on the incorporation of iron-59 into cytochrome oxidase has yet appeared. Except for cytochrome *c* and cytochrome oxidase, the above pigments all contain protohæm, so that measurement of their individual uptake of iron-59 requires their previous separation, which is often difficult.

In the present work, the fact that cytochrome oxidase (cytochromes $a_3 + a$) has a unique prosthetic group (hæm *a*) which we can readily separate from protohæm, facilitated the study of the synthesis of this enzyme in heart, liver and kidney of rats. Preliminary work had been carried out by D. B. Morell and A. Basser at the Institute of Medical Research of the Royal North Shore Hospital, Sydney (unpublished work), who found some evidence for a greater uptake of iron-59 in hæm *a* of liver than in that of heart. The work of Gallagher, Judah and Rees[3], who studied the effect of copper deficiency in rats, also indicated that hæm *a* was rapidly synthesized in the liver.

Rawlinson and Hale's method[4] for separation of hæmin *a* and protohæmin was improved and incorporated in a method of isolation which gives hæmin *a* usually containing less than 10 per cent of admixed protohæmin in a yield of 80–90 per cent of that present in the first extract from the tissues; protohæmin free from hæmin *a* is obtained in approximately 50 per cent yield.

The freshly excised organs were squeezed thoroughly in heparinized saline so as to remove as much blood as possible, and washed with saline. Homogenates prepared in homogenizers of the Potter–Elvehjem type were washed twice with 0·2 *M* sodium acetate buffer of *p*H 5·2 to remove hæmoglobin and myoglobin. The residue was treated with a solution containing 2 ml. of *n*-butanol per 30 ml. of water for 10 min. at 45° C. and finally washed twice with 80 per cent aqueous acetone (v/v).

The hæmins were extracted by 80 per cent acetone containing 0·7 per cent (w/v) of hydrochloric acid, using 50 ml. for the hearts, 100 ml. for the kidneys, and 300 ml. for the livers of 10 rats. The hæmins were brought into ether with dilute hydrochloric acid and the ether solutions washed three times with the dilute acid, adding some ferrous sulphate during the second washing. The hæmins were then separated by distribution between pyridine – ether and aqueous hydrochloric acid – pyridine according to Rawlinson and Hale's method, except that the ether phase was repeatedly washed with large amounts of the aqueous phase until the absorption band of protohæmochrome had disappeared, leaving hæmin *a* of 90–95 per cent purity. The hæmins of the first two aqueous extracts, almost pure protohæmin, were brought back into ether with 10 per cent hydrochloric acid.

Blood was collected by heart puncture, and an ether solution of its protohæmin prepared from it. Ferritin was isolated in rather low yield from a portion of the liver homogenate as described by Theorell *et al.*[1] and its iron determined by Trinder's method[5].

The hæmins were extracted from their ether solutions with 0·1 *N* sodium hydroxide and measured spectrophotometrically as hæmochromes in 20 per cent pyridine – 0·1 *N* sodium hydroxide – sodium dithionite, applying the formula of Lemberg *et al.*[6]. Hæmin iron was calculated by assuming a molecular weight of 652 for protohæmin and 870 for hæmin *a*.

Radioactivity was counted in an annular well scintillation counter and corrected, for decay, to the day of injection. The total isolation procedure could be carried out in three days.

Ten rats weighing about 150 gm. each were used for each experiment. Each rat received intraperitoneally about 2 μc. labelled ferric ammonium citrate containing 5–10 μgm. of iron and giving a count of 102,000 per min.

Table 1

	Counts/min. per 10 rats with standard deviations* after		Specific activities (counts/min./μgm. iron) after :	
	7 days	14 days	7 days	14 days
Blood†	337,000 ± 2,100	389,000 ± 1,000		
Protohæmin				
Heart	50 ± 3·5	62 ± 4	8·7	6·9
Kidney	280 ± 12	131 ± 10	8·4	8·4
Liver	1,180 ± 46	2,050 ± 46	8·2	8·2
Blood	—	—	8·8	8·1
Hæmin *a*‡				
Heart	24 ± 2·5	26 ± 3	4·5	3·9
Kidney	104 ± 6	92 ± 4	9·6	9·8
Liver	212 ± 10	280 ± 20	12·9	12·5
Liver/ ferritin§	33,600 ± 600	12,700 ± 370	12·9	6·0

* Standard deviations apply only to the counting procedure.

† Assuming the blood volume of the rat to be 10·0 ml.

‡ Specific activities corrected for protohæmin content which was as follows : after 7 days, heart 6, kidney 7, liver 10 per cent ; after 14 days, heart 0, kidney 1, liver 27 per cent.

§ Isolation incomplete.

As expected, most of the radioactive iron is found in the ferritin and hæmoglobin. The specific activities, however, of the hæmins isolated from the organs are similar to those of hæmoglobin–protohæmin. There are no significant differences of blood protohæmin and the protohæmin from the organs, with the possible exception of the heart. A substantial and variable part of the protohæmin isolated from the organs is, however, derived from hæmoglobin and myoglobin, which our procedure failed to remove completely, and not from cytochromes of type *b*.

The specific activity of hæmin *a* proves that iron is rapidly incorporated into the cytochromes of type *a*. A comparison of the specific activities of protohæmin and hæmin *a* shows that the incorporation into hæm *a* exceeds that into protohæm in the kidney and especially in the liver, whereas in the heart the hæm *a* activity is distinctly smaller. These findings agree with the observations of Gallagher, Judah and Rees[3] that cytochrome oxidase and hæmin *a* rapidly decrease in copper deficiency and are rapidly restored by copper, and that the decrease is more marked in the liver than in the kidney. Their experiments differ, however, from ours in that a physiologically abnormal deficiency of hæm *a* was present which may have provided an extra stimulus for hæm *a* synthesis.

The differences between the one- and two-week experiments are scarcely significant, except that the total activity in hæmoglobin has risen, and the specific activity in liver ferritin has decreased, as expected. Experiments will be carried out with shorter times of incubation to obtain more information on the rates of incorporation of iron. It will also be of interest to see whether hæm *a* is synthesized *in vitro* by liver homogenates, as Minakami, Yoneyama and Yoshikawa[7] have recently reported for cytochrome *b*.

We are indebted to Prof. C. Rimington for allowing this work to be carried out in his Department, and for his help in the animal experiments, to Miss E. M. Clarkson for the estimation of the iron content of the ferritin preparations, and to the Australian National Health and Medical Research Council for a travel grant.

Rate of Exchange of Phosphate in Red Blood Cells : Effect of Thyroid Hormones

A METHOD for the *in vivo* determination of the rate of exchange of phosphate in red blood cells by means of the s^{32}P coefficient has already been described. This coefficient measures the outflow of phosphorus-32 from circulating labelled red blood cells[1]. It has been shown that s^{32}P represents the turnover-rate of acid-soluble phosphate in the red blood cell[2].

The exchange-rate of phosphorus-32 has been studied by means of this technique in man and rat under different conditions of thyroid activity.

In euthyroid men, the mean value of s^{32}P for 170 determinations is $4 \cdot 4 \pm 0 \cdot 3 \times 10^{-4}$/min. Hyperthyroidism (32 cases) and hypothyroidism (23 cases) are characterized by s^{32}P coefficients of $5 \cdot 3 \pm 0 \cdot 4$ and $3 \cdot 3 \pm 0 \cdot 4 \times 10^{-4}$/min. respectively.

In the rat, the mean value of 7·0 ± 0·5 × 10^{-4}/min. in 20 controls reaches 7·9 ± 0·4 (17 animals) after treatment with thyroid extract for 30 days and decreases to 5·7 ± 0·5 (20 animals) after continuous administration of methyl-mercapto-imidazol for the same period of time. In these various conditions there was no significant modification of the soluble phosphate concentration of the red blood cells. It was possible to establish a high correlation between the variations of the s^{32}P coefficient and the basal oxygen consumption measurements.

These findings imply a close relationship between thyroid activity and the turnover-rate of acid-soluble phosphate in the red blood cells. From preliminary *in vitro* experiments, it seems that the thyroid hormone acts directly on phosphate transfer: *in vitro* addition of *l*-triiodothyronine (5 μgm. per cent) to labelled red blood cells, incubated in non-radioactive plasma of myxœdematous patients, is followed by an increase of the outflow-rate of phosphorus-32.

Enzymatic N-Methylation of Histamine

The *in vivo* studies of Schayer[1] have shown ring N-methylation to be the principal pathway of histamine metabolism in a variety of mammalian species. His work demonstrates the following scheme:

histamine ⟶ 1-methyl-(β-aminoethyl) imidazole
(methylhistamine)
⟶ 1-methylimidazole-4-acetic acid

Kobayashi[2] found that incubation of histamine with whole-liver homogenates resulted in the formation of 1-methylimidazole-4-acetic acid. These observations reflect the summation of at least three enzymatic processes, one of which is concerned with the synthesis of a co-factor needed for histamine methylation. This report describes the isolation and properties of an enzyme, imidazole N-methyl transferase, which catalyses the ring-N-methylation of histamine requiring S-adenosylmethionine as the methyl donor.

The enzyme was purified approximately eight-fold in two steps from the soluble supernatant fraction of mouse liver. After homogenization of mouse liver with 4 vol. of isotonic sucrose and centrifugation at 78,000*g*, the supernatant fraction was adjusted to *p*H 5·0 with dilute acetic acid and heated for 5 min. at 50° C. After centrifugation, the precipitate was discarded and the supernatant fluid fractionated with ammonium sulphate. The protein fraction precipitated between 50 and 70 per cent saturation was centrifuged, dissolved in 0·01 *M* phosphate buffer *p*H 7·4 and dialysed against 0·001 *M* phosphate buffer *p*H 7·4 overnight. The partly purified enzyme can be stored frozen for several weeks at – 10° C. without loss of activity.

Enzymatically formed methylhistamine was extracted with chloroform at alkaline *p*H[3]. Under these conditions, 88 per cent of the methylhistamine, but only 7 per cent of the histamine, are extracted into the chloroform.

Table 1 shows the absolute requirement by the purified enzyme for S-adenosylmethionine. Magnesium ions and reduced glutathione are not necessary in this system. Furthermore, dialysis of the enzyme against versene or the addition of versene to the reaction mixture does not alter the enzymatic activity. This indicates that imidazole-N-methyl transferase differs from catechol-O-methyl transferase[4]. Enzymatic activity is not altered by pretreatment of animals with 'Marsilid', a monoamine oxidase inhibitor which blocks the conversion of methylhistamine to 1-methylimidazole-4-acetic acid[3].

Table 1. Requirements for Ring-N-Methylation of Histamine by Purified Mouse Liver Enzyme

Reaction mixture*	Methylhistamine formed (μmoles)
Whole system	0·041
Whole system + 2 mgm. reduced glutathione	0·043
Omit magnesium chloride	0·044
Omit S-adenosylmethionine	0·000
Preheated enzyme	0·000

* Reaction mixture containing 2 ml. 0·1 *M* phosphate buffer *p*H 7·4, 0·5 ml. purified mouse-liver enzyme (0·22 mgm. protein), 0·4 μmoles S-adenosylmethionine, 20 μmoles magnesium chloride, 0·05 μmoles histamine dihydrochloride labelled with carbon-14 (Nuclear Chicago) (12,500 c.p.m.), in a final volume of 3·0 ml. was incubated at 37° C. for 4 hr.

The reaction mixture was saturated with sodium sulphate after the addition of 0·5 ml. of 5 *N* sodium hydroxide and the methylhistamine extracted with 15 ml. chloroform. An aliquot of chloroform was evaporated to dryness, the residue eluted with 0·5 ml. of hyamine (ref. 8) and phosphor and counted in a 'Tri Carb' liquid scintillation counter.

The enzymatic product was proved to be methylhistamine by three techniques. After cochromatography in ethanol/0·1 *N* hydrochloric acid (95 : 5) of the enzymatic product and synthetic methylhistamine[3], a radioautograph demonstrated a single spot which exactly coincided in R_F and shape with the ninhydrin-stained area. The specific activity remained constant after four recrystallizations as the dipicrate[5] with added carrier. Finally, incubation with mouse liver homogenate formed radioactive 1-methylimidazole-4-acetic acid. This was proved as follows: Enzymatically formed methylhistamine was incubated with whole mouse liver homogenate for 4 hr. The mixture was boiled, filtered and passed through a 'Dowex-1'-acetate 100–200 mesh column (10 cm. × 1 cm.). The column was washed and then eluted with 0·5 *N* acetic acid. After concentration of the eluate, it was recrystallized from acetone/water with carrier 1-methylimidazole-4-acetic acid (synthesized from cyanomethylimidazole[6] by Pyman's method[7]). There was no decrease in specific activity after four recrystallizations while carrier imidazole acetic acid could readily be freed of radioactivity by this technique.

Imidazole-N-methyl transferase has been found to be present in most tissues of all species studied so far, and appears to be of paramount importance in histamine metabolism. A more detailed study of this enzyme will be the subject of a future communication.

Inactivation of Isoniazid by Peroxidase

INVESTIGATIONS on enzymes of *Mycobacteria* reported from this laboratory[1] and elsewhere[2,3] have shown the importance of cellular peroxidase for the activity of isoniazid. Results of an extension of these studies bearing on the effect of peroxidase on the tuberculostatic activity of isoniazid form the basis of the present communication.

Using *Mycobacterium tuberculosis H37Rv* as the test organism, growth studies were carried out on Youman's medium (without serum) and the observations were made usually at the end of three weeks incubation at 37° C. Horse-radish peroxidase (obtained through the courtesy of Dr. E. F. Hartree, Molteno Institute of Biology and Parasitology, Cambridge), beef-liver catalase (Boehringer) and mammalian cytochrome *c* (Boehringer) were sterilized by Seitz filtration, whereas hæmin (Roche), hæmoglobin (Difco) and isoniazid (Roche) were autoclaved; 0·05 c.c. of the test organism, grown for 10 days on Dubos 'Tween' albumin medium, was used as the inoculum per tube.

Table 1. EFFECT OF PEROXIDASE AND RELATED COMPOUNDS ON GROWTH-INHIBITION OF *Mycobacterium tuberculosis H37Rv* BY ISONIAZID

Supplement	Conc. γ/c.c.	Isoniazid (γ/c.c.)							
		0	0·05	0·1	0·5	1	5	10	25

Hæmoglobin	10	+	+	−	−	−	−	−	−
Cytochrome *c*	10	+	+	−	−	−	−	−	−

+, growth; −, no growth.

The mean results of several experiments are summarized in Table 1. Fisher[4] first demonstrated, later confirmed by Knox[5], that hæmin strongly antagonized isoniazid. It was further shown that it breaks up isoniazid to di*iso*-nicotinoyl-hydrazine and *iso*-nicotinic acid[6,7]. In the present study, it is seen that while on a weight basis peroxidase is 100 times as active as free hæmin, on the basis of its hæmin content, which is 2·5 per cent, it is 4,000 times more active. The fact that inactivated (autoclaved) peroxidase showed no effect indicates that the reaction is enzymatic and specific, since the other hæm-proteins were without activity.

These experiments were carried out with extracellular peroxidase. Isoniazid-susceptible tubercle bacilli have, however, the peroxidase at the surface and intracellular. Thus, isoniazid could be fixed to the bacteria and broken down within the cell. If the breakdown products are liberated outside by extracellular peroxidase, they may not enter the bacterial cell.

Much work has been done on the possible modes of the action of isoniazid. Investigations of our own demonstrated that isoniazid does not act by inhibition of either catalase or peroxidase[8], and we proposed a mechanism by which isoniazid is fixed to susceptible cells and metabolized with a peroxidase–oxidase system[9] similar to that of tryptophan proposed by Knox and Mehler[10].

That the activity of isoniazid may be due to its breakdown to peroxide is not supported by the fact that the more peroxide-susceptible, catalase-negative mutants are, on the contrary, resistant to the drug. Further, the action of peroxidase is also not merely due to its removal of peroxide, since otherwise catalase should have been equally effective.

These studies emphasize that the breakdown products of isoniazid, other than peroxide, eventually exert the inhibitory effect by blocking an essential function once they are transported across the cell membrane into the cell.

Quantitative Estimation of Purines by the Visual Scanning of Photographs of Paper Chromatograms

ESTIMATION of microquantities of purines by paper chromatography was first suggested by Hotchkiss[1]. Later, detection by photographing with an ultraviolet source has amplified the method[2]. Tennent *et al.*[3] and others have designed adaptors for the Beckman spectrophotometer to enable direct estimation of the purines from paper chromatograms. This method requires costly instrumentation, and is time-consuming unless an automatic recorder is provided. Other authors have estimated the size of the spot[4] produced on the photograph.

To obtain a quantitative relationship between area and concentration it is necessary that a spot of accurate dimensions be placed on the starting line. This is frequently difficult. We have been able to produce quantitative results by the scanning of photographs on an automatically recording (visual) densitometer designed by us and reported in detail in a subsequent paper. The densitometer has a high sensitivity, which enables density as well as area definition to be recorded.

Fig. 1, showing typical calibration curves of adenine and adenosine, was obtained by the following method. The standards 0·02, 0·04 and 0·08 μmole of the substance were spotted on to Whatman No. 1 paper. The three concentrations were developed on the same paper with *iso*-propyl ether, 90 per cent (w/v) formic acid, (3 : 2)[5] for 6 hr. by the ascending technique. The papers were then dried and photographed by contact photography on to 'Kodagraph' contact paper (extra thin) using a B.G.E. germicidal lamp to produce the image[6]. The print was slightly overexposed to ensure an even black background.

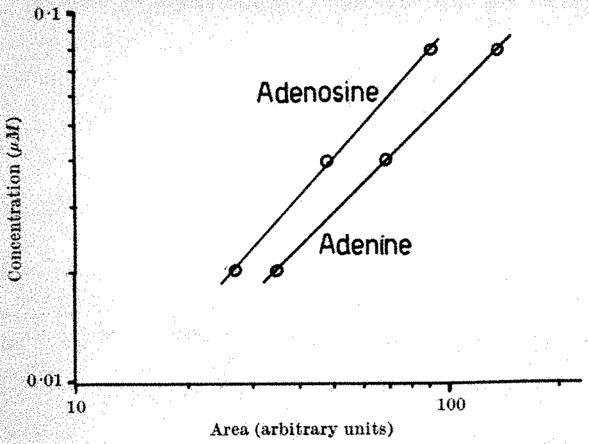

Fig. 1

The print was then developed, fixed and dried in the usual way. The print was cut in 2-in. strips and scanned. The record produced gave a tracing of the absorption of the spot. The area under the curve was estimated with an 'Allbrite' planimeter, and this area was plotted on a double logarithmic graph against the concentration of the purine. The resulting plot gave a linear calibration. It was found that the base-line obtained on such a curve was more stable than that obtained by scanning a blank filter paper. The method is also applicable to other substances, such as steroids[7], which have absorption properties in the ultra-violet regions.

Detection of Gentiobiose and Sophorose in Cultures of Certain Micro-organisms growing in Defined Glucose-containing Media

THE ability of cellulose-forming species of *Acetobacter* to produce from glucose a mixture of melibiose, cellobiose, cellotriose, cellotetraose and fructose, together with higher oligosaccharides some of which yield fructose on hydrolysis, has been reported in recent communications[1-3]. We have now examined the behaviour, in comparable conditions, of *Acetobacter aceti* N.C.I.B. 8554, *Acetobacter rancens* N.C.I.B. 7214, *Acetobacter acidum-mucosum* N.C.I.B. 8133, and *Acetobacter acetosum* var. *nairobiense* N.C.I.B. 7212, none of which produces cellulose. *A. aceti* was grown in a medium containing (gm./l.): $(NH_4)_2SO_4$, 3; $MgSO_4.7H_2O$, 2; KH_2PO_4, 3; glucose, 30. The same ingredients with addition (gm./l.) of: DL-alanine, 0·1; asparagine, 0·1; calcium D-pantothenate, 0·002; riboflavin, 0·002 and biotin, 0·0003, were employed to make up the medium for the three other species. These media were dispensed in volumes of 200 ml. in sixteen Glaxo flasks, four flasks for each species. After inoculation and incubation for 10 days at 28° C. the contents of each set of four flasks were Seitz-filtered and concentrated to about 50 ml. in presence of a little barium carbonate *in vacuo* at 35°. Each concentrate was filtered and treated in the following manner in all four cases. It was added to a column (4·5 cm. diameter) filled with a charcoal–'Celite' (50 : 50, w/w) mixture. The column was eluted with water (5 l.) and then with aqueous ethanol solutions containing, respectively, 5, 15, 20 and 35 per cent (v/v) of ethanol. The aqueous ethanolic eluates were combined (4 l.), concentrated under low pressure at 35° C. to 500 ml. and treated successively with 'Zeo-Karb 225' (H^+ form) and 'De-Acidite *E*' (OH^- form).

After removal of these resins the solution was concentrated further to a syrup and examined in three ways by paper chromatography using: (*a*) *n*-propanol–water–ethyl acetate, 7 : 2 : 1 by vol.; (*b*) pyridine–water–ethyl acetate, 1 : 2 : 2 by vol.; and (*c*) the method of Bayly and Bourne[4], in which comparison is made of the benzylamine derivatives of sugars.

The chromatographic pattern afforded by the products of each species of *Acetobacter* was the same in all cases. Two disaccharides and one higher oligosaccharide predominated in each culture, and these disaccharides showed the mobilities of gentiobiose and sophorose, respectively, when run against authentic disaccharides by procedures *a*, *b* and *c*.

A. rancens was now employed in an experiment with 30 l. of medium. After incubation the metabolism solution was concentrated in presence of barium carbonate *in vacuo* at 35° C., filtered and subjected to charcoal–'Celite' treatment. The aqueous ethanolic eluates were combined, concentrated *in vacuo* at 35° C., desalted in the manner described by Walker and Wright[2] and oligosaccharides left in solution were separated by gradient elution from charcoal, following the technique of Bacon and Bell[5]. 95 fractions, each of 200 ml., were collected. From fractions 15–60 two reducing sugars were isolated, purified by band paper chromatography and examined in the solvents of *a*, *b* and *c*, in which they were indistinguishable from gentiobiose and sophorose, respectively. Also, on hydrolysis each yielded solely glucose, and on acetylation each yielded an acetate which on combustion gave values corresponding to $C_{28}H_{38}O_{19}$, the empirical formula for a disaccharide octa-acetate. Final confirmation of identity was obtained in each case by paper ionophoresis in borate buffer *p*H 10 at 800 V. for 3 hr.

In a study of glucose metabolism in *Aspergillus nidulans* Eidam, the mould was grown as surface cultures on a solution which contained (gm./l.): NH_4NO_3, 3·00; K_2SO_4, 0·22; $NaH_2PO_4.2H_2O$, 7·30; $MgSO_4.7H_2O$, 5·00; $FeCl_3.6H_2O$, 0·16; $ZnSO_4.7H_2O$, 0·05 and glucose, 100.

After 8 days at 26° the metabolism solution (20 l.) was filtered and concentrated in presence of a little barium carbonate at 35° to a thin syrup. This was subjected to charcoal–'Celite' chromatography to eliminate hexoses, as described by Bacon[6]. After removal of ethanol-insoluble salts of phosphoric acid esters[2] the oligosaccharide fraction was desalted with 'Zeo-Karb 225' and 'De-Acidite *E*', concentrated at

35°, and subjected to gradient elution with water and with aqueous ethanol from a charcoal–'Celite' column[7]. 96 fractions, each of 100 ml., were collected and contained three disaccharides and three higher oligosaccharides. Fractions 27–40, which contained principally disaccharides, were combined, evaporated to low bulk and resolved by cellulose column chromatography into three fractions containing two main components and a third component in traces. By band paper chromatography these two main components were isolated in pure condition. Each yielded only glucose on hydrolysis and each gave an acetate, $C_{28}H_{38}O_{19}$. By chromatographic procedures similar to those used for the products of the *Acetobacter* species and by ionophoresis in borate buffer *p*H 10 at 900 V. for 3 hr., the two disaccharides were shown to be gentiobiose and sophorose.

These results are of interest in relation to questions concerning cellulose synthesis by *A. acetigenum* and the formation of β-linked glucosaccharides by moulds. It is intended to report the work in more detail elsewhere.

For gifts of specimens of rare sugars we are indebted to Dr. J. S. D. Bacon, Prof. K. Freudenberg, Dr. L. Hough, Prof. S. Peat, Dr. Elizabeth Percival and Dr. W. J. Whelan, and we are grateful to Dr. S. A. Barker, who carried out for us an ionophoretic identification.

Malonate Metabolism by Plant Tissues

INTEREST in malonic acid has been largely directed towards its role as a competitive inhibitor of succinic dehydrogenase. Very little attention has been directed towards the occurrence of malonic acid in plant tissues or toward the metabolism of malonic acid *per se*. In 1952 Bentley[1] showed malonate to be present in about eighteen species of leguminous plants. Malonic acid has also been reported in species from families other than the legume family[1-3]. That malonic acid could be metabolized was established more than thirty years ago when it was shown that malonate could serve as the sole carbon source for certain bacteria[4]. More recent work established that malonate was readily metabolized by enzyme preparations from fungi[5,6], mammals[7,8], and plants[9,10]. The present communication reports a wide range of higher plants which possess the ability to metabolize malonate.

The procedure involved submerging the petiole of excised leaves into a vial containing 60 μmoles 2-^{14}C labelled malonate (specific activity = 1,000 c.p.m./μmole). The leaves were permitted to absorb the labelled malonate for 17 hr., at which time the leaves were oven-dried and the organic acids extracted with hot water. The organic acids were then separated by paper chromatography (ether/acetic acid/water, 4 : 1 : 5) and the individual organic acids counted on a gas-flow counter. The radioactivity in the individual organic acids (except malonate) was summed and the percentage of the total activity contributed by each acid calculated (Table 1). When radioactivity within an individual acid failed to exceed twice background, the percentage of the total count for that acid was listed as 'trace'.

Table 1. PERCENTAGE CONTRIBUTION BY INDIVIDUAL ACIDS TOWARD TOTAL RADIOACTIVITY IN ORGANIC ACID FRACTION OF LEAVES FOLLOWING 17-HR. ABSORPTION PERIOD OF 2-^{14}C MALONATE THROUGH LEAF PETIOLE

* Unidentified acids, usually three or four in number, were situated near the origin and in most cases were poorly resolved.
T, Trace (radioactivity failed to exceed twice background).

Table 1 lists the percentage radioactivity present in individual organic acids following a 17-hr. absorption period of 2-^{14}C malonate through the leaf petiole. The presence of radioactivity in organic acids indicated that malonate was metabolized and that the No. 2 carbon was incorporated into various acids. Comparing the radioactivity among the isolated acids, it may be noted that malate in each case contained the largest percentage of radioactivity, followed in most cases by citrate, succinate, and fumarate, respectively. Substantial quantities of radioactivity were also present in several unidentified acidic constituents possessing quite low R_F values. Identification of these acidic constituents is incomplete.

The fifteen plant species which are listed in Table 1 were selected at random from forty-five species examined. The thirty unlisted species follow: acacia, almond, blackeye pea, bougainvillea, bush bean, cactus, cherimoya, eugenia, feijoa, fuschia, geranium, hydrangea, ivy, loquat, morello cherry, mustard, natal plum, papaya, passion fruit, pear, persimmon, poinsettia, potato, rose, rough lemon, sunflower, trifoliate orange, tropical guava, white sapote, and wing nut. Substantial radioactivity was detected in one or more of the Krebs cycle acids in each species examined.

Working with particulate enzyme preparations, Young and Shannon[10] recently suggested that the pathway of malonate metabolism in bush bean leaves proceeded according to the following scheme:

$$\text{malonate} \longrightarrow \text{malonyl coenzyme } A \longrightarrow \text{acetyl coenzyme } A$$

The product of this reaction scheme, acetyl coenzyme *A*, was then available for condensation with oxalacetate and subsequent oxidation by the Krebs cycle. While only respiratory reactions were investigated, it was suggested that the product, acetyl coenzyme *A*, participated in other reactions as well. Brady[11] reported recently that malonyl coenzyme *A* was an active participant in fatty acid synthesis.

The radioactive assay results indicated that forty-five species, comprising twenty-seven families, incorporated the No. 2 carbon of malonate into one or more of the identified acids—malate, citrate, succinate, or fumarate. In view of the large number and diversity of species performing this incorporation, it is suggested that the enzyme(s) capable of metabolizing malonate may be widespread throughout the plant kingdom.

Micro-volume Drop-plate Assay of Antibiotics

IN assaying antibiotic substances by any of the well-known plate diffusion methods it is necessary to dilute the unknown solution to varying degrees, depending on the original concentration. In addition to minimizing the possible disturbing influence of interfering substances and the *p*H of the original sample in the assay plate, this procedure has the practical convenience of providing inhibitory zones of a suitable size-range needed for a satisfactory assay. However, if one could run good assays on the original concentrated samples without resorting to serial dilution it would simplify the assay procedures. We have found that such a step is possible with the use of a micrometer syringe which would enable one to spot micro-volumes directly on the assay plate with great accuracy. These minute volumes dry rapidly and form discrete spots, giving uniformly circular inhibition zones after allowing proper diffusion and incubation periods.

In order to test the practicability of the outlined approach, several four-point assays were run on liquid samples containing penicillin by both the conventional cup-method and the micro-volume drop-plate method, the latter with the aid of a micrometer syringe ('Agla' brand, Burroughs Wellcome and Co.). In both cases the plates were prepared according to the enriched seed layer method described by the U.S. Food and Drug Administration[1], using 'Difco Penassay' base and seed agars. The assay organism was *Bacillus subtilis* A.T.C.C.6633. In the droplet method, in place of cups, the same volumes of a suitable penicillin *G* standard and the unknown—usually, 0·4 and 1·6 μl., corresponding to two and eight small divisions on the peripheral scale of the micrometer head—were spotted directly on the agar surface. Assay values were calculated from the resulting inhibition zones using Miyamura's nomogram[2].

Results of the assays given in Table 1 show that the droplet method as used by us is quite satisfactory, and the errors involved cannot be considered to be higher than in the commonly used cup, cylinder and bead-modifications of the plate assays. In our experience, the method is simpler than these other conventional plate methods and less time-consuming, as highly concentrated unknowns can be used directly in the assay plate. The method has no material disadvantages except, perhaps, the increased concentration and care required of the operator while adding small volumes represented by one or two small divisions on the peripheral scale of the micrometer head. However, with the addition of a semi-automatic addition mechanism such as the one described earlier[3], this method is capable of being developed into a good routine tool for assaying not only antibiotics but also other compounds which are physiologically active in agar plate methods involving micro-organisms or cell-lines.

Table 1. PENICILLIN TITRES OF UNKNOWNS IN UNITS/ML.

Sample No.	Cup-plate assay	Micro-volume drop-plate assay
1	1,020	1,010
2	2,020	2,000
3	2,180	2,390
4	1,860	1,840
5	1,910	2,050
6	1,740	1,700
7	2,180	1,940
8	1,598	1,557
9	1,650	1,683

Further evaluation of the method is being published in detail elsewhere.

I am indebted to Dr. A. H. Amin, director of research, for the encouragement he has given me in this work. I also wish to acknowledge the technical assistance of colleagues in the microbiological research laboratory.

Incidence of the Erythrocytic Defect associated with Drug-Sensitivity among Oriental Subjects

IN the past few years a new type of metabolic lesion of the red cell has been elucidated. It was found that sensitivity to the hæmolytic action of the 8-aminoquinoline primaquine and many other compounds was due to an intrinsic defect of the red cell[1]. This defect can be demonstrated *in vitro* by: (1) incubating the red cells with a solution of acetylphenylhydrazine and observing the pattern of Heinz body formation[2], and (2) incubating the red cells with acetylphenylhydrazine or a number of other substances and measuring the level of reduced glutathione after an incubation period of 2 hr. (the glutathione stability test)[3], or (3) measuring the activity of the enzyme glucose-6-phosphate dehydrogenase in the red cells[4].

It has been known for some time that sensitivity to drug-induced hæmolysis varies considerably in different racial groups. Application of these *in vitro* techniques has disclosed marked differences in the incidence of this red-cell defect in various population groups. Thus, the defect is common in American Negroes, but rare in most Caucasian populations. It is relatively common in Sardinia, and in Israel has been found to occur commonly in Sefardic, but not in Aschkenazy Jews. As might be expected, the incidence of drug-induced hæmolytic anæmia and favism (which occurs only in individuals with this red-cell defect) is highest in those groups that have a high incidence of the red-cell defect as demonstrated by *in vitro* means. Available data regarding incidence and distribution of this defect, as elucidated by many authors, have been reviewed recently[5].

Several cases of fava bean-[6], 8-aminoquinoline-[5], and naphthalene-induced hæmolytic anæmias[7] in oriental people have been reported in the literature, but the incidence of this red-cell defect in this race has not been determined. For this reason, we have applied the glutathione stability test to 99 subjects of oriental origin, mostly students, all residing in the United States. The test was carried out exactly as described originally by one of us, except that 1 ml. of acid–citrate–dextrose solution was used as anticoagulant per 5 ml. of whole blood. This permits cold storage of blood samples for as long as 3 or 4 weeks before the test is performed[8]. In the studies described here, the test was always performed within 10 days of the time the blood was drawn. In the case of the single positive reactor detected, the test was repeated with a freshly drawn sample of blood, both with heparin and acid–citrate–dextrose solution used as anticoagulant. The test for sensitivity using Heinz bodies was carried out as described previously[2]. The assays for glucose-6-phosphate dehydrogenase and 6-phosphogluconate were carried out by means of a slight modification of the method described by Marks[9].

The results of studies on the stability of glutathione are given in Table 1. The red cells of all subjects tested contained more than 37 mgm. per cent reduced glutathione after incubation with acetylphenylhydrazine except for the one positive Thai subject. His red cells contained 15 mgm. per cent reduced glutathione after incubation with acetylphenylhydrazine. In the case of the positive reactor, an assay for glucose-6-phosphate dehydrogenase showed that only 4·0 units/gm. of hæmoglobin were present, as compared with a mean normal of 15·9 units/gm. of hæmoglobin as reported by Marks[9]. 6-Phosphogluconic dehydrogenase activity was normal. The Heinz body pattern, after incubation with acetylphenylhydrazine, was typical of drug-sensitive red cells.

Table 1. PLACE OF ORIGIN OF ANCESTORS OF 99 ORIENTAL SUBJECTS TESTED

The observations presented here are too limited in scope to allow us to draw any quantitative conclusions about the incidence of this defect in oriental populations. It would seem, however, that while this defect does exist among oriental people, the incidence among at least one group, the Chinese, is low.

The co-operation of Drs. S. Larsh and V. Minnich in obtaining blood samples from Thai subjects and of Dr. W. T. Wong in obtaining samples from Chinese subjects, is greatly appreciated.

Taurine in Human Blood Platelets

Morita and Asada[1] have shown a considerable amount of taurine and other sulphur compounds to be present in the platelets of human blood. We have attempted to determine the level of taurine in platelets and the probable metabolic pathway of its formation.

The suspension of platelets was obtained from the blood of healthy humans. The blood was mixed with 5 per cent solution of ethylenediamine tetraacetic sodium salt (10 : 1), and centrifuged many times. The suspension usually contained 2,000,000–3,000,000 platelets/c.mm. counted by the Rees–Ecker method. The contamination by erythrocytes and leucocytes did not exceed 0·1 per cent. The platelets obtained in this manner showed metabolic activity for more than 10 hr. when their oxygen consumption was investigated in Cartesian divers. In the course of investigation the platelets were suspended in physiological solution with an addition of phosphate buffer *p*H 7·3. For quantitative estimation of taurine, 0·3 ml. of the platelet suspension was cytolysed by quick freezing and thawing followed by incubation with a drop of toluene[2] for 20 min. The cytolysate was passed through a column of 'Zeo-karb 225' in the acid form. In these conditions the resin retains the salts and amino-acids, and the taurine and cysteic acid pass through quantitatively into the filtrate[3]. The filtrate was evaporated to dryness and dissolved in 0·2 ml. of redistilled water. A 15-μl. sample was applied eccentrically on a Whatman No. 1 paper disk, and circular chromatography was run for 15 hr. in water–butanol–acetic acid solvent (5 : 4 : 1). The spots were detected by staining with ninhydrin[4]. The quantitative estimation was performed by extinction measurements of the eluate from paper using a Coleman or Hilger spectrophotometer. The error of this method was found to be ± 3·3 per cent.

For investigation of the formation of taurine in the platelets, the suspensions were incubated with $0{\cdot}02\ M$ solutions of cysteine or cysteic acid for 15 hr. in air or nitrogen atmosphere. After incubation the samples were cytolysed and the taurine was estimated as described above. In each experiment the level of taurine was compared with the content of this compound in the platelets from the same specimen of blood without incubation (blank).

We have examined platelets from the blood of 21 normal persons. We have found that the amount of taurine per platelet varies in different persons between $6{\cdot}2 \times 10^{-8}$ μgm. and $9{\cdot}8 \times 10^{-8}$ μgm.; in most cases it was more than $8{\cdot}0 \times 10^{-8}$ μgm. Recalculated per unit of wet weight, this gives a value of 1·5 mgm. of taurine per gm. of platelets.

In the platelets incubated with cysteic acid we have sometimes found a small increase in the amount of taurine. The amount of cysteic acid in the suspension fluid always decreases during the experiment. After incubation of the platelets with cysteine, an increase of about 20–40 per cent in the taurine content was shown in all experiments. If parallel incubations were carried out of two samples at the same time, one with cysteic acid and the other with cysteine, we always found a greater increase in the amount of taurine in the sample with cysteine. An example of a typical experiment is given in Table 1.

Table 1

Suspension of platelets	Preparation of sample	Results (μgm.)	
		Taurine	Cysteic acid
Blood group O 2,600,000 platelets/c.mm. 1,100 erythrocytes/c.mm. 700 leucocytes/c.mm.	Blank platelets cytolysed and denatured + cysteic acid and cysteine	4·3	68
	Sample I platelets incubated 15 hr. in air with cysteine	6·3	trace
	Sample II platelets incubated 15 hr. in air with cysteic acid	5·0	60

We confirmed the production of taurine in the platelets by using cysteine labelled with sulphur-35. The spot of taurine from platelets was radioactive when the suspension was incubated with labelled cysteine.

These results show that in the blood platelets of normal persons the taurine-level is constant. Taurine is produced in the platelets, and cysteine is a better substrate for its formation than cysteic acid. This fact suggests that the taurine in human platelets is formed from cysteine through cysteine sulphinic acid and hypotaurine. Therefore, the mechanism of taurine formation in human platelets resembles that described by Bergeret *et al.*[5] and Awapara[6] in rats.

Further investigations are in progress.

Detection of Antigens as Specific Precipitates on Paper Electrophoresis Strips

AGAR diffusion[1] has been used for detecting antigens after paper electrophoresis. I have found that a precipitin reaction can be carried out directly on the paper.

After electrophoresis, a strip of paper dried at room temperature is placed in contact with filter paper previously moistened with sufficient antiserum to saturate the applied paper. The papers are left in a closed container for 2–4 hr. The electrophoresis strip is then removed and immersed in 0·9 per cent (w/v) sodium chloride for several minutes if Whatman No. 1 paper is used, or overnight for Whatman No. 3 *MM* paper. Nine further washings of 1 min. each are sufficient to remove excess antiserum. The washed strip is dried and stained with bromphenol blue[2]. Specific precipitates appear as dark blue spots on a light blue background.

The method has been applied to the demonstration of a serum protein antigen after electrophoresis in a veronal–borate buffer and of a polysaccharide from *Mycoplasma mycoides*[3] (Fig. 1). The polysaccharide has been detected after electrophoresis in $0{\cdot}05\ M$ acetate, veronal and borate buffers over the range of *p*H 4–11.

The following points should be noted: (1) Large amounts of antigen may yield spots with white centres due to local antigen excess. (2) Intensity of spot colour may not be proportional to the amount of antigen present. Partially overlapping spots may not be distinguishable. (3) Irreversibly adsorbed protein, present before application of serum, may cause artefacts.

While this work was proceeding, a method of detecting antigens on paper by simultaneous electrophoresis of antigen and serum[4] was published.

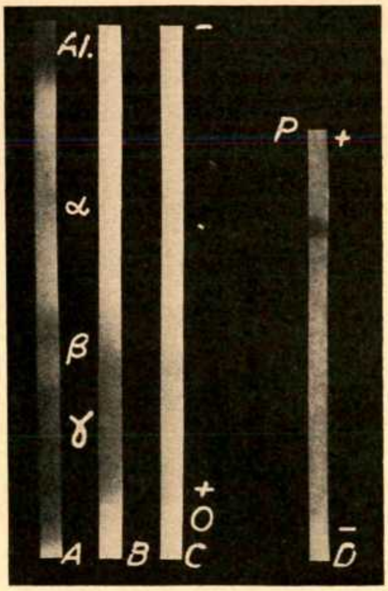

Fig. 1. *A*, *B*, *C*, bovine serum 0·01 ml./5 cm. width paper, applied at origin *O*. Electrophoresis in veronal borate *p*H 8·6. *A*, untreated, stained; *B*, treated with anti-γ-globulin serum, washed and stained; *C*, treated with control serum, washed and stained. *A*1, α, β, γ represent albumin, α-, β- and γ-globulins respectively. *D*, 10 μgm. *M. mycoides* polysaccharide applied at *P*. Electrophoresis in $0{\cdot}05\ M$ borate *p*H 11. Treated with immune serum, washed and stained

Changes in *p*H and Temperature in Poultry Breast Muscles at Slaughter

During a study of factors which might affect the tenderness of poultry meats, some observations were made on the changes in *p*H and temperature occurring in the breast muscle of birds during and after slaughter.

Needle electrodes (Beckman No. 40470) and a thermocouple were tied into the muscle prior to slaughter. The thermocouple was connected to a recorder and the temperature was automatically recorded at ½-min. intervals. *p*H readings were made every 30 sec. during the first 5 min. or so and then at 2- or 5-min. intervals, depending on the rate of fall of the *p*H.

The birds were slaughtered in a manner simulating commercial practice, that is, they were suspended head down and the throat cut. This procedure leads to a rapid bleeding.

Chickens, turkeys and geese were examined.

In all the types of birds examined there was a rise in temperature within 5 min. of the throat being cut, followed by a slow fall. In chickens and turkeys this was most marked, as is shown in Fig. 1, in some cases being as much as 3·5° F. The rise in geese was not as marked and in no case exceeded 1° F. This rise is probably due to continued work by the muscle in the absence of the heat-regulating power of the blood. Chicken and turkey breast muscles are 'white' meats, whereas goose breast muscle is a 'dark' meat. It would appear that there is a definite difference in the temperature reaction of these two types of muscles.

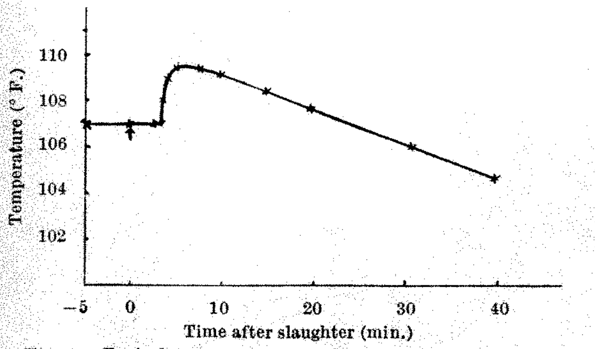

Fig. 1. Typical temperature response of turkey breast muscle after slaughter

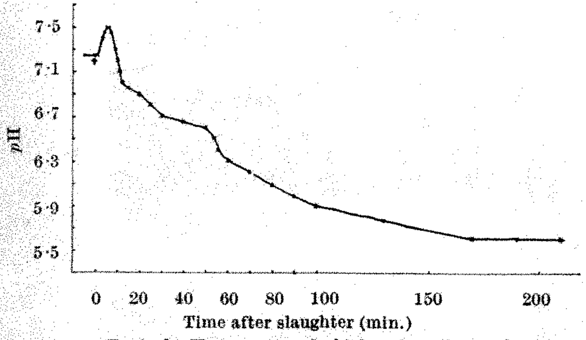

Fig. 2. Typical *p*H response of chicken breast muscle after slaughter

Also, in all the types of poultry examined there was at first a rise in *p*H followed by a gradual stepwise decline as is shown in Fig. 2.

Table 1 gives the mean and range *p*H and temperature rises.

Table 1

Type of bird	No. of birds	Mean *p*H rise	Mean temperature rise (° F.)
Chicken	15	0·20 (0·05–0·30)	1·0 (0·0–2·0)
Turkey	5	0·25 (0·05–0·50)	2·1 (1·00–3·50)
Goose	6	0·15 (0·05–0·25)	0·55 (0·25–0·75)

(Figures in brackets are the range)

Reports by Bate-Smith and Bendall[1] and Scaife[2] on the changes in *p*H occurring in beef and pork muscle after slaughter make no mention of the rise in *p*H that was observed in these studies. This may be due to the initial *p*H being defined (Bate-Smith[1]) as "the *p*H of the muscle within 5 minutes of slaughter". In most cases it was found that the *p*H had already begun to decline 5 min. after slaughter.

A full report of this work will be published elsewhere.

Relaxation of Glycerol-treated Muscle Fibres by Acetone

Certain sulphydryl reagents such as 'Salyrgan'[1] and certain chelating agents such as ethylenediamine tetraacetate[2,3] have been known to have a lengthening action on glycerinated muscle fibres in the presence of adenosine triphosphate. A reasonable explanation of this relaxing action by 'Salyrgan' has already been given[1]. The chelating actions of ethylenediamine tetraacetate and its analogues are of interest. We have reported[4], however, using seven different chelating agents, that their chelating activities were not parallel with their relaxing capacities. Thus the mechanism of these agents remains unsolved.

It was found that acetone had a reversible relaxing action on glycerinated fibres, like ethylenediamine tetraacetate and 'Salyrgan' (Fig. 1). The concentration of acetone required was rather high, but the action was not due to the non-specific effect of high concentration of non-electrolyte, because sucrose and glycerol were quite ineffective in much higher concentration. Acetylacetone and ethyl acetate, especially the latter, were much more effective than acetone, but they were not so complete as acetone in their

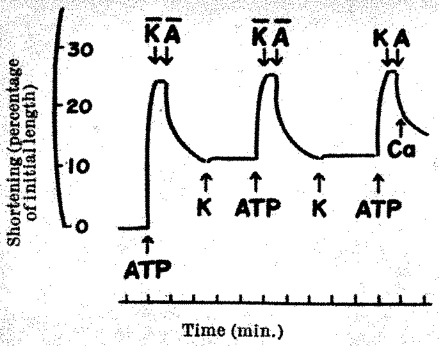

Fig. 1. Extension effect of acetone in the presence of adenosine triphosphate. K, 0·15 M potassium chloride solution containing 0·01 M magnesium chloride and 0·02 M *tris*-(hydroxymethyl)-aminomethane-maleate buffer (pH 6·8); $\overline{K}$, K without magnesium chloride. ATP, 5 mM adenosine triphosphate in K. A, 10 per cent acetone by volume and 5 mM adenosine triphosphate in K. $\overline{A}$, 10 per cent acetone by volume and 5 mM adenosine triphosphate in $\overline{K}$. Ca, calcium chloride added; final concentration, 8 mM

reversibility. Dioxane was also prominent in producing extension, but the fibres lost their contractility completely.

Acetone by itself had little plasticizing action and did not have a significant effect on the adenosine triphosphatase activity of muscle fibres or actomyosin. In the presence of inorganic pyrophosphate or tripolyphosphate, however, acetone exerted a strong relaxing action on fibres without affecting their contractility (Fig. 2). In other words, acetone accelerated remarkably the plasticizing action of pyrophosphate or tripolyphosphate. This suggests that acetone lengthens muscle fibres by enhancing the plasticizing action of adenosine triphosphate.

The effects seem almost the same for ethylenediamine tetraacetate and its analogues as for acetone (Fig. 2). It would be premature, however, to conclude that these facts also explain the mechanism of ethylenediamine tetraacetate relaxation, because the contractility of fibres treated by both ethylenediamine tetraacetate and pyrophosphate was scarcely restored, that is, the relaxation was not reversible. Further studies are needed in this case.

In contrast to these reagents, 'Salyrgan' and p-chloromercuribenzoate showed only a little, if any, accelerating action on the action of pyrophosphate. Granules in skeletal muscle[5,6], which are now accepted as the essential relaxing factor, also did not enhance the plasticizing action of pyrophosphate.

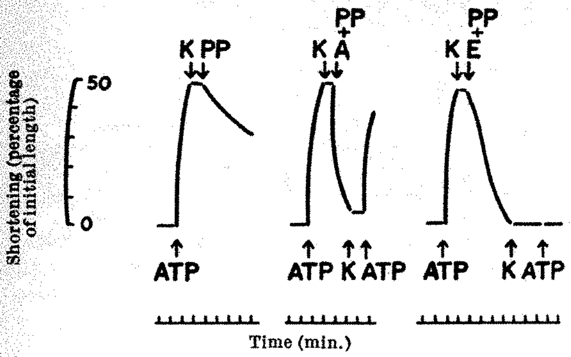

Fig. 2. Acceleration of pyrophosphate action by acetone and ethylenediamine tetraacetate. PP, 1 mM pyrophosphate in K (Fig. 1); $PP+A$, 1 mM pyrophosphate and 10 per cent acetone by volume in K; $PP + E$, 1 mM pyrophosphate and 1 mM ethylenediamine tetraacetate in K; K and ATP, similar to Fig. 1 but at pH 6·6

These observations suggest that there are different kinds of mechanisms for relaxation of glycerol-treated muscle fibres. Further details will be published elsewhere.

We wish to thank Prof. H. Kumagai for his encouragement, and also Dr. S. Watanabe for discussions.

Effect of the Rate of Elimination of Digoxigenin in the Guinea Pig on the Determination of its Lethal Dose

WHEN a drug is given by intravenous infusion it is not possible to define its lethal dose if it is detoxified rapidly, because the apparent lethal dose will depend on the rate of administration of the drug. This difficulty has been emphasized by Beccari[1], who pointed out that in the case of drugs which are rapidly eliminated it is better to define a 'lethal rate' of infusion rather than a lethal dose. The problem of deciding at which rate of infusion to determine the lethal dose has always been apparent in the study of cardiac glycosides, and has been accentuated by the earlier need for biological assay of these drugs. The relationship between rate of infusion and lethal dose of cardiac glycosides and aglycones is complex, depending both on the individual drugs and the species used for the determination of toxicity. In the British Pharmacopœia (1958) and the U.S. Pharmacopœia (thirteenth revision) this problem is defined by laying down maximum and minimum times during which each determination of lethal dose must be made. From Table 1 it can be seen that the apparent lethal dose of digoxigenin determined in the guinea pig depends on the time taken to produce death. At the lower rates of infusion in which the time to produce death is prolonged, the apparent lethal dose has the highest values.

Earlier methods designed to measure the rate of elimination of cardiac glycosides[2,3] did not permit any investigation of the effect of dose on the rate of elimination of these drugs, although it would be expected that the rate of elimination would increase with increasing concentrations of the drug in the

Table 1. LETHAL DOSES OF DIGOXIGENIN IN THE GUINEA PIG

Apparent lethal dose (mgm./kgm.)	Time of infusion (min.)	Rate of infusion (mgm./kgm./min.)	True lethal dose (mgm./kgm.)
9·97	48·6	0·205	5·12
7·78	28·8	0·270	5·13
7·67	26·0	0·295	5·27
5·51	18·0	0·306	4·22
5·28	18·0	0·293	4·10
4·58	16·6	0·276	3·58
Mean 6·80			4·57
Variance 4·10			0·485

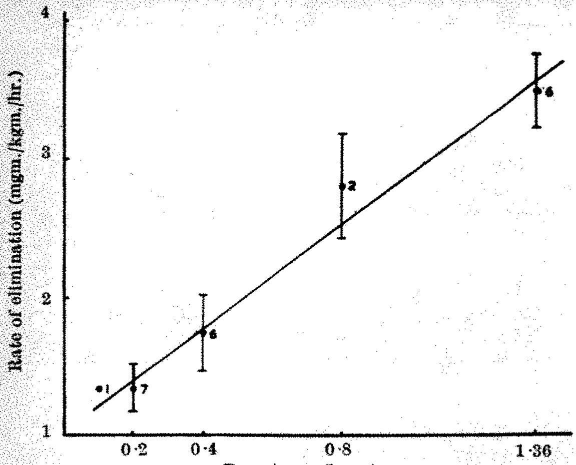

Fig. 1. The relationship between the dose of digoxigenin and its rate of elimination in the guinea pig. The figures beside the points indicate the number of observations at each dose, and the standard errors of these observations are represented by the vertical lines

animal's tissues. By using the method of determining the duration of action of cardiac glycosides described previously[4] it has been possible to establish the relationship between the dose of digoxigenin given and its rate of elimination in the guinea pig. In this method, injections of a suitable dose of adenosine are given regularly at 2-min. intervals. The responses of heart block are recorded on an electrocardiogram, and the duration of each response is measured. After an intravenous injection of digoxigenin the responses to adenosine are at first more prolonged and then gradually this potentiation decreases. The duration of action of digoxigenin is taken as the time during which the responses to adenosine remain potentiated. Fig. 1 shows the effect of increasing dose-levels of digoxigenin upon its rate of elimination by the guinea pig. This graph is based on 22 observations from 12 guinea pigs. The line drawn on the graph is the calculated regression line giving the best fit to the data. Measurements have been made with doses of digoxigenin up to 20 per cent of the dose which kills the guinea pig when infused during 15–30 min., and it is not feasible to administer larger doses in a single injection. The mean rate of elimination of digoxigenin was 1·87 mgm./kgm./hr. per mgm./kgm. For the purpose of the following calculation, it has been assumed that this relationship holds with higher doses of digoxigenin. This figure can then be used in conjunction with experimental results of rates of infusion of digoxigenin and the times to death to calculate the amount of drug actually present in the animal at the time of death, that is, the 'true' lethal dose.

Let D = dose-level actually present in the animal (amount given less the amount eliminated, mgm./kgm.); x = rate of infusion (mgm./kgm./min.); y = rate of elimination (mgm./kgm./min. per mgm./kgm.); = time after start of infusion (min.).

Then:

$$\frac{\mathrm{d}\,(D)}{\mathrm{d}t} = x - yD$$

$$\int \frac{\mathrm{d}\,(D)}{x - yD} = \int \mathrm{d}t$$

$$-\frac{1}{y}\log(x - yD) = t + C \qquad (1)$$

When $t = 0$, $D = 0$, and $C = -\frac{1}{y}\log x$

Substituting in (1) and rearranging:

$$D = \frac{x - \exp(-yt + \log x)}{y}$$

From this formula the 'true' lethal dose of digoxigenin (D) has been calculated for each of the six guinea pigs which received continuous infusions of digoxigenin until death, using the data shown in Table 1. It can be seen that the mean dose of digoxigenin infused into the guinea pig to produce death is about 1½ times the mean amount actually present in the guinea pig at the moment of death. If the scatters of the observations of the apparent lethal dose and of the true lethal dose about their respective means are examined it can be seen that the variance is considerably less when correction has been made for the amount of digoxigenin which has been eliminated during the course of the determination of lethal dose, and this reduction is statistically significant ($F = 8{\cdot}22$, $P < 0{\cdot}05$).

Triiodothyronine in Acute Alcoholic Intoxication

REPORTS in the lay press of the sobering effect of triiodothyronine in intoxicated humans suggested to us the desirability of investigating the effect of this compound on acute alcoholic intoxication under controlled conditions in the laboratory. To this end varying doses of triiodothyronine (3,3′,5-triiodo-L-thyronine as either the free acid or the sodium salt, obtained from Sigma Chemical Co.) were administered intraperitoneally to normal female dogs of 10–15 kgm., after which a dose of 3·0 gm. per kgm. of ethyl alcohol, diluted to 15 per cent with normal saline, was administered intravenously over a period of about 30 min. At the end of 1 hr. after the start of the injection, and afterwards each hour for 7 hr., samples of venous blood were drawn for alcohol analyses[1] and the degree of intoxication assessed according to an arbitrary scale of 10 stages used for many years in this laboratory[2]. Controls were run on each animal, varying only in the absence of the injection of triiodothyronine.

The initial concentration of alcohol in the blood less the concentration at the end of the experiment, divided by the time-interval, gave the rate of disappearance of alcohol from the blood-stream, expressed in mgm. per 100 ml. per hr., which is a reliable index of the rate of alcohol metabolism. The degree of intoxication plotted against the concentration of blood alcohol yielded a curve that made it possible by interpolation to estimate the degree of intoxication at each decrement of 20 mgm. per 100 ml. This device enabled us to average the degree of intoxication at a given blood alcohol-level for a group of dogs.

Two groups of dogs were used, with some of the animals common to the two groups. All had been

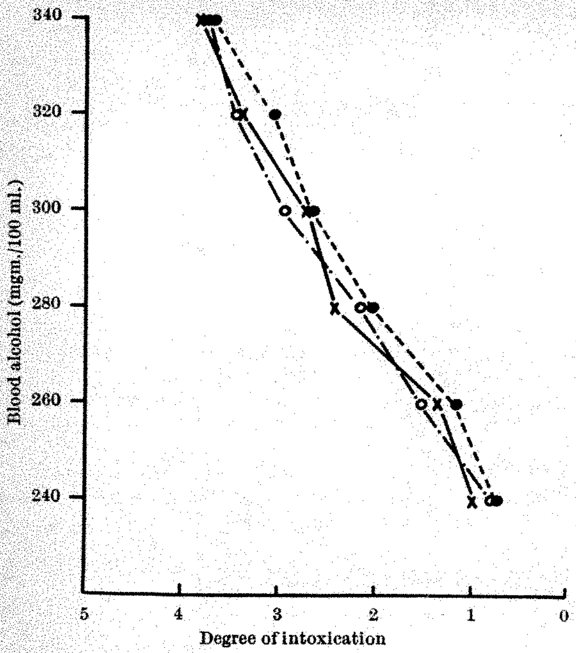

Fig. 1. Degree of intoxication at a given blood alcohol concentration in the same group of 4 dogs with and without pre-medication with triiodothyronine. ×—×, Control; ○—·—○, triiodothyronine 250 μgm; ●--●, triiodothyronine 375 μgm.

in the laboratory more than three months, and had received numerous similar alcohol injections at intervals of not less than one week. Group 1 consisted of 4 dogs. Their average rate of fall in concentration of blood alcohol on control runs was 20·9 mgm. per 100 ml. blood per hr. When 250 μgm. triiodothyronine were administered to the same dogs 30 min. before the alcohol injection the rate was 19·3, while with 375 μgm. triiodothyronine it was 19·1, an insignificant difference. Fig. 1 shows that with the smaller dose the degree of intoxication at a given concentration of alcohol in the blood was almost identical with the control, while the larger dose evoked a small but probably not significant improvement in performance.

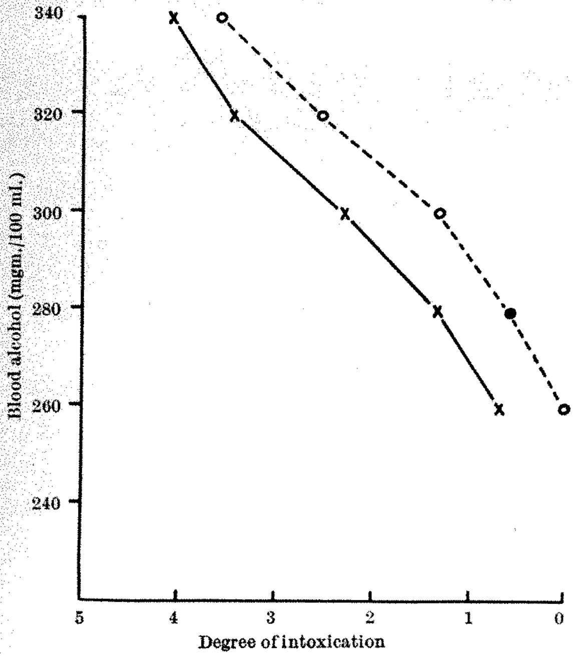

Fig. 2. Degree of intoxication at a given blood alcohol concentration in the same group of 6 dogs with and without pre-treatment with triiodothyronine 2·5 or 5·0 mgm. at 20 hr., and again 30 min. before administration of alcohol. ×—×, Control; ○--○, triiodothyronine

Group 2 consisted of 6 dogs. Their control rate of fall of blood alcohol was 20·9 mgm. per 100 ml. Four of these dogs received 2·5 mgm. triiodothyronine at 20 hr. and again at ½ hr. before the alcohol injection. The remaining two received 5·0 mgm. at each of these times. The only symptoms shown by the dogs after these very large doses of triiodothyronine were some panting and a transient rise in temperature of not more than 1 deg. C. The rate of fall of blood alcohol after triiodothyronine was 21·3 mgm. per 100 ml., an insignificant increase over their control value. Fig. 2 shows that with these very large doses of triiodothyronine the degree of intoxication was about 1 degree less at all blood alcohol concentrations, or, in other words, the same degree of intoxication occurred at a blood alcohol concentration about 20 mgm. per 100 ml. higher than in the control runs.

The small but significant reduction in the degree of intoxication brought about by triiodothyronine would indicate, if applied to man, that about one more drink could be consumed before reaching a given degree of drunkenness. If the dog and man show a comparable response to triiodothyronine, the effective dose for man would be in the vicinity of 12·5–25 mgm., which is much in excess of any reported dose. The possibility of species difference would indicate the desirability of repeating the work with human subjects, using maximal safe doses of triiodothyronine.

Adrenal Cortical Function in the Pregnant Sheep

Relatively little is known regarding the role of the adrenal cortex in human pregnancy. Conflicting reports appear in the literature on steroid excretion-rates in women during normal pregnancy. Some workers[1] have found no change in 17-ketogenic steroid excretion in the last trimester of pregnancy, while others[2], using the same chemical method for their estimation, report a slight increase in levels. In contrast, Venning[3], employing a bioassay technique as a measure of adrenal activity, found an initial rise in excretion of glycogenic corticoids in the first trimester of human pregnancy. This later returned to normal values with a falling-off in excretion-rate usually occurring in the last month. Shortly after parturition the values were back to normal levels again.

It was therefore decided to initiate a preliminary study on the ewe to see if any noticeable change in urinary corticoid excretion occurred in this animal during pregnancy and post-partum. This was part of a more extensive study on a possible relationship between adrenal function and birth-weight of the lamb.

Four ewes were observed over the period from conception to lambing and during a few weeks following parturition. Two of the ewes received intramuscular injections of adenocorticotrophic hormone during the last 3 months of pregnancy (dosages of 20 and 40 I.U./day respectively), while the remaining two were untreated.

The chemical method of Norymberski and Stubbs[1] was used for determining urinary excretion of steroids. This method estimates 17-ketogenic steroids. Included in this steroid group is tetrahydrocortisone, a metabolite of hydrocortisone, the main cortical steroid secreted into the blood-stream of sheep[4]. The finding that a marked rise in urinary steroid excretion (rise $>$ 200 per cent) was observed after administration of adenocorticotrophic hormone and a rapid fall occurred when injections of the hormone ceased (fall to 20 per cent) provided physiological justification for the method.

Results showed that, during the greater part of pregnancy, urinary steroid excretion in the sheep did not differ significantly from the seasonal fluctuation of high winter and low summer levels observed in the controls. This seasonal steroid pattern had also been observed previously in man[5]. However, of interest was the marked drop in steroid output which occurred towards the end of pregnancy in all animals studied, treated and untreated with adenocorticotrophic hormone. The urinary output remained still very low immediately following the birth of the lamb, rose during the lactation period and showed a drop when lactation was terminated experimentally. These fluctuations are illustrated in Fig. 1, which is typical of the responses shown by all the animals observed.

A more detailed investigation is being undertaken which will give day-by-day information of steroid excretion-rates over the last month of pregnancy. This should show if the drop in output occurs suddenly or shows a stepwise fall over several days or weeks.

The noticeable fall in steroid excretion just prior to parturition may have one of several explanations:

(1) Reduced adrenal cortical activity; (2) altered enzyme activity in the adrenal gland, such as the possible metabolism of progesterone to the steroids concerned with salt and water transfer—corticosterone and aldosterone—rather than its hydroxylation to hydrocortisone; (3) a possible drop in level of circulating progesterone of extra-adrenal origin affecting the amount of adrenal steroid production; (4) reduced stimulus for a possible extra adrenal source of corticosteroids.

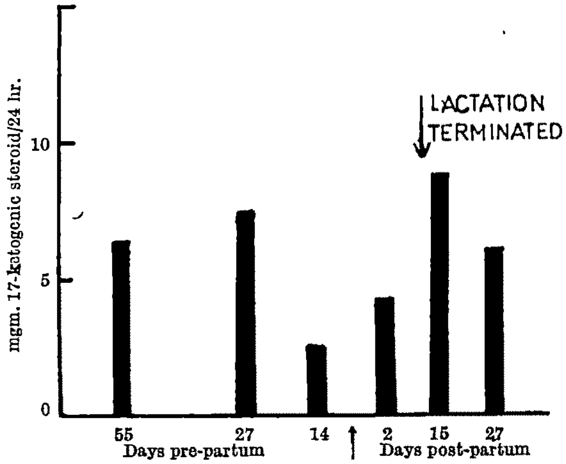

Fig. 1. Urinary 17-ketogenic steroid output in a pregnant ewe before and after parturition. A marked drop in corticoid excretion occurred towards the end of pregnancy, preceding parturition

Further work is required to be done before an adequate explanation can be formulated.

This study was financed by the National Health and Medical Research Council of Australia.

The assistance of Mr. L. Morris in the management of the animals is gratefully acknowledged.

Effect of Dietary Phytate on Fæcal Absorption of Radioactive Ferric Chloride

IT has been stated that diets with high phosphate, phytate and low calcium content affect iron absorption by precipitating the iron as an insoluble iron phytate or phosphate; and that this might be a factor in the etiology of the widespread and severe iron-deficient anæmias of the tropics[1-6]. It is known that bulk has a deleterious effect on iron absorption.

Most tropical diets are rich in phosphate and phytates, have a low calcium content and consist largely of bulky carbohydrates. Such diets might be expected to hinder iron absorption.

The approximate milli-equivalents in an 'average' tropical diet of calcium is 20, phosphate 32, phytate 12, iron 0·7 (20 mgm. Fe^{2+}). If combination of iron with phytates and phosphates occurs in the gut it might be expected that on such a diet little iron would remain free; supplementary iron might leave excess of the metal free for absorption. Although the role of calcium in iron absorption is somewhat controversial, calcium in excess might be expected to form calcium phytates and phosphates, and thus reduce the quantity of these compounds available for combination with iron[7-12].

It is likely that all these compounds are mutually reacting and the changes in one will affect the others, and no one of them can be regarded as exclusively concerned in hindering iron absorption or otherwise.

To ascertain the effect of dietary phytates on intestinal iron absorption we have used 6·0–10·0 μc. of oral $^{59}FeCl_3$ with 5 mgm. of carrier in a form of ferrous sulphate with ascorbic acid, and estimated the radioactivity of the stools daily. Absorption of iron was determined by measuring the differences between the activity of the radioiron given and the unabsorbed activity recovered from the fæces; utilization was measured by determining the amount of radioactivity that appeared in the circulating blood as newly synthesized hæmoglobin; this has been found to be the most accurate for determining the iron absorption[13].

The radioactivity of the wet stools was estimated using a ring of six 10-in. matched halogen-quenched Geiger–Müller tubes. The stools were then dried and powdered and the activity re-measured in the Geiger–Müller counter as well as in a scintillation counter using a 1½-in. thallium-activated sodium iodide crystal.

The subjects, non-anæmic healthy African adults, were given 50 gm. wholemeal bread spread with jam to which was added 3 gm. of 12-sodium phytate; 10–15 ml. water containing the $^{59}FeCl_3$ were then drunk and after this a further 50 gm. of wholemeal bread given. In this way dietary bulk was kept constant. All the stools thereafter were collected daily and analysed separately until they contained less than 1 per cent of the administered radioactivity. One week after this level had been reached, a second similar dose of $^{59}FeCl_3$ was given, but this time with identical amounts of white bread and no phytate. Duplicate tests were then made on the same individuals, reversing the order in which the phytate-fortified diet was given.

Our results indicate that the effect of excess 12-sodium phytate on intestinal iron absorption is varied. In some cases phytate may decrease iron absorption by 20 per cent. For example, an individual given 6 μc. of oral $^{59}FeCl_3$ with 5 mgm. of carrier but no phytate excreted 57 per cent of the administered dose of iron. A second test made on the same individual with the same amount of iron and a similar diet but the latter fortified with 3 gm. of 12-sodium phytate gave an excretion rate of 74 per cent, and a fourth test made without phytate gave an excretion value of 82 per cent (Table 1).

Table 1. PERCENTAGE OF IRON EXCRETED

Case No.	No phytate	3 gm. phytate	No phytate
1	57	74	82
2	88	70	68
3	60	58	76
4	72	85	62
5	80	70	85

These iron excretion-rates are lower than those found in normal European and American subjects, and approximate to the excretion values found in anæmic patients in America and Britain. Perhaps this is because the iron stores, as estimated by the iron content of bone marrow, are lower than in Europeans and Americans.

Under the conditions of this experiment and using 12-sodium phytate, there were great variations in the amount of iron absorbed and the effect of phytate on its absorption was not constant.

In man, intestinal iron absorption is not constant, the same individual absorbing different amounts at different times and different individuals have varying absorption-rates. Anæmic individuals generally absorb more iron than non-anæmic, and this is not directly associated with the hæmoglobin values or the extent of their iron stores. Our work, however, was all done on the same non-anæmic individuals, and the different excretion-rates cannot therefore be due to either anæmia, or variations in the extent of their iron stores.

It is unlikely that differences in iron absorption on phytate-fortified diets are due to variations in the hydrolysis of phytic acid to inositol and orthophosphoric acid in the gut. Part of the phosphate thus liberated would be available for either absorption or combination with other metals. The extent to which dodeca-sodium phytate undergoes hydrolysis in the gut of man has not yet been worked out but is probably high. It is possible that phytates *per se* have no adverse effect on iron absorption but that the products of its hydrolysis may, in so far as they increase the milli-equivalents of phosphates present in the gut which could combine with available iron and/or calcium. Many animals, particularly the rat, have phytase-producing bacteria in their gut which decompose the phytates before they precipitate iron or calcium; whether this happens in man is unknown. Since dietary bulk was kept constant in all our tests, this is not likely to have entered into the variations in iron absorption.

Whatever part calcium, phosphates and phytates are ultimately found to play in iron absorption and the etiology of tropical iron-deficient anæmias, the work of Hernden and his associates[14] with D-sorbitol makes it evident that the composition of the diet and the intestinal contents play an important part in iron absorption.

Full results of this work will be published elsewhere.

BIOLOGY

Radiosensitivity as a Function of Antigenic Equivocation

RECENT studies of factors modifying the response of mammalian tissues to radiation have led to results which cannot be interpreted on existing theories, and a more comprehensive hypothesis on the nature of radiation reactions in multicellular organisms seems necessary. Previous studies on the *C3H* mouse mammary carcinoma had shown that its radiosensitivity apparently depends on an auto-immunizing mechanism or similar manifestation of host resistance, and is consequently determined largely by the degree of genetic and antigenic diversification between host and tumour. This interpretation, however, is not sufficient to explain more recent results on the induced radiosensitization of unmodified isogenic tumours by inoculation of the host with a second, suitably attenuated, inoculum. For example, irradiated isogenic tissues, including tumour isografts given a dose sufficient to prevent their 'taking', will, when inoculated into a mouse already bearing a growing tumour graft, render the established tumour materially more radiosensitive[1].

Since isologous transplants are, by nature, not antigenic in the classical sense, it was concluded that the irradiated inoculum must contain a new or modified antigen capable of influencing a pre-existing balance between the growing tumour and

Table 1. Effect of Various 'Antigens' on the Radiosensitivity of the *C3H* Isologous Tumour treated *in situ* with 4,200 r.

Sensitizing inoculum	No. of mice	Number cured	Cures (per cent)
Uninoculated controls	108	0	0
Irradiated *C3H* tissues, < 5,000 r.	92	26	28
7,000 r.	72	28	39*
10,000 r.	44	8	18
Isografts (unirradiated *C3H* skin)	22	0	0
Hybrid grafts (F_1 and back-cross skin)	44	7	16
Homografts (albino mouse tissues)	74	24	32*
Heterospecific grafts (rat skin)	22	4	18
Heterogeneric proteins (unrelated tissues)	24	0	0

* Note the similarity between homografts and optimally irradiated isografts in their radiosensitizing capacity.

resistance factors in the host. This conclusion has since been confirmed by the demonstration of antigenic changes appearing in irradiated tumours[2] and host tissues[3].

If the radiation-attenuated sensitizing inoculum acts through the formation of a new antigenic constituent, then one would expect that unirradiated homologous tissues from other strains or closely related species, having antigens resembling, but not identical with, those of the tumour, should also have a potent radiosensitizing action. Experiments designed to test this prediction gave positive results (Table 1). Living skin from homologous and related hybrid donors, as well as other homologous tissues and even heterologous skin from a related genus, did in fact succeed in sensitizing the tumour. As in the case of radiation-attenuated isografts, optimal sensitization was obtained when the antigenic constituents of the inocula resembled, but were neither identical with nor too divergent from, the antigens of the tumour and host.

These complex interactions can, it would seem, best be analysed in terms of biological information theory[4]. The effect of irradiation on intracellular structure and function has been ascribed to tautomeric re-arrangement of molecular configuration in the nucleic acids[5], equivalent to the superposition of 'noise' or 'equivocation' upon a specific signal. This would be expected in turn to alter the specific pattern of newly synthesized tissue antigens, including those concerned with homeostatic control of proliferation and growth. Thus radiation-induced equivocation could also affect intercellular regulatory processes.

When a tissue is irradiated *in situ* the degree of equivocation, in effect the noise/signal ratio, apparently becomes sufficient for the autogenous cells to lose their specific identity, and hence become subject to immune processes such as the homograft reaction. The similarities between radiation effects and the phenomena of transplantation immunity have been discussed elsewhere[1]. The inoculation of radiation-attenuated isografts or of genetically incompatible homografts into tumour-bearing animals, both amount to the injection of distorted information into the intercellular feedback system, thus disturbing the existing relatively tolerant host–tumour relationship. This should amplify the effects of local irradiation, and hence account for the induced radiosensitization of tumours.

Since 'information', in the sense used above, is carried by specific material entities, it can be postulated that the 'equivocated substances' generated by irradiation of tissues must be mobile, reaching distant lymphoid tissues in order to evoke the immunological reactions described; diffusible, affecting areas adjacent to the treated site and determining the radiation reaction at these points; and unstable, the local concentration tending to diminish during the post-irradiation period, resulting in a dependence on time in the dose–response relationship. While the first accounts for the experimental results described, the two latter postulates promise to throw some light on the mechanisms underlying the time and volume parameters affecting dosage in clinical radiotherapy.

The 'diffusion' effect has been observed in irradiated human tissue by the increased radiosensitivity of skin adjacent to another treated area, and by the dependence of the intensity of the reaction upon the size and shape of the treated field[6]. Similarly, loss of activated material by decay or reversion to the ground-state amounts to partial 'recovery' from the effects of radiation. The material is likely to be a heterogeneous mixture, and if each product is assumed to decay exponentially the total residual activity, given by the sum of the exponentials, should approximate to a 'power function'[7]. This is in line with the clinical observation that the dose (D) which, when delivered over an extended period (T), is equivalent in effect to a single instantaneous exposure (E), is given to a very close approximation by the power function $D = E \times T^n$, n being a positive fraction[8].

The foregoing 'equivocation' hypothesis could serve to systematize a complex body of data in the field of experimental mammalian radiation biology, and might also furnish a satisfactory explanation for the time and volume factors as they affect the radiosensitivity of human tissues and tumours.

Demonstration of Endogenous Pyrogen in Serum during Systemic Tuberculin Reaction in Rabbits

Substances capable of producing fever in normal recipients (the so-called endogenous pyrogens) appear in the serum of experimental animals during fever due to bacterial endotoxin, influenza virus and streptococcal and pneumococcal infections[1]. Systemic tuberculin reaction is very similar to the effect of bacterial endotoxins[2]. An attempt has therefore been made to demonstrate the presence of substances with an effect corresponding to that of endogenous pyrogen in the serum of experimental rabbits during systemic tuberculin reaction.

Induction of hypersensitivity in rabbits with B.C.G. infection, signs of systemic tuberculin reaction and passive transfer of hypersensitivity with white blood cells and spleen cells have been described elsewhere[3]. Blood was collected under sterile conditions by cardiac puncture approximately 2 hr. after intravenous administration of purified tuberculin (0·005 mgm. PPD). It was allowed to clot, kept overnight in an ice-box, the serum was drawn off, centrifuged at 2,000 r.p.m. for half an hour and kept at − 20° C. All glass used, syringes and needles were washed thoroughly in water free of pyrogen before sterilization and all sera were tested for sterility. Rabbits were rendered tolerant to endotoxin by 10 daily injections of 10^8 heat-treated *Salmonella paratyphi B*. Tolerance was tested daily by taking body-temperatures after injection of *S. paratyphi*; the sera were tested on the first day after the last injection of the vaccine. Sera were injected intravenously in doses of 10–25 ml. Body-temperatures were recorded with a rectal thermometer twice within the $\frac{1}{2}$ hr. preceding the experiment and then $\frac{1}{4}$, $\frac{1}{2}$, 1, 2, 3 and 4 hr. after injecting the serum. Rabbits having a temperature higher than 39·5° C. or showing a difference of more than 0·2 deg. C. between the measurements before the experiment were not used.

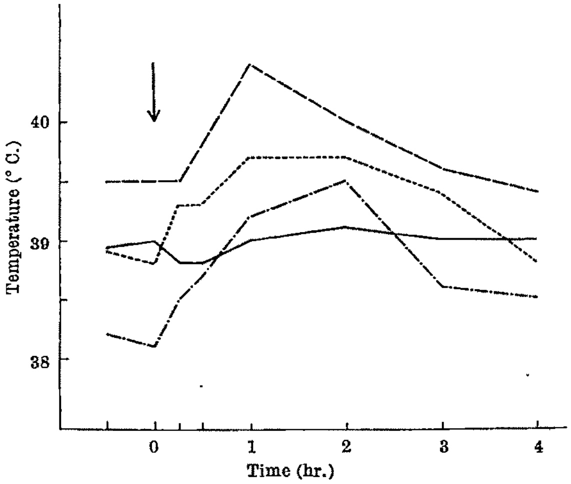

Fig. 1. Rectal temperature changes in rabbits after intravenous administration (arrow) of 20 ml. of sera obtained from: ———, normal rabbit; ......, actively sensitized rabbit injected with 5 μgm. of PPD; —·—·—, actively sensitized rabbit injected with 5 μgm. of PPD, serum being given to endotoxin-tolerant recipient; ----, rabbit passively sensitized with hypersensitive cells, injected with 5 μgm. of PPD

Fig. 1 shows a typical effect of normal serum and serum collected during systemic tuberculin reaction. In all positive cases the result was similar: a short monophasic fever without a latent period. With control sera the increase in temperature was usually not more than 0·2 deg. C.; sometimes the temperature decreased. The difference in temperature produced 1 hr. after injection of serum was taken as the criterion for evaluation of the experiments (Table 1). It is evident that the large majority of control sera gives negative results. The sera collected during the systemic tuberculin reaction in rabbits that had been rendered hypersensitive, actively or passively, gave mostly positive results. These results cannot be ascribed to the effect of non-specific endotoxic substances which are known to be present in non-purified tuberculin[4].

Table 1. APPEARANCE OF FEVER IN RABBITS INJECTED INTRAVENOUSLY WITH FEBRILE AND NON-FEBRILE SERA

The number of negative, moderately positive and positive results is shown. + indicates fever induced; − indicates absence of fever

Characteristics of the sera used			Rise in body temperature in recipients (deg. C.)		
Experimental groups of rabbits	Injected with	Fever response	0–0·3	0·5–0·7	0·8–1·3
BCG sensitized	PPD	+	11	8	9
	PPD	+*	—	1	4
	—	—	10	—	—

Passively sensitized with cells	PPD	+	4	6	3
	—	—	4	—	—
Acceptors of normal cells	PPD	—	6	—	—

* Given to recipients tolerant toward endotoxin.

The fundamental characteristics of an endogenous pyrogen are the ability to induce a short immediate fever and the preservation of this ability on transfer to rabbits tolerant toward endotoxin[1]. Both these points have been demonstrated in present experiments. The results in Table 1 show that an endogenous pyrogen is produced by a reaction between a small amount of purified tuberculin and cells of hypersensitive rabbits, both in actively sensitized rabbits and after transfer of hypersensitive cells into normal recipients.

Virus-like Particles in chemically induced Carcinoma of the Uterine Cervix

THE ultra-microscope structure of carcinoma cells has been thoroughly studied, but essential differences between neoplastic and normal cells have so far not been established, with the possible exception of so-called 'virus-like particles'[1].

Virus-like particles are reported to occur in mammary carcinoma of mice known to carry the milk factor[2–4] and several groups of investigators interpret these particles as the materialization of the mammary tumour virus. Pitelka *et al.*[5] demonstrated the presence of identical virus-like particles in hyperplastic alveolar nodules of the mammary gland of the *C3H/He CGRL* mouse, a lesion generally considered as a precursor of mammary carcinoma. Howatson and McCulloch[6] described virus-like particles in a transplantable mouse plasma cell tumour which originated in a female *C3H/He* mouse. To the best of our knowledge, these characteristic particles have not been found in chemically induced tumours.

Our material consists of virgin *C3H/A* mice, a number of which has been treated with bi-weekly applications of 3,4-benzopyrene. Invasive cervical carcinoma occurred after forty weeks. Ultra-thin sections of these tumours were examined in the electron microscope. The ultra-morphology of the tumours has been described elsewhere[7]. In a certain number of slides, we found intra- and extra-cellular

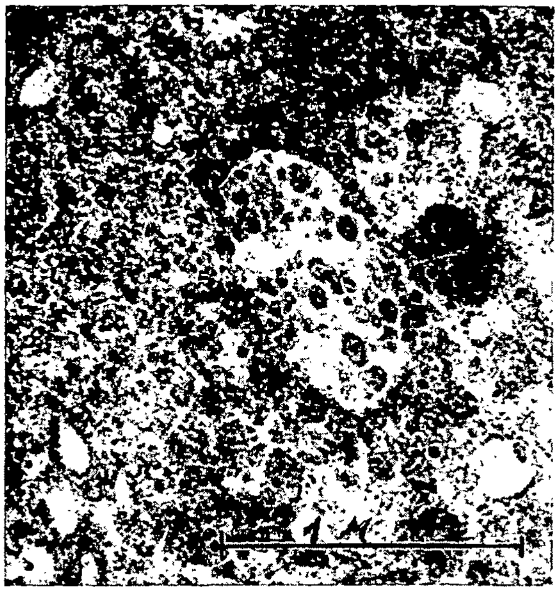

Fig. 1. Virus-like particles gathered into an elliptical cluster in the cytoplasm of a chemically induced cancer cell of the uterine cervix of a mouse

particles morphologically indistinguishable from the virus-like particles described in mammary tumours (Fig. 1).

The particles are almost circular in shape with an external diameter of 500–800 A. The centre is often found empty, but sometimes contains a dense core, 300–400 A. in diameter, surrounded by one or two concentric membranes separated by an interspace of lesser optical density. The number of particles per cell section varies. The corpuscles are scattered through the cytoplasm or gathered into irregular elliptical or circular clusters. Particles may be seen surrounding intra-cytoplasmic vacuoles. Tumour cells heavily laden with particles were often found in the immediate vicinity of others containing no particles whatsoever. The intercellular spaces, large and irregular, often showing deep infoldings of the plasma membranes, may harbour large numbers of virus-like particles. Irregularly shaped inclusions of dense homogeneous material are encountered within the cytoplasm of several neoplastic cells. Scattered throughout the matrix of these amorphous inclusion bodies, varying numbers of characteristically shaped particles may be found.

Virus-like particles have not been discovered in liver, spleen, intestine, colon, breast or pancreas of treated mice.

The presence of virus-like particles in a chemically induced carcinoma of the cervix is puzzling, even though *C3H/A* mice are known to have the milk factor and to be disposed to mammary carcinoma.

For several reasons, it needs a stretch of the imagination to admit that the chemically induced uterus cancer of mice would be caused by a virus. As a matter of fact, in contradistinction with the breast cancer, carcinoma of the cervix scarcely ever occurs spontaneously in mice. Furthermore, polycyclic hydrocarbons can induce tumours in almost any organ of this animal.

We cannot prove, of course, that the particles described are not simply due to casual viral infection, though we do not understand why contamination should remain confined to the cervix. Should casual infection be proved, it still would not have any bearing on the induction of a (necessarily pre-existing) tumour. A hypothesis demanding further investigation is whether these virus-like particles should not be considered as a morphological substratum of the neoplastic reaction, an assumption which applies as well to spontaneous as to experimentally induced tumours. In other words, we wonder whether virus-like particles may not happen to be a result, rather than the cause, of the carcinomatous process.

This investigation was supported in part by a research grant from the Fonds National de Recherche Scientifique.

Histochemical Demonstration of A and B Antigens in Platelets

The existence of A, B, AB and O groups in platelets has been shown by Gurewitch and Nelken[1], and confirmed by other authors. This communication deals with the application of fluorescent antibody technique[2] for the investigation of platelet antigens.

Blood samples from A, B, AB and O donors were obtained in 'Complexon III'. The platelets were separated by differential centrifugation and washed twice in phosphate-buffered saline *p*H 7·0. Rabbit and chicken[3] anti-human globulin sera were used for conjugation with fluorescein *iso*thiocyanate (kindly provided by Difco). The conjugation procedure was as follows: to 6 ml. of anti-human globulin serum the following solution was added: saline 6·25 ml.; buffer CO_3-HCO_3 0·5 *M*, *p*H 9·0, 2 ml.; and acetone 1·25 ml. Fluorescein *iso*thiocyanate (25 mgm.) was added directly to the reaction mixture with stirring and stored for 18 hr. in an ice-box. The unconjugated fluorescein was removed by dialysis at 4° C. against 0·15 *M* sodium chloride, 0·01 *M* phosphate buffer *p*H 7·0, for a period of 5–6 days. The third conjugate used in the experiments was a sheep anti-rabbit globulin fluorescein conjugate (a commercial preparation of Sylvana Chemical Co.). All conjugates were heated at 56° C. for 20 min., thoroughly absorbed with washed thrombocytes and red cells and checked for the presence of specific antibodies prior to use. The absorption is a very important step of procedure, since platelets may non-specifically bind the stained protein molecules from unabsorbed conjugates.

Two staining procedures were performed. First, two drops of A, B or AB platelets suspension (approximately 8,000,000 cells per ml.) were mixed with corresponding anti-serum (anti-A, anti-B, or anti-A,B) and left for 2 hr. at 20° C. The cells were then washed three times in buffered saline and to one drop of suspension four drops of chicken (or rabbit) anti-human globulin conjugate were added. The incubation lasted for 90 min. at room temperature followed with one washing of platelets. Finally, the cells were resuspended in glycerol containing 10 per cent buffered saline, and one small drop of suspension was transferred on to a slide and flattened with cover slip. Each suspension was checked for number and conditions of cells with a phase-contrast microscope. Controls for first staining procedure were : (*a*) platelets plus conjugate ; (*b*) platelets from group A plus anti-B serum plus conjugate, and cells from group B plus anti-A serum plus conjugate. The second staining procedure was similar to that already described for leucocytes[4] : (*a*) platelets were exposed to anti-serum as above ; (*b*) the cells were washed and treated with rabbit anti-human globulin serum at 37° C. for 2 hr. (serum absorbed with thrombocytes and red cells was used) ; and (*c*) washed platelets were brought into contact with the sheep anti-rabbit globulin conjugate and incubated for 90 min. at room temperature. Controls for the second procedure were as follows : (*a*) platelets plus conjugate ; (*b*) platelets from group A plus anti-B serum plus conjugate, and cells of group B plus anti-A plus conjugate ; (*c*) cells plus anti-human globulin serum plus conjugate (anti-serum was omitted) ; and (*d*) platelets plus anti-serum plus conjugate (anti-human globulin serum was omitted). A Reichert fluorescent microscope equipped with dark-field condenser and an Osram *HBO* 200 mercury lamp was used. The microphotographs were taken on Agfa 'Fluorapid' film.

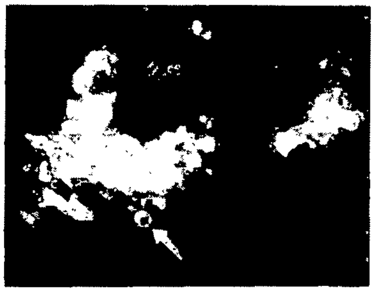

Fig. 1

The results have shown that the positive staining is only obtained when A, B or AB platelets were treated with anti-A, anti-B or anti-AB serum respectively. Thrombocytes from group O exposed to anti-A, anti-B or anti-AB serum did not show the fluorescence. The same holds for all controls. Fig. 1 (× 500) shows brightly stained clumps of platelets from group A treated with anti-A and chicken anti-human globulin conjugate (the arrow shows a stained erythrocyte). Both staining procedures were proved to be useful in demonstrating A and B antigens in thrombocytes. It should be pointed out that the method described here is performed on the cell suspension and includes specific adsorption of all reagents. No fixatives were used. Since we have succeeded in staining leucocytes[4] and red cells[5] specifically using fluorescein-labelled antibodies, it seems that fluorescent antibody technique may be successfully applied in the field of immunohæmatology.

We are indebted to the Institute for Nuclear Sciences, Vinča, for making a fluorescent microscope available for this study.

T2 Phage Infection of 'Protoplasts' obtained by Penicillin Treatment of *Escherichia coli B*

It was observed by Lederberg[1] that cells of *E. coli B*, grown in the presence of penicillin, changed in hypertonic solutions to spherical corpuscles that were readily lysed when transferred to a hypotonic medium. These corpuscles exhibited osmotic characteristics similar to those of various bacterial protoplasts. We have studied the adaptive activity to synthesize β-galactosidase of *E. coli B* 'protoplasts' obtained by penicillin treatment, according to Lederberg's method. We found that the addition of *T*2 phage immediately stops β-galactosidase synthesis, as it does in *E. coli B* cells[2]. The present communication deals with the mechanism of this process.

For the preparation of 'protoplasts' 90 ml. of a culture of *E. coli B*, grown overnight at 37° C. in a nutrient broth similar to 'Difco Penassay', was added to 210 ml. of the same medium containing 20 per cent sucrose, 0·20 per cent magnesium sulphate and 1,000 units/ml. of penicillin. The mixture was shaken for 3 hr. at room temperature. As revealed by phase-contrast microscopy, the above treatment changed 95 per cent of the cells to round corpuscles. The 'protoplasts' thus obtained were centrifuged and resuspended at 1×10^8/ml. in broth containing 0·6 *M* sucrose and 2 per cent serum albumin, and infected with *T*2 phage at 6×10^8/ml. After 5 min. the sample was diluted to 1 : 100 and was shaken at 30° C. in a water-bath. The hundredfold dilution of the samples is very important, not only for inhibiting the re-adsorption of the resulting phage particles, but also because the lysed 'protoplasts' inactivate the free *T*2 particles very quickly. *E coli B* cells, serving as controls, were treated in the same way except for the addition of penicillin. For the determination of phage particles during their multiplication cycle we used the premature lysis method of De Mars[3].

As shown in Fig. 1, under these experimental conditions the *T*2 phage can infect the cells as well as the 'protoplasts' derived from them, and both can synthesize the virus at nearly the same rate. No phage synthesis was observable when the 'protoplasts' were incubated for 10 min. in a hypotonic solution (0·9 per cent sodium chloride) before infection, because of the resulting osmotic lysis.

As in normal bacterial cells the receptors for *T*2 phage are known to be present in the cell wall, the above findings suggest that the treatment with penicillin does not cause general damage to this structure. If it is assumed that the *T*2 phage receptors are bound exclusively to the lipoprotein component of the cell wall[4], the phenomenon observed can readily

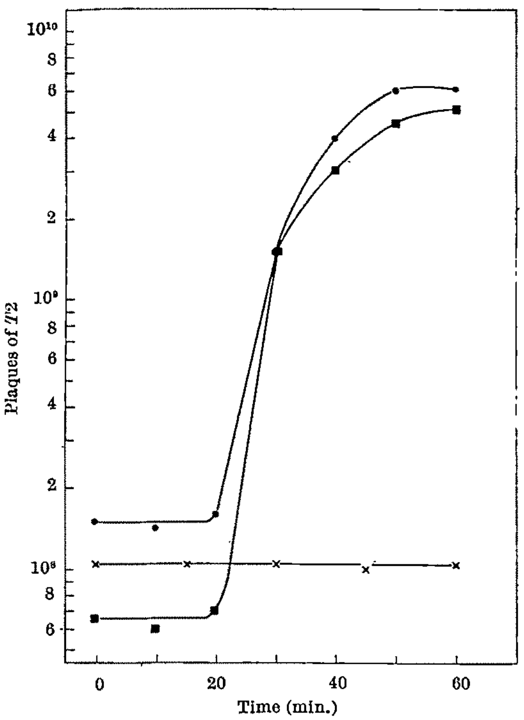

Fig. 1. Multiplication of $T2$ phage. ●—●, In *E. coli B* cells; ■—■, in 'protoplasts'; ×—×, in lysed 'protoplasts'

be explained, as penicillin is supposed to inhibit only the synthesis of the mucocomplex component[5–7] responsible for the rigidity and the actual morphology of the cell wall[8].

We are inclined to think, on the basis of our observations, that certain cell preparations of McQuillen[9] may also have had more or less cell-wall components on their surface.

When accepting the proposed definition for protoplasts[10], the spherical particles obtained from *E. coli B* by penicillin treatment can scarcely be considered as typical, since they are sensitive to $T2$ phage infection, that is, they seem to have the appropriate receptors undamaged on their surfaces.

The Inferior Mesenteric Ganglion in Man

The inferior mesenteric ganglion has been studied in the cat by A. J. Harris[1] and in the rabbit by G. Brown and J. E. Pascoe[2]; but in man, however, no full description of the anatomy of the ganglion itself has yet appeared.

A series of 19 stillbirths and neonatal infants, ranging from 7½ months to full term, were dissected after having been injected with embalming fluid through the umbilical vein.

The inferior mesenteric plexus was easily found by tracing down the intermesenteric nerves to their junction with it. The plexus was then dissected very carefully under a powerful lens, the nerves being teased away with a fine dissecting needle until a solid white structure, the inferior mesenteric ganglion, was isolated. In each specimen one or two ganglia were found, variable in size, and although some were small they all could easily be seen with the naked eye. They were in close proximity to the inferior mesenteric artery, being placed on either its left or right side. In three specimens two separate ganglia were found receiving nerves from their respective sides. Branches from the left ganglion tend to run to the distal part of the transverse colon, descending colon and upper part of the pelvic colon; while those from the right one accompanied the parent artery into the pelvic mesocolon to innervate the lower part of the sigmoid colon and upper part of the rectum.

The inferior mesenteric ganglion is a well-defined body capable of isolation and may be said to be a constant structure in man. It is an important relay station in the nerves to the distal part of the large intestine.

Further details of this work will be presented for publication at a later date.

A New Leech-infesting Cercaria from Duddingston Loch, Edinburgh

Valvata piscinalis, a common snail in the Duddingston Loch, Edinburgh, was found infected with a new furcocercous cercaria. Of 758 snails examined, 19 were found infected. This cercaria, which is named *Cercaria valvatae* n.sp., develops in long tubular sporocysts forming a tangled mass in the hepatopancreas of the snail. With the proliferation of the germ balls the tubular sporocyst becomes constricted into sausage-shaped swellings containing developing cercariae. The abbreviated specific diagnosis of *Cercaria valvatae* n.sp. (Fig. 1) is as follows.

Body, oval without eye-spots, 0·18–0·22 mm. long and 0·084 mm.–0·1 mm. broad. Anterior end beset with transverse rows of minute spines. Oral organ protrusible, 0·036 mm. × 0·025 mm. to 0·045 mm. × 0·03 mm.; divisible into two parts, anterior part thin, posterior part muscular. Ventral sucker equatorial or post-equatorial, highly muscular, protrusible, 0·027 mm. × 0·025 mm. to 0·03 mm. × 0·028 mm. Prepharynx small, pharynx globular, 0·014 mm. diameter, œsophagus 0·03 mm. long. Intestinal cæca extend slightly posterior to the ventral sucker. Penetration glands 3 pairs, bilobed, granular, posterior to ventral sucker, opening by long ducts at the base of oral organ. Excretory bladder, ovoid; flame cells six pairs, five in the body and one in the tail stem. Tail stem 0·16–0·23 mm. long. Caudal furci 0·19 mm.–0·21 mm. long, not provided with fin or membrane.

Of the furcocercous cercariae described from Great Britain this cercaria comes nearest to *Cercaria* F_1[1], *Cercaria Y*[2], *Cercaria micromorpha*[3] and *Cercaria pygocytophora*[4], but differs from these in the number of either the penetration glands or the flame cells.

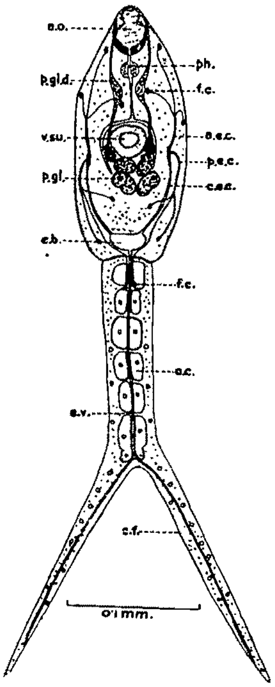

Fig. 1. *Cercaria valvatae* n.sp. showing morphological details

It is also distinct, besides other features, in the nature and number of penetration glands or flame cells from *Cercaria cristata* and *Cercaria longiremis* described from *Valvata piscinalis* from the Continent by Wesenberglund[5] as also from the cercariae of *Aptemon gracilis* and *Cotylurus cornutus* producing tetracotyle larvæ in leeches described by Szidat[6] and the American *Cercaria burti*.

A large number of infection experiments were tried with a variety of animals to find out the intermediate host of *Cercaria valvatae* n.sp. This revealed the quick penetration of this cercaria within 2–3 min. into the body of the leech *Helobdella stagnalis*, followed by casting of the furcocercous tail and entry into its hæmo-cœlomic system. In the next 3–4 days the cercarial structures were lost and in 7–8 days new structures developed and a cyst was secreted around the tetracotyle. The cysts were clearly seen in the body of the leech at this stage (Fig. 2). About 28 days were required between the cercarial penetration and the formation of a complete tetracotyle.

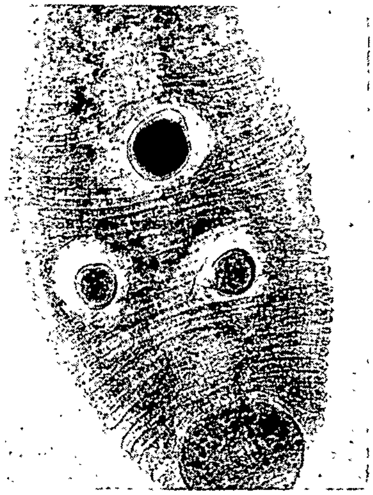

Fig. 2. Cysts of tetracotyle in the body of the leech

GENETICS

Linkage of Polygenes controlling Size of Ascospore in *Neurospora crassa*

IT has been shown in earlier work[1,2] that the size of ascospore in *Neurospora crassa* is controlled by a polygenic system. In the course of experiments designed to give further information on this system, results were obtained which indicate that a part of the polygenic system is linked with the albino locus on chromosome I.

The strains used were 232·1, 232·2, 232·3 and 232·4, all of which are albino (*al*-2), large-spored strains comprising a 4-spored ascus obtained from the sixteenth generation of selection for increased ascospore size[2].

These strains were crossed to the appropriate wild type and the crosses incubated at 25° C. 50 ascospores were randomly isolated from each cross. The F_1 ascospores were normal in size. The isolates thus obtained were each back-crossed to the large-spored parent. This gave a total of 29 crosses in which albino F_1 strains were back-crossed and 48 crosses in which non-albino F_1 strains were back-crossed. A sample of 50 ascospores from each cross was measured. The results are presented in Table 1.

The majority of back-crosses involving albino F_1 strains had mean ascospore-lengths in the range 19·42–22·30, while the majority of back-crosses involving non-albino F_1 strains had mean ascospore lengths in the range 17·26–18·92. The difference, 1·02 units, between the mean ascospore-length of the two groups of back-crosses is highly significant ($P < 0·001$ per cent), which indicates that some of the genotypic material controlling size of ascospore segregated in association with the albino locus. That is, there is linkage between this genotypic material and the albino locus. This genotypic material is responsible for approximately one-sixth of the total

Table 1. BACK-CROSSES OF *al* AND al^+ F_1 STRAINS TO LARGE-SPORED PARENTS

	al F_1 strains	al^+ F_1 strains
No. of back-crosses with mean in range 17·26–18·92	2	43
No. of back-crosses with mean in range 19·42–22·30	25	5
No. of intermediates	2	0
Total No. of back-crosses	29	48
Mean ascospore length*	19·84	18·82
Standard deviation of mean	0·019	0·033

For difference between means, $t = 13·077$; $P < 0·001$ per cent.
* 1 unit = 1·72μ.

response (about 6 units) to selection for increased ascospore size obtained over sixteen generations[2].

From Table 1 it can be seen that two out of the 29 *al* F_1 strains, when back-crossed, gave a mean ascospore-length in the 17·26–18·92 range, and five of the 48 *al*+ F_1 strains, when back-crossed, gave a mean ascospore-length in the range 19·42–22·30. It is reasonable to regard these exceptions as due to crossing-over occurring between the albino locus and the site of the genotypic material controlling this part of the response to selection for increased ascospore size. If this is so, then this genotypic material is located about 9 cM. from the albino locus, calculated on the assumption of seven recombinations in a total of 75 back-crosses. As yet it is not possible to say whether this site is proximal or distal to the albino locus.

The length of ascospore of the majority of back-crosses fell into one or the other of two distinct classes. There were, however, two *al* F_1 strains where the mean ascospore length of the back-cross was intermediate between the two classes. The mean ascospore-lengths of these two back-crosses were 19·18 and 19·26. These intermediate cases were probably due to the segregation of the genotypic material controlling the rest of the response to selection for increased ascospore size. These two intermediate cases have not been included in the approximate estimation of the degree of linkage of the genotypic material to the albino locus.

Further work is being carried out in order to establish more precisely the position of this part of the genotypic material controlling ascospore size. This work will be reported in more detail elsewhere.

Ratio of Visible to Lethal Mutations produced in *Drosophila* by Phenylalanine Mustard

The present experiments were undertaken in order to see whether we could confirm the high visible mutation-rate relative to the lethal mutation-rate induced in *Drosophila* by phenylalanine mustard as compared with X-irradiation, reported by O. G. and M. J. Fahmy[1]. Since this high visible rate would imply (1) the existence of loci specifically concerned with visible mutations and as a group qualitatively different from non-visible loci and (2) a specific effect of the agent on such loci, it seemed important that this work be repeated.

Wild-type males of *Drosophila melanogaster*, 12–30 hr. old, were injected intra-abdominally with approximately 0·001 ml. of a 10^{-2} *M* suspension of *p*-N-di(chloroethyl)amino - phenylalanine(phenylalanine mustard) in distilled water or in 0·75 per cent saline, the amount injected being sufficient to cause noticeable swelling of the abdomens. The survivors were tested for sex-linked recessive lethal and visible mutations by the Muller-5 technique. An average of 9–10 daughters from each treated or control male was tested for mutations, several of the sons of each female being carefully scrutinized for visible mutations. In some experiments all the sons of each female were examined for visible mutations with the expectation of detecting delayed mutants and also mutants of such weak expression that not all the F_2 red-eyed sons would show the mutant trait. Table 1 shows the results of these tests, as well as results from control males into which distilled water or 0·75 per cent saline only was injected (distilled water versus saline having been found to have no significant influence on the rate of mutation).

Although the mutagenic effectiveness of phenylalanine mustard in our experiments is shown by the lethal-rate in Table 1, no visible mutations were found. This fact is difficult to reconcile with the report of the Fahmys[1] that from phenylalanine mustard-treated males 381 recessive visible mutations were found among 25,622 'treated X-chromosomes' in a series giving 7 per cent of lethals. After allowance is made for the lower lethal mutation-rate in our experiments, we should have recovered at least 6 visible mutants if we had found visible mutations in as high a proportion to lethals as the Fahmys did, a number that differs significantly from the number (0) found by us. However, this number does not differ significantly from the 2 or 3 visibles that would have been expected if X-rays had been used as the mutagenic agent, since the ratio of visible to lethal mutations found previously by various workers using the same type of genetic technique is in the range of 1 : 7 to 1 : 10. The report of the Fahmys[1] that phenylalanine mustard produces a ratio of visible to lethal mutations of nearly 3 : 10 (279 visibles in a population containing 999 lethals) is not confirmed by our work, since our finding of no visibles does differ significantly from an expectation of finding 2 : 7 ($P = 0{\cdot}05$) or 2 : 10 ($P = 0{\cdot}02$). Thus the chemical used could not be as much as twice as effective as X-rays in producing visibles as compared with lethals.

In explanation of the discrepancy between our results and those of the Fahmys, it should be mentioned that the Fahmys used a method of detecting visible mutations different from that used by us and by X-ray workers in general, in that they looked particularly for their visibles in suspected lethal or semi-lethal cultures, examining these cultures until the very end of their hatching period (though this

Table 1

Agent	No. of males treated		No. of chromosomes tested (no. of lethals in parenthesis)		Mutation-rate	
	Brood 1 (0–6 days)	Brood 2 (7–12 days)	Brood 1 (0–6 days)	Brood 2 (7–12 days)	Lethal	Visible
Phenylalanine mustard	121	65	1,056 (15)*	742 (12)*	1·5 ± 0·3%	0
Distilled water or 0·75 per cent saline	113	90	1,048 (3)†	831 (1)	0·2 ± 0·1%	0

* Two lethals were obtained from each of three treated males and have been considered as being of common origin in calculating the error of the mutation-rate, in accordance with Muller's method of statistical treatment (ref. 2).

† One semi-lethal.

procedure is only mentioned in passing on one of their earlier publications[3] and came to our attention after the completion of the present experiments). As is well known, the few surviving males in semi-lethal cultures are often abnormal. The Fahmys's 'visible' rate, relative to complete lethals, would therefore be very high, since most workers would include semi-lethals of very low viability with the complete lethals rather than with visibles. Moreover, the exclusion of the semi-lethals from the lethal class would further increase the visible rate relative to the lethal rate.

In conclusion, it might be pointed out that a lethal is often a visible of very low viability and that the distinction between 'lethals' and 'visibles' is really a matter of convenience. On general grounds, therefore, it is scarcely to be expected that any mutagenic agent should specifically produce visible effects, as contrasted to lethal.

A Position-Effect Explanation of Gene Conversion

Gene conversion was the name given by Winkler[1] to the transformation in a heterozygote of a + allele into a mutant allele, or of one mutant into another. He intended to explain recombination and crossing-over through digenic conversion of allele A into a in one chromosome and simultaneously of a into A in its homologue. Monogenic conversion, in only one chromosome, should also be possible, but this would not easily be distinguished from mutation. More recently, conversion has been used only in the monogenic sense[2] in which it is demonstrated chiefly through tetrad analysis from heterozygotes Aa when the expected Mendelian segregation of $2A : 2a$ is not obtained.

However, tetrads with three mutants and 1 + spores may be produced also from intragenic cross-over, that is, cross-over which takes place within a gross locus subdivided into sub-loci corresponding to sub-alleles or pseudo-alleles[3]. Typical intragenic cross-over has been demonstrated, for example, in the adenine-3 gross locus of *Neurospora*[4]. In a gene b subdivided into sub-alleles b_1 and b_2, the cross of a b_1 by a b_2 strain may be represented as $b_1 + \times + b_2$, and this will give a tetrad $b_1 +, + +, b_1b_2, + b_2$. If no distinction is made between the phenotypes of b_1 and b_2, the apparent result is b, +, b, b, or three mutants to 1 +. This is apparent conversion, which may be separated from true conversion only when sub-alleles are distinguishable.

Variegated conversion—the production of variegation in a heterozygote, not attributable to any apparent chromosome aberrations—has been reported to occur in *Oenothera*[5], but further analysis will be necessary before it can be generally admitted. True conversion, not associated with variegation, may be called stable conversion or transmutation[6]. This is at present the most important form of conversion since it has been plainly demonstrated to occur in *Neurospora*[7,8], and very probably in *Saccharomyces*[2,9] and some other species. Its importance stems from the fact that it constitutes a proved exception to Mendelian theory.

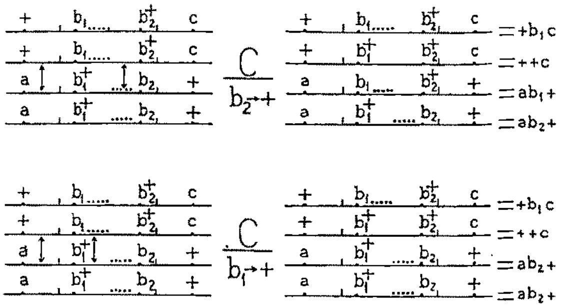

Fig. 1. Conversion of b_2 into + and of b_1 into +, corresponding respectively to asci 1 and 4 of Mitchell (ref. 7). Conversion results from relocation, by cross-over, of sub-alleles b_1 or b_2 adjacently to a different intermediary segment between them, which caused position effect (dotted) now reverting to +

Two types of explanations have been advanced for true, stable conversion: namely, a differential and compensatory reduplication, for example, the + allele reduplicating twice while allele a does not reduplicate[7]; and a transfer of chemical groups from one allele to the other, so as to result in a kind of mutation. The transfer might also be effected as a dislocation of groups similar to a kind of Thompson's episomes[10], or through enzymes and during gene reduplication[8], or by means of a transductor[11], reminiscent of transduction phenomena in bacteria. These are *ad hoc* hypotheses which lead neither to generalization nor to the possibility of prediction. An explanation is offered here, based on mechanisms known to operate at other levels, and which it is only necessary to extend to the intragenic level. Stable conversion is explained by intragenic cross-over which, by separating sub-loci, restores the intragenic position effect that caused the mutant phenotype. Fig. 1 shows how the explanation works for two of the asci in the clearly demonstrated case of *Neurospora*[7]. For simplicity of lettering, the loci studied by M. B. Mitchell[7] will be designated a for pyrimidine-1, b_1 for pyridoxine pH-sensitive, b_2 for pyridoxine non-pH sensitive, c for colonial. Other markers, located far from the b gross locus, are not necessary for this explanation. b_1 and b_2 are sub-alleles. Between them will be a segment of the b gross locus which causes position effect (see also legend of Fig. 1). Other conversion-asci are similarly explained. The explanation implies negative interference[3].

Details of this work will be published elsewhere.

FORTHCOMING EVENTS

*(Meetings marked with an asterisk * are open to the public)*

Monday, March 9

Royal Geographical Society (at 1 Kensington Gore, London, S.W.7), at 8.30 p.m.—Sir Charles Darwin, F.R.S.: "Darwin the Traveller".

Tuesday, March 10

Society of Chemical Industry, Agriculture Group (at 14 Belgrave Square, London, S.W.1), at 10.30 a.m.—Potash Meeting.

Zoological Society of London (at the Zoological Gardens, Regent's Park, London, N.W.1), at 5 p.m.—Scientific Papers.

Institution of Electrical Engineers, Education Discussion Circle (at Savoy Place, London, W.C.2), at 6 p.m.—Discussion on "The Laplace Transform—a Tool for the Electrical Engineer" opened by Mr. A. C. Sim.

Institute of Information Scientists (at the Berners Hotel, 10 Berners Street, London, W.1), at 6 p.m.—Symposium on "Russian Technical Information". Speakers: Mr. R. Sewell, Mr. A. Post and Dr. D. J. Urquhart.

Royal Aeronautical Society (at 4 Hamilton Place, London, W.1), at 7 p.m.—Mr. R. F. Jones: "Water and Ice in the Atmosphere".

Wednesday, March 11

Royal Society of Arts (at John Adam Street, Adelphi, London, W.C.2), at 2.30 p.m.—Dr. D. C. Martin: "Some Achievements of the International Geophysical Year".

Palæontological Association (at the Geological Society, Burlington House, Piccadilly, London, W.1), at 5 p.m.—Annual General Meeting. Prof. Gerhard Regnéll (University of Lund): "The Lower Palæozoic Echinoderm Faunas of the British Isles and Balto-Scandia".*

University of London (in the Hatton Lecture Theatre, Queen Mary College, Mile End Road, London, E.1), at 5.30 p.m.—Prof. C. P. Whittingham: "The Development of Experimental Botany"* (Inaugural Lecture).

Society of Chemical Industry, Food Group (at 14 Belgrave Square, London, S.W.1), at 6.15 p.m.—Dr. G. C. Whiting: "Organic Acid Metabolism in Cider Fermentations"; Dr. Jean Scott and Mr. E. J. Rolfe: "Vitamins of the *B* Complex in Cod and the Effect on them of Dehydration".

Thursday, March 12

Physical Society, Low Temperature Group (at the Institute of Physics, 47 Belgrave Square, London, S.W.1), at 9.30 a.m.—All-day Symposium on "Hydrogen Liquefaction and Associated Topics".

Royal Society (at Burlington House, Piccadilly, London, W.1), at 11 a.m.—Discussion on "The 'Ear' Under Water" opened by Prof. O. Lowenstein, F.R.S.

Imperial College (in the Department of Geology, Prince Consort Road, London, S.W.7), at 3.30 p.m.—Prof. Gerhard Regnéll (University of Lund): "The Lower Palæozoic Rocks of Sweden".*

Institution of Electrical Engineers, Utilization Section (joint meeting with the London Graduate and Student Section, at Savoy Place, London, W.C.2), at 5.30 p.m.—Mr. A. P. Foster: "Coalmining and Electricity"; Mr. P. D. House: "Electric Drives in the Paper Industry"; Mr. M. J. L. Willison: "Standardization and Simplification of Switchgear".

Royal Aeronautical Society (at the Institution of Mechanical Engineers, Birdcage Walk, Westminster, London, S.W.1), at 6 p.m.—Monsieur l'Ingénieur Général de l'Air Noël Daum: "The Griffon and the Prospect of Combining the Turbo-Ram-Jet Engine for Propulsion of Aeroplanes at High Speeds" (Twelfth Louis Bleriot Lecture).

Plastics Institute (at the Wellcome Foundation Building, Euston Road, London, N.W.1), at 6.30 p.m.—Mr. S. P. Chambers: "International Competition in the Chemical Industry" (Tenth Annual Lecture).

Antiquarian Horological Society (at the Science Museum, South Kensington, London, S.W.7), at 7 p.m.—Mr. W. J. Gazeley: "The Lever Escapement".

Royal Institute of Chemistry (joint meeting with the Chelsea College of Science and Technology Chemical Society, at the Chelsea College of Science and Technology, Manresa Road, London, S.W.3), at 7 p.m.—Prof. E. D. Hughes, F.R.S.: "Reaction Mechanisms".

Chemical Society (at Burlington House, Piccadilly, London, W.1), at 7.30 p.m.—Sir Eric Rideal, F.R.S.: Irving Langmuir Memorial Lecture.

Friday, March 13

Institution of Mechanical Engineers (in conjunction with the British Nuclear Energy Conference, at Central Hall, Westminster, London, S.W.1), at 9.30 a.m.—Lecture Symposium on the Geneva Conference.

British Psychological Society, Occupational Psychology Section (in the Department of Psychology, Birkbeck College, Malet Street, London, W.C.1), at 1 p.m.—Mr. A. K. Rice: "Systems of Organisation".

Royal Astronomical Society (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Papers by Dr. O. J. Eggen, Dr. A. R. Sandage and Prof. F. Hoyle, F.R.S. Dr. H. E. Butler: "Possibilities of Astronomical Research with British Rockets".

Royal Institution (at 21 Albemarle Street, London, W.1), at 9 p.m.—Dr. H. M. Finniston: "On Bombarding Solids with Neutrons".

Saturday, March 14

British Society for the History of Science (in the Auditorium of the Wellcome Building, Euston Road, London, N.W.1), at 10.15 a.m.—Symposium on "Darwin, Evolution and Modern Life". (Darwin Symposium to commemorate the Centenary of the publication of "The Origin of Species", 1859.)

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Laboratory Steward (over 21 years of age, previous experience in a biological, medical, biochemical or chemical laboratory, and preferably experience in the preparation of biological materials, and in photography) in the Department of Botany—The Registrar, University College, Singleton Park, Swansea (March 14).

Post-Doctoral Fellow in the Department of Organic Chemistry, for work on metabolites of marine micro-organisms—The Registrar, The University, Liverpool (March 14).

Tutor or Lecturer (woman, with special qualifications in either experimental or theoretical physics) in Physics—The Treasurer, Somerville College, Oxford (March 14).

Lecturers (2) (one Grade II and one Grade III) in the Department of Mechanical Engineering—The Registrar and Secretary, The University, Bristol (March 16).

Lecturer (with special qualifications in pure mathematics) in Mathematics—The Registrar (Room 22, O.R.B.), The University, Reading (March 19).

Lecturer (with experience in the use of digital computers and qualified to give lectures in numerical analysis or the principles and details of programming) in the Computing Laboratory—The Secretary of University Court, The University, Glasgow (March 20).

Physicist, Principal grade (with wide experience of hospital physics)—The Clerk to the Governors, St. Thomas's Hospital, London, S.E.1 (March 21).

Lecturer (preferably with experience in the design of electrical plant or control systems) in Electrical Engineering—The Registrar, Queen Mary College (University of London), Mile End Road, London, E.1 (March 23).

Assistant Lecturers (2) in the Department of Zoology—The Registrar, University College of South Wales and Monmouthshire, Cathays Park, Cardiff (March 31).

Chair of Biology in Monash University, Melbourne, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (March 31).

Assistant in Statistics—The Secretary, The University, Aberdeen (April 4).

Junior Research Fellow in the Natural Products Research Unit, Chemistry Department, University College of the West Indies—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (April 4).

Research Fellow (with a Ph.D. degree or equivalent research experience) in the Chemistry Department, for work on absorption from the liquid phase by carbon absorbents, in collaboration with Dr. J. J. Kipling—The Professor of Chemistry, The University, Hull (April 6).

Assistant Physicist (with experience in electronics) at Auckland Hospital, New Zealand, for duties mainly concerned with a linear accelerator—The High Commissioner for New Zealand, New Zealand House, 415 Strand, London, W.C.2 (New Zealand, April 9).

Lecturer in Mathematics—The Secretary, The University, Aberdeen (April 11).

Reader in Agricultural Economics in the Newcastle Division of the University—The Registrar, University Office, 46 North Bailey, Durham (April 11).

Lecturers in Experimental and Theoretical Physics—The Secretary of University Court, The University, Glasgow (April 15).

Senior Lecturer in Biochemistry at the University of Malaya—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (April 15).

Assistant Lecturer or Lecturer (preferably with some experience in radiochemical techniques) in Inorganic Chemistry—The Registrar, The University, Nottingham (April 18).

Curator (with an approved university degree in science or equivalent and some experience in the taxonomy of vertebrates) of Mammals at the National Museum, Melbourne, Australia, to take charge of the mammal collections, undertake field work, conduct research upon mammals, and to assist in such other Museum matters as may be required—The Agent-General for Victoria, Victoria House, Melbourne Place, Strand, London, W.C.2 (April 25).

Assistant Professor (with postgraduate education equivalent to the Ph.D. in plant pathology and related fields) of Plant Pathology in the Department of Plant Science—Head of the Department of Plant Science, University of Alberta, Edmonton, Alberta, Canada (May 1).

Associated Electrical Industries Fellow in the Department of Engineering, for research in any branch of engineering—The Secretary-General of the Faculties, The University, The Old Schools, Cambridge (May 31).

Assistant Director (with a good science degree, preferably with some knowledge of genetics and/or statistics, and also a knowledge of at least two foreign languages) of the Bureau of Animal Breeding and Genetics, King's Buildings, West Mains Road, Edinburgh 9, Scotland—The Secretary, Commonwealth Agricultural Bureaux, Farnham House, Farnham Royal, Bucks (June 14).

John Thompson and Tube Investments Research Scholars (graduates of Sheffield or any other approved university), for research in mechanical engineering—The Registrar, The University, Sheffield (June 20).

Hydrologist (between 23 and 45 years of age, with a degree in civil engineering and at least two years subsequent experience, or a degree in applied science with some direct experience in applied hydrology) in the Ministry of Works, Kenya, for duties which include the measuring of river flows, assessment of flood discharges, rainfall-runoff, studies and assessment of ground-water resources, their recharge and depletion—The Director of Recruitment, Colonial Office, London, S.W.1, quoting BCD.112/7/01/T.

Lecturer (preferably with experience of digital electronic circuit techniques) for teaching and research in Control Engineering, to work with a group concerned with the development of statistical and digital methods in relation to all types of electrical, hydraulic and pneumatic controls—Head of the Electrical Engineering Department, Imperial College, Exhibition Road, London, S.W.7.

Lecturer (with experience in the development of electrical machines, and preferably an interest in combinations of machines and rectifiers for high power outputs) in Electrical Engineering—The Head of the Electrical Engineering Department, Imperial College, Exhibition Road, London, S.W.7.

Master (with a good degree, and preferably a bachelor) to teach Physics to Advanced and Scholarship Level—The Headmaster, Ampleforth College, York.

National Research Council Postdoctoral Fellow in Pathology, Mycology, Physiology or Cytology; and a Postgraduate Fellow for the study of micro-organisms involved in cellulose decomposition—The Head of the Department of Botany, University of Western Ontario, London, Canada.

Physicist (honours graduate), to work on radiation effects in solids—Prof. W. R. Ditchburn, Physics Research Laboratory, The University, Upper Redlands Road, Reading, Berks.

Second Technician (with A.I.M.L.T. or National Certificate in Chemistry or equivalent qualifications and experience) in the Cardiac Laboratory, for biochemical investigations—The Director of Pathology, Royal South Hants Hospital, Southampton.

Senior Lecturer or Lecturer (graduate in pharmacy, and actively interested in research) in Pharmacology in the Department of Pharmacy—The Registrar, Bradford Institute of Technology, Bradford 7.

Senior Lecturer (with a university degree or equivalent and a sound theoretical and applied knowledge of electronics) in Medical Engineering (Electronics)—The Dean, Postgraduate Medical School of London, Ducane Road, London, W.12.

Senior Scientific Officers, Scientific Officers and Research Fellows (with a first- or second-class honours degree, an interest in high-energy plasma physics and preferably experience with microwave techniques) in a new group investigating thermonuclear experiments utilizing the injection of pre-accelerated particles into magnetic fields with mirror geometry—The Senior Recruitment Officer, Atomic Weapons Research Establishment, Aldermaston, Berkshire, quoting Ref. 2177/34.

University Demonstrator in Biochemistry—The Administrator, Department of Biochemistry, The University, South Parks Road, Oxford.

Zoologist (with postgraduate training in ethology), to undertake research into the feeding behaviour of wildfowl—The Assistant Director (Research), The Wildfowl Trust, Slimbridge, Gloucestershire.

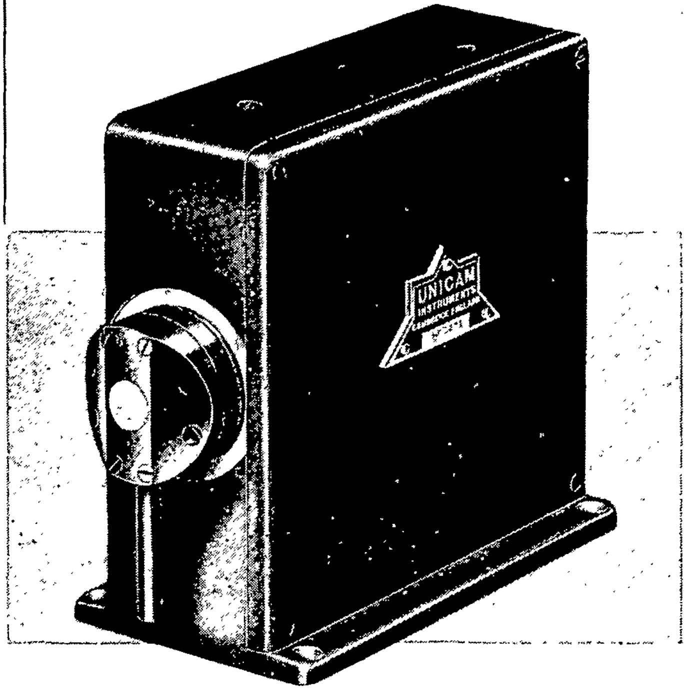
An
INFRARED DETECTOR

sensitive
from
Visible
to
Microwaves



The operation of the Golay Detector is based upon the expansion of a gas of low thermal conductivity in contact with a non-selective heat absorbing membrane. The cell in which the gas (normally Xenon) is sealed has at one end a mirror membrane operating in a photoelectric amplifier system in such a way that the light intensity at the photocell varies directly with the gas expansion.

One of the major advantages of this system is a uniform sensitivity over a wide range of wavelengths. With suitable window material the Detector can be used to measure radiation intensities from visible light out to the microwave region. The adjoining table shows recommended window materials for specific wavelength regions.

The Detector can be delivered from stock with the following windows — KBr, Quartz, KRS-5, CsBr.

We shall be pleased to quote for alternative windows, for the Detector alone or for the full equipment including electronic and chopper units.

TABLE OF WINDOW MATERIALS

Material	Approximate useful wavelength limits
KBr	from visible to 26 μ — 27 μ.
CsBr	„ „ „ 35 μ — 40 μ.
CsI	„ „ „ 45 μ — 50 μ.
Quartz (0.25 mm thick)	„ „ „ 3.5 μ and from 45-50 μ to microwaves.
*Arsenic trisulphide	„ „ „ 10 μ.
*KRS-5	„ „ „ 35 μ.

*These two salts are non-hygroscopic but introduce some energy losses.

RESEARCH IN THE UNDER-DEVELOPED TERRITORIES

"COLONIAL Research" continues to expand, although the report for 1957–58* is only some 25 pages larger than that for 1956–57. Apart from the brief annual report on Colonial research from the Colonial Research Council, it contains the thirteenth annual reports of the Committee for Colonial Agricultural, Animal Health and Forestry Research, the Colonial Medical Research Committee, the fourteenth annual report of the Colonial Social Science Research Council, the eleventh annual reports of the Colonial Economic Research Committee and the Colonial Pesticides Research Committee, the fifth annual report of the Colonial Products Council, the third annual report of the Colonial Road Research Committee and reports from the Colonial Fisheries Advisory Committee, the Tsetse Fly and Trypanosomiasis Committee and the Director of the Anti-Locust Research Centre covering the same period. There is also a report dealing with research matters such as building and housing research, the Falkland Islands Dependencies Survey, geodetic and topographical surveys, geological surveys, industrial and engineering research, and meteorology and water pollution research which are not covered by the accompanying reports of the specialist advisory bodies.

Some of these reports include as appendixes reports from Colonial or overseas bodies such as the East African Institute of Social Research, the Nigerian Institute of Social and Economic Research, the Rhodes–Livingstone Institute and the Institute of Social and Economic Research in the University College of the West Indies. There is also fully displayed the way in which the work in some fields can be linked with that of institutions in Britain, such as the Commonwealth Institute of Entomology, the Commonwealth Mycological Institute, Rothamsted Experimental Station, the Long Ashton Research Station, the Field Station at Silwood Park of the Imperial College of Science and Technology, the Unit of Experimental Agronomy of the Agricultural Research Council, and the Building Research Station of the Department of Scientific and Industrial Research. Nor is the impressive list of institutions mentioned in this publication exhaustive, for the recent report of the Nature Conservancy refers to help given by that body, notably in relation to a proposal to establish in Kenya a unit for research on wild fauna, and to the solution of controversy in Tanganyika over the reconciliation of practical problems and the scientific objectives of conservation in the Serengeti plains and the Crater Highlands. The Government's revised proposals here were closely guided by an ecological survey of the area undertaken by Prof. W. H. Pearsall on behalf of the Conservancy.

"Colonial Research 1957–58" thus provides an impressive, but even so, not exhaustive, picture of the effort which Britain is putting into research in the under-developed countries of the Commonwealth; and although the magnitude of that effort, either in terms of finance or of man-power, is not discussed directly, it is apparent that the demand for trained man-power is likely to have a far greater effect on Britain's limited resources than the demands of the under-developed countries for technical assistance have had in the United States, where it has already been cited as a contributory factor in the man-power shortage. The twenty-six new appointments made during the year brought the total complement of the Research Branch of the Oversea Service to 202 officers, and besides two continuing research fellowships, a further eight research studentships were awarded. Recruitment for moderately senior research posts continued to be difficult, but the Committee for Colonial Agricultural, Animal Health and Forestry Research reported more candidates for junior posts and awarded seven research studentships, bringing the total of research students to fourteen. The staff of the Colonial Section of the Road Research Laboratory reached sixteen during the year, but there are still nine vacancies. The staff of the geodetic and topographical surveys at the end of March 1958 was 437, and the overseas territories (excluding Malaya and Ghana) had 207 geologists, geophysicists and chemists on geological survey, with about twenty vacancies still existing, while meteorological work also was hampered by shortage of staff. It should be remembered, moreover, that the United Kingdom has already provided 317 experts under the Technical Co-operation Scheme of the Colombo Plan, an increase of 54 in 1957–58.

Apart from these items, "Colonial Research" gives no indication of the magnitude of the demand for man-power. Information on finance is equally sketchy. Expenditure under the Colonial Research Council during the year was £1,330,641 compared with £1,534,746 in 1956–57 and with £1,575,000 in the 1958–59 estimates. Colonial Development and Welfare Research Schemes made during the year brought the total allotted to such schemes under the Acts since 1940 to more than £18·5 million, of which £13·5 million has already been disbursed. Besides this, however, the United Kingdom has allocated since 1951 some £123·25 million for capital and technical assistance in the centres of south and south-east Asia under the Colombo Plan, of which £92·5 million had been disbursed by June 30, 1958

---

* Colonial Research 1957–1958: Reports of the Colonial Research Council; Committee for Colonial Agricultural, Animal Health and Forestry Research; Colonial Economic Research Committee; Colonial Fisheries Advisory Committee; Colonial Medical Research Committee; Colonial Pesticides Research Committee; Colonial Products Council; Colonial Road Research Committee; Colonial Social Science Research Council; Tsetse Fly and Trypanosomiasis Committee; Director, Anti-Locust Research Centre; and Research Matters not covered by the above Reports of the Specialist Advisory Bodies. Pp. 347. (Cmnd. 591.) (London: H.M. Stationery Office, 1958.) 14s. 6d. net.

(£3·71 million of this was for the Technical Co-operation Scheme). About 35 per cent of the gross allocation from Colonial Development and Welfare Funds has been for agricultural, animal health and forestry schemes, 16 per cent for medical research, 10 per cent for fisheries research, 9 per cent for tsetse and trypanosomiasis research, 8 per cent for social science and economic research, 8 per cent for pesticides research, 5 per cent for research sponsored by the Colonial Products Council, 3 per cent for anti-locust research and 6 per cent for miscellaneous schemes. About 38 per cent has been for schemes to benefit the East African territories, 16 per cent for the West African group, 12 per cent for the West Indian Colonies, British Guiana and British Honduras, 8 per cent for the south-east Asian territories and Hong Kong and 5 per cent for the central African territories.

Apart from this indication of the broad distribution of the research effort, the report really shows little of its relation to Britain's own effort. There is, however, a significant comment in the report on fisheries research during 1957–58. The Colonial Fisheries Advisory Committee points out that, with the closure of the West African and the Singapore fishery research stations, both regional and both considerably endowed from Colonial Development and Welfare Funds, Colonial fishery research appears to have entered a new phase, and that for some time to come fundamental research will be regarded in some territories as beyond their means. More and more research institutes will be asked to concentrate on applied research.

The Colonial Fisheries Advisory Committee recognizes the situation, and it is watching with interest a joint research and development scheme in Sierra Leone; but the difficulty should be considered in the wider context of an observation to be found in the recent report of the Secretary-General to the ninth meeting of the Scientific Council for Africa South of the Sahara. Here, too, is recognized the increasing importance of local factors; but the importance of basic research in a developing continent is firmly stressed, and while activities in the inter-African field are intended to serve the interests of Africa, in doing so the fullest support must be given to European research workers, institutes and technical departments. For a long time to come Europe will provide most of the scientific and technical assistance needed in Africa.

Rightly the report directs attention to the way in which the Scientific Council for Africa South of the Sahara is qualified to assist this evolution. Its members have been trained in the highest European disciplines and are eminent scientists who have devoted much of their lives to research. At the same time, they are all Africans, by adoption if not by birth, for their work and experience, their life itself, have for many years been in the service of Africa. The Council's meetings are held in Africa and its discussions and recommendations during the past nine years have had the sole objective of enabling science to assist the development of Africa.

There are already close relations between the Scientific Council and those engaged in Colonial research under the auspices of the various advisory research bodies the reports of which are collected in "Colonial Research"—for example, those concerned with fisheries or with social science; and the most cursory reading of either "Colonial Research" or the report of the Scientific Council for Africa South of the Sahara will show how much of the work is interrelated. It is indeed in this context that Britain's own effort in Colonial research is most appropriately considered. Valuable as the detailed work done by British and other European staff still is, it must be taken over more and more by trained men and women in the territory served as educational programmes develop. Meanwhile, however, and for years to come, the Colonial and similar territories will depend on assistance from the United Kingdom and other Colombo Plan countries, and from the specialized agencies of the United Nations; and the shortage of trained man-power throughout the world makes it imperative that there should be no hindrances to the efficient use of whatever scientific and technical man-power can be placed at the service of the under-developed areas.

This accentuates the importance of establishing the political and economic conditions, as well as the scientific and administrative means, for effective co-operation, and lends force to the contention of the Scientific Council for Africa South of the Sahara that it is essential to maintain an advisory group of highly qualified scientists, representing the various disciplines with which the Commission for Technical Co-operation in Africa South of the Sahara and the responsible Governments are concerned. Only as co-operation is promoted effectively at the highest level can we expect to ensure both the conditions for efficient scientific and technical work, and the removal of the obstacles that could, if allowed to remain, engender frustration and waste of effort, if not lead to real misunderstanding. The establishment last year of the Foundation for Mutual Assistance in Africa, stimulated largely by the success of the technical assistance programme under the Colombo Plan, both indicates the value of such co-operation and should in due course encourage the territories to provide their own scientific and technical experts, though the immediate effect may well be, by facilitating exchange, to increase the amount of technical assistance.

It is difficult at the present time to over-stress the importance of these matters not simply to science and technology but also to the economic future of Britain and the Western world. Sir Harold Hartley, in his Fawley Lecture last November, touched on its bearing on Britain's economic future and the challenge to industry to assist in developing the less-industrialized countries. He stressed the importance of careful planning, and indicated the extent of the demand for help which could reach even one company, as well as the difficulties which economic conditions and a narrow nationalist outlook could cause. In another context, Sir Oliver Franks, in his chairman's address to Lloyds Bank, Ltd., referred to the dangers of allowing the gap between rich and poor countries to widen still further and to the policies that should be pursued to give effect to the undertaking to help the under-developed countries given at Montreal.

As Sir Oliver Franks points out, the under-developed countries cannot embark upon development programmes regardless of their own resources, and then demand that the industrial countries should underwrite them to any extent the under-developed countries wish. Nor is it reasonable to expect the under-developed countries, unguided, at this stage, to choose the right priorities in research, or to maintain a sound balance between fundamental and applied research, even if they could finance unaided the necessary programmes. It is at this stage, for years to come, that co-operation at the international level will be imperative, both in planning the programmes and in ensuring that the under-developed countries secure the maximum return from whatever resources in man-power, equipment and finance can be placed at their disposal through Colonial Development and Welfare Funds, the Colombo Plan, or the technical assistance programme of the United Nations.

There is still work to be done in creating the political conditions in which technical assistance is most effectively given, and much of the value of "Colonial Research 1957–58" lies in the conspectus it provides of the character and magnitude of Britain's effort in this field. It is important that this should be fully appreciated, particularly, in spite of Mr. Nixon's tribute to Britain's enlightened work, in view of the tendency to misrepresent colonialism. Some amplification of the picture as given in this report of the magnitude of Britain's effort in Colonial research in terms of man-power and finance, in comparison with the total research effort of the country and with the contribution of other countries to overseas research and development, might well be worth while including in future reports from the Colonial Research Council.

There is yet another aspect to consider. Under the Technical Co-operation Scheme of the Colombo Plan, the United Kingdom Government has provided the Pakistan and Ceylon Councils of Scientific and Industrial Research with scientific equipment for their laboratories at Karachi (£83,500) and Colombo (£80,000). Smaller sums have gone to the Plant Virus Research Laboratory, Manila, to the Soil Science Laboratory, Cambodia, and to the Agricultural Research Station, Kachim State, Burma. Such gifts all help to create the conditions in which effective scientific work is carried out, and the two thousand-odd trainees who have already been welcomed to the United Kingdom also help, on their return to their own countries, to promote the appropriate climate for research and development.

An even more important factor, however, may well be the conditions which already exist in the research institutions overseas, in the Colonial territories themselves and elsewhere. The standards maintained in such institutions must affect profoundly the quality of scientific and technical work in the territories they serve—for years to come and not simply while the work may continue to be carried out largely by scientists and technicians from Britain and other Western countries. The importance of the Colonial Research Council and of the various specialist advisory bodies, as well as of such bodies as the Scientific Council for Africa South of the Sahara, in this respect is not easily over-stressed and both from the reports on Colonial research and that of the Scientific Council for Africa, it appears that they are well aware of their responsibility. Nevertheless, "Colonial Research 1957–58" has a significance in this connexion which is not always appreciated. For many scientific workers engaged in research overseas, sometimes in comparative isolation, with slender opportunities for meeting their fellows, often in difficult or trying conditions, both technically and socially, the conspectus of scientific work displayed in the pages of this report represents one of the few opportunities which their work has of receiving attention. It is indeed a record of which British scientists have every right to be proud, and it might be worth while, both from Britain's point of view and that of recruitment to the Oversea Scientific Service, for closer consideration to be given to the possibility of giving more effective publicity to some at least of the many detailed achievements recorded in these three hundred pages.

QUANTUM MECHANICS IN ITS FOURTH DECADE

Quantum Mechanics

By Prof. H. A. Kramers. (Series in Physics.) Translated by D. ter Haar. Pp. xvi+496. (Amsterdam: North-Holland Publishing Company; New York: Interscience Publishers, Inc., 1957.) 45 guilders.

Quantum Mechanics

Non-Relativistic Theory. By L. D. Landau and E. M. Lifshitz. Translated from the Russian by J. B. Sykes and J. S. Bell. (Course of Theoretical Physics, Vol. 3.) Pp. xii+515. (London: Pergamon Press, 1958.) 80*s*. net.

Quantum Mechanics

By Dr. F. Mandl. Second edition. Pp. x+267. (London: Butterworths Scientific Publications; New York: Academic Press, Inc., 1957.) 35*s*.; 7 dollars.

Angular Momentum in Quantum Mechanics

By A. R. Edmonds. (Investigations in Physics, Vol. 4.) Pp. viii+146. (Princeton, N.J.: Princeton University Press; London: Oxford University Press, 1957.) 30*s*. net

Elementary Theory of Angular Momentum

By M. E. Rose. (Structure of Matter Series.) Pp. x+248. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1957.) 80*s*. net.

THIRTY-FOUR years ago, in 1925, quantum mechanics was born. The preceding twenty-five years had seen a gradual assembly of facts and a development of concepts which revealed startlingly the inadequacy of classical physics for describing atomic phenomena, but not until 1925 could it be claimed that the new situation was understood. The great discoveries, associated primarily with the names of Heisenberg and Schrödinger, gave us this understanding in what in retrospect appears as one brilliant flash of insight. In fact, the period just after 1925 was one of intense theoretical development, to which many individuals contributed, and it was five or so years before quantum mechanics in the shape now familiar was completely revealed. The men who took part in this development have since stood out as the great figures of modern theoretical physics, and they and their immediate pupils have dominated the developments of the subject until very recently. Some of these men, indeed, still remain in the forefront of research. However, to-day a new generation of theoretical physicists is taking over, for which the nineteen-twenties are a chapter of history, and it is for these and their pupils that new text-books and monographs must cater. The mere passage of time must inevitably change a student's attitude to a subject of study. If one has grown up trained to think entirely in the language of classical physics, the transition to quantal thinking cannot but be a painful process, and in learning quantum theory one's main preoccupation will inevitably be with the 'paradoxes' it introduces, with the reconciliation of the new concepts and the old. But, just as the learning of a new language in infancy is a process entirely different from that of learning it in adult life, so the modern student can and should be enabled to acquire a working knowledge of quantum mechanics without having to live through the labour pains of its creators. True, one must insist on the fact that the very formulation of quantum mechanics requires the prior establishment of classical physics, but the initial teaching of classical physics can and should be adapted from the start to the quantal generalization to come, and quantum theory itself can be introduced with much less of a retrospective attitude. Many of the questions of the detailed relationship to classical theory may be left to a more advanced stage of development, just as grammar forms a later stage in the teaching of a language to a child.

To relegate to a secondary position the deeper studies of the foundations of quantum theory may seem unsound to many, but the reviewer feels that if to-day one's pupils are to be guided to the forefront of research in the limited time available for their training (and this time is limited not primarily by the educational system but even more by the inescapable fact that the peak in creative ability is so often attained at a very early age) changes in the directions suggested are inevitable. If we older generation of teachers do not make this re-orientation, our successors will certainly do so.

Of the five books the reviewing of which has given rise to these thoughts, the first, a translation of H. A. Kramers's classic contributions to the "Hand- und Jahr-buch der chemischen Physik", appearing as a single book under the title "Quantum Mechanics", is an example of the traditional exposition of the subject. In its class this work is undoubtedly one of the greatest. Kramers's part in the developments of the 'twenties was a more important one than is perhaps realized nowadays, and he was also one of the greatest of teachers. (To him we owe among so many other things the concept of 'renormalization' which dominated developments ten years ago.) The translator and publishers deserve nothing but praise for making this masterpiece available to English-speaking readers. Nevertheless, it is not a text-book one would nowadays recommend for initial study. In particular the reviewer cannot agree that the first five chapters, which also have been issued separately under the title "Foundations of Quantum Theory", are "extremely suitable as a text-book for college purposes" as claimed in the publishers' announcement. These chapters, while providing an admirable, one may say inspired, analysis of the relation of classical and quantal theory, do not even take the development as far as the introduction of spin.

A very different spirit pervades the volume on "Quantum Mechanics (Non-Relativistic Theory)", which forms part of the nine-volume course of theoretical physics by Landau and Lifshitz. This is again a translation, and as in the case of the preceding work the reviewer is disposed to praise translators and publishers wholeheartedly, passing over the quite minor blemishes noted in both works. The Landau-Lifshitz series is undoubtedly a worthy modern successor to the classic German series of Planck and of Sommerfeld and it is modern in precisely the sense called for in the introductory remarks. "Quantum Mechanics" is not the ultimate volume of the series, but the third. Only (classical) "Mechanics" and "The Classical Theory of Fields" are designed to precede it and, with "Statistical Physics" to round off the 'basic' disciplines, such 'derived' subjects as hydrodynamics, elasticity and electrodynamics of continuous media follow in later volumes. This conception seems admirable, and to judge from the volume in hand the execution matches the conception. To the serious student of theoretical physics no better text-book could be recommended, even though the Russian original appeared in 1947 so that certain recent developments (for example, 'effective range' theory in scattering) are inevitably missing and the emphasis on molecular theory is perhaps rather greater than one would desire to-day.

The third book on general quantum mechanics is the only original English publication of the three, Mandl's "Quantum Mechanics". This is a much less ambitious work, much shorter, more elementary and, let us be grateful, lower in price. We are told that the book originated in a course of quantum theory given to 'experimentalists' at Harwell in 1952 and one can see from the book why the course was a success. The author does a splendid job in making the ideas and methods of quantum theory clear with the minimum of mathematical sophistication. However, it seems to the reviewer that the very fact that such courses are needed in such a specialized centre as Harwell casts a sad reflexion on our British methods of training physicists. While in the Soviet Union it seems to be natural to place quantum mechanics side by side with classical mechanics and electrodynamics as a basic discipline in physics, here we have brought up the majority of our own physicists as 'experimenters' whose training, almost by definition, debars them from acquiring the language and tools of this branch of their subject at an early stage, so that they must seek enlightenment late in their careers in specially designed courses and in books in which mathematical argument of the slightest complication must be laboriously spelled out. How much better if Mandl's fine little book need never have been written !

A sign of the dominant role of quantum mechanics in modern physics is the need for specialized monographs on particular topics in the field. The two volumes on "Angular Momentum in Quantum Mechanics" by Edmonds and "Elementary Theory of

Angular Momentum'' by Rose deal with one and the same such special topic. It is one that is included to some extent in any quantum mechanics text-book, but it has special importance in modern work, as these two monographs demonstrate, and is capable of being much expanded instructively and usefully. The difference between the two versions, which is considerable, seems to the reviewer to be just that in Edmonds's work the instructive character strikes one most, in Rose's the useful side. The latter author is himself responsible for a great many important applications of the methods here described, and in this monograph he has succeeded in bringing together in a unified form the mathematical theory underlying these methods as well as an extensive array of its applications, so that to future workers in the field the monograph will undoubtedly serve as a most useful manual. Edmonds in his shorter book lays relatively more emphasis on the formal and conceptual structure of the theory of angular momentum and his book is somewhat more of the nature of an expanded chapter of a text-book on general quantum mechanics. In fact, the Landau–Lifshitz volume contains an admirable chapter on this topic and the fortunate student who learns his quantum mechanics from that work will find himself fully equipped to master the further developments of this monograph. Edmonds's book will undoubtedly be appreciated by workers in the field not least because of the author's commendable policy of listing systematically and fully the great variety of symbols which, unfortunately, are in use to denote the various group theoretical coefficients in which the subject abounds.

N. Kemmer

PHYSICS FOR THE ELECTRICAL ENGINEER

Physical Basis for Electrical Engineering

By Prof. Thomas L. Martin, Jr. Pp. xii+410. (London: Macmillan and Co., Ltd., 1958.) 30*s.* net.

MOST engineers who have been out of college more than ten years, and many teachers of electrical engineering as well, will find food for thought in this book. Their first reaction may well be of dismay that it is now proposed to teach in a first course in electrical engineering (so the author suggests in his preface) a great deal of physics with which they themselves have only a slight acquaintance. After dismissing in the first two chapters the electromagnetic field *in vacuo* (from "Vectors and Scalars" via Poisson's and Laplace's equation to the Lorentz transformations and electromagnetic waves) the book goes on to describe modern ideas of atomic and nuclear structure, the structure of metals and of semiconductors, practical semiconductor devices, vacuum and gas tubes, dielectrics (including ferroelectrics) and the theory of magnetic materials.

Closer examination reveals the very real dilemma of the teacher of electrical engineering to-day. Wave-mechanics is carefully excluded from the book, and 'degeneracy' is not to be found in the index. Perhaps this is why the definition of Fermi-level in the text appears so inadequate that it has been supplemented by another definition in an appendix. But should one try to teach all these experimental phenomena, yet firmly refuse to dig in to the solid foundations? If there is not time to teach a student both physics and electrical engineering thoroughly, how valuable is a superficial account of the physics? Yet this is only the physical basis for to-day's electrical engineering—soon it will be yesterday's electrical engineering. (There is nothing here to help us understand the maser or the use of the concept of entropy in communication theory, for example.)

The extent of the work involved in writing a book which covers so wide a field as this book is not to be belittled, especially as it is fairly liberally supplied with references to original work to enable the reader to pursue his study of any particular point. But one does not need to be a specialist to pick holes in details. Among the dozen or so points noted in a quick reading, there is a suggestion on p. 185 that conduction in an intrinsic semiconductor commences "at some fairly definite temperature", and on p. 208 we are told there are semiconductor diodes and varistors and transistors, but on p. 210 "semiconductor diodes or varistors" appear to be one and the same. The treatment of space-charge-limited thermionic currents is not happy, and it seems clear that the author has neither read Langmuir's classic papers nor himself tried to measure accurately a 3/2-law characteristic.

To sum up, this book is a bold attempt to provide engineering students with knowledge of what the author considers to be the relevant branches of physics; but even the elementary student deserves a clear and accurate treatment of the topics, and there are some passages which are not up to this standard.

D. A. Bell

ANIMAL ECOLOGY

Animal Ecology

Aims and Methods. By A. Macfadyen. (Zoology Series.) Pp. xx+264+6 plates. (London: Sir Isaac Pitman and Sons, Ltd., 1957.) 40*s.* net.

THIS book is difficult to read owing to the use of multitudinous sub-headings which destroy the continuity of the chapters. Partly as a result of this, the treatment of individual subjects tends to be too slight: as soon as some topic begins to grow interesting, it stops short. It would have been better to have selected fewer subjects and dealt with them more thoroughly. Parts of the book are little more than a catalogue. On the other hand, the numerous references which this involves are certainly valuable, though their use is greatly impeded by the unfortunate device of splitting them up into fourteen separate lists at the ends of chapters instead of bringing them together to form a single corpus of literature.

The account of collecting methods (Chapter 6) is very brief and incomplete. Among other omissions, the mercury-vapour trap which has so much revolutionized our knowledge of the distribution and habitats of insects, especially the Lepidoptera, is not mentioned. The description of marking techniques is also too curtailed to be of use. It is condensed into a small paragraph on p. 89, and no mention is made of the exciting possibilities opened up by marking with radioactive materials (there is brief mention of their use in another connexion). The mathematical procedures to be used in marking – release – recapture work, which might certainly be expected in a book which sets out to include methods, are scarcely touched upon. One has the impression that the chapter on "Biocoenology" could advantageously be replaced by one on ecological barriers, which are scarcely mentioned.

Yet though too many minor topics have been chosen, some important major ones are omitted. The ecology of marine and estuarine animals and communities, and the methods of studying them, are insufficiently described, while the vast contributions of ecology to the study of evolution are relegated to three pages. The theory of Sewell Wright is said to fall outside the scope of the book, though it is not clear why. It is mentioned in two brief paragraphs, in which it is said that "the existence of small isolated populations provides unusual opportunities for the rapid evolution of new sub-species bearing characteristics which would not be tolerated in the more normal conditions of larger populations among which natural selection is in full operation". It should also be pointed out that such conditions provide unusual opportunities for solution by natural selection. No attempt is made to include the great subject of ecological genetics, though we are told (p. 13) that "the genetic structure of a population in the wild is constantly changing, for it is the result of an equilibrium between mutation rate of recessive factors and selective elimination of unsuccessful individuals". It is very surprising that such a statement, overlooking polygenic variation and polymorphism, could be made in a modern book.

The captions on Plate 2 are interchanged, as are the two lower captions on Plates 5 and 6. The price seems high for a book of moderate size containing eleven tables, nineteen text figures, six black-and-white, and no coloured, plates.

E. B. Ford

STUDY OF EARTHQUAKES

Elementary Seismology

By Charles F. Richter. Pp. viii+768. (San Francisco, Calif.: W. H. Freeman and Company; London: Bailey Bros. and Swinfen, Ltd., 1958.) 12 dollars.

At the present time, when geophysical methods and theories are permeating every branch of geology and geotectonics and effecting a gradual revolution in geological thinking, the appearance of a book which helps this process is an important event. Sound reasoning, likewise, in geophysics can only stem from a sound well-balanced basic knowledge of classical geology, physics and mathematics, ably synthesized as in the book under review.

This book is divided into three parts. Part 1, entitled "The Nature and Observation of Earthquakes", contains twenty-four chapters on 394 pages. The first fourteen chapters largely concern field observations of earthquake effects, the background for these chapters being geological and non-mathematical. Chapter 15 contains an elementary discussion of seismograph theory and practice, and there follow chapters on elastic waves, deep-focus earthquakes, and the reduction of instrumental observations. The final two chapters are on microseisms and on earthquake risk and protective measures to be taken in areas likely to be subjected to earthquakes.

Part 2 of the book is entitled "The Geography and Geology of Earthquakes" and contains nine chapters on 246 pages. The author of the book for many years has taken a very great interest in this work, and being thus exceptionally well qualified for the writing, cannot fail to be informative and stimulating. After an introductory chapter he sets off immediately into a discussion of arc and block tectonics, and follows this up with descriptions of the geotectonics and earthquake phenomena of California, New Zealand, Japan and Formosa. Most of these regions have been studied at first hand in the field by Dr. Richter, as also through the medium of instrumental data and literature. The part ends with chapters on the tectonic earthquakes of other regions; compressions and dilations; and on seismology in the U.S.S.R. Since the days of Prince B. Galitzin, Russia has been renowned for her students of seismology, and her sons to-day are worthy successors of this heritage (the late Dr. G. A. Gamburtsev; and Dr. E. T. Savarensky, Dr. D. P. Kirnos, Dr. V. I. Keylis-Borok, Dr. E. W. Karus and others).

Part 3 of the book, which contains seventeen appendixes on 100 pages, and is somewhat more advanced than Parts 1 and 2, being mostly composed of items useful in a seismological laboratory such as a list of seismological observatories, a table of angles of incidence of elastic waves in the Earth and related quantities for shallow-focus earthquakes; the refraction and reflexion of earthquake waves including the Zoeppritz equations; transit-time tables and magnitude charts. In addition, there are items frequently requested by the general public such as lists of large earthquakes, a chronology of historically important events and discoveries in seismology; and an appendix on earthquake-resistant construction.

As will be seen from the foregoing statements, the book is exceptionally well balanced, the proper weight having been given to field observations and geology. Within the limits set by the author it is comprehensive and even encyclopædic in its contents, being a masterpiece of selection and compression as only a practical seismologist and lively, experienced teacher could have accomplished. Since the book is so up-to-the-minute in its contents, however, one might have liked to see reference to recent experimental work on seismographs such as is being conducted at Stuttgart, Zürich and elsewhere—though perhaps the author includes this work in the list (on p. iv) of material abbreviated. However, there are very good lists of selected references by which anyone interested may pursue the studies so well begun.

The author, Prof. Charles F. Richter, is professor of seismology in the California Institute of Technology in Pasadena, California, where he has also worked for many years in the seismological laboratory with Prof. B. Gutenberg, Dr. H. Benioff and others. He is joint author with Dr. Gutenberg of the book entitled "The Seismicity of the Earth", and is an originator of the instrumental earthquake magnitude scale. For many years also Prof. Richter has been responsible for regular bulletins on local and distant earthquakes.

This book developed from a lecture course organized particularly for students of geology who do not intend to specialize in seismology or geophysics. Every geological library, and every geological student who can afford it, should get a copy of this book most opportunely published during the International Geophysical Year. It is lavishly illustrated and produced, and the printing, format and binding are all of the highest quality. The book is recommended not only to students of geology, but also to engineers and engineering students, applied mathematicians as a source book of data and ideas for problems, and to all others interested in seismology and the physics of the Earth.

Ernest Tillotson

Proceedings of the Rehovoth Conference on Nuclear Structure held at the Weizmann Institute of Science, Rehovoth

September 8–14, 1957, under the auspices of the International Union of Pure and Applied Physics (IUPAP). Edited by Dr. H. J. Lipkin. (Series in Physics.) Pp. xvi + 614. (Amsterdam: North-Holland Publishing Company; New York: Interscience Publishers, Inc., 1958.) 45 guilders.

THE Rehovoth conference of September 1957 will long be remembered by many who attended it, if only because it was their first opportunity to visit the young and fascinating State of Israel. Apart from that, the conference itself marks a certain stage of development of nuclear physics, a stage at which one feels that a qualitative and even semi-quantitative understanding of the structure of complex nuclei has been reached, and one beyond which must inevitably follow a period of consolidation. There is, in fact, some justification for the sentiment, sometimes expressed, that nothing much has happened in low-energy nuclear physics since the Rehovoth conference. There is, therefore, every justification for the appearance in print of the Proceedings of the conference provided in this handsome volume. The editor has been to great trouble to collate and edit the various communications, long and short, and has even included some carefully edited discussion. The sessions dealt with the shell model and the collective model and their foundations, group-theoretical methods in nuclear spectroscopy (including a beautiful introduction to the concept of seniority by Prof. Racah, who has contributed so much to the techniques of theoretical nuclear physics), electromagnetic properties of nuclei, beta-decay and parity violation, angular correlations in external fields, the instruments of nuclear spectroscopy, and the measurement of short life-times. A final section of the volume includes the *Daily Bulletin* of the Conference, which parodied and commented upon the actual proceedings with such delightful wit. In this permanent record of a memorable occasion the publishers have maintained their customary high standards of printing and presentation. B. H. FLOWERS

Physical and Azeotropic Data

Hydrocarbons and Sulphur Compounds boiling below 200° C. By G. Claxton. Pp. v + 146. (London: The National Benzole and Allied Products Association (N.B.A.), 1958.) 42*s*.

THE first part of this book gives the boiling points and densities of nearly 1,450 hydrocarbons and 190 organic sulphur compounds, together with the refractive indices of most of the substances listed and, in a few cases, melting points.

The second part describes the behaviour on boiling of about 1,000 binary, 90 ternary and three quaternary mixtures, azeotropic and otherwise. One component of every mixture is selected from twelve hydrocarbons and two sulphur compounds which are main constituents or impurities in coal tar benzoles. It is surprising, however, to find the benzene/ethanol azeotrope omitted from the list.

The first nineteen pages comprise a detailed explanation of the unusual system of nomenclature and classification used in the tables. These pages must be given careful study before the tables can be used, and the reader is not assisted by the incorrect printing of the four structural formulæ in Figs. 4 and 6, pp. 10–11. I would have preferred to see the standard nomenclature of the Chemical Society used in the book; the system is already widely known and leads generally to less cumbersome names than does that favoured by the author, and the reader would be spared the trouble of learning another system for which he will find no other use.

A few misprints occur, but the book should prove useful to all who use distillation for analytical or preparative separations and do not wish to use a more comprehensive work such as L. H. Horsley's "Azeotropic Data". B. A. ROSE

The True Book about Insects

By John Clegg. (True Book Series.) Pp. 144. (London: Frederick Muller, Ltd., 1957.) 7*s*. 6*d*. net.

THIS is not another book on identification, but one bringing together information—often to be found only in specialist or out-of-the-way works—on many of the fascinating aspects of insect life.

It describes briefly the general structure of insects and how they grow, with chapters on flight, respiration, the senses of sight, smell and hearing, on feeding, colouring and camouflage. There are interesting accounts of such subjects as plant galls, with life-histories of some of the insects concerned; life in water, with its special problems of breathing and movement; the nuisance to man caused by insects which feed on his crops or transmit diseases, and the remarkable ways of the social bees, wasps, ants and termites. A chapter is included on the use of insecticides in the struggle against pests, with mention of some of the ventures in biological control. Illustrations are good line drawings, and there is a short list of books for further reference.

The author has chosen examples for his text from well-known insects from overseas as well as Britain, and his simply written and enthusiastic account will make a good introduction for the young student of entomology. B. D. MORETON

Perkin Centenary—London

100 Years of Synthetic Dyestuffs. (Supplement No. 1 to *Tetrahedron*.) Pp. xii + 136 + 8 plates. (London and New York: Pergamon Press, 1958.) 42*s*. net.

THIS book, to which Sir Robert Robinson contributes a foreword, provides a permanent record of the proceedings of the Perkin centenary celebrations. Besides the four Perkin centenary lectures, by Prof. John Read, Mr. C. Paine, Mr. J. G. Evans, and Sir Alexander Todd, it includes the speeches made at the Perkin banquet, details of the committees which planned and organized the celebrations, and the final financial report of the Perkin Centenary Fund, with a list of contributors to it. There are some interesting plates of Perkin himself, the Royal College of Chemistry, Hofmann and his students and the Greenford Green works. Prof. J. Read has put us further in his debt by appending to his own vivid survey of the life and work of Perkin references to some other papers on Perkin published at the time of the centenary or afterwards. The completeness thus given to the volume is a further reason for regretting that, while its production is worthy of such a notable event, the volume has not been produced in a style which would place it within the reach of a much wider range of chemists and general readers to whom its present price may be prohibitive.

R. BRIGHTMAN

THE THEORY OF NATURAL SELECTION TO-DAY*

By PROF. J. B. S. HALDANE, F.R.S.
Indian Statistical Institute, Calcutta

WE constantly hear that Linnæus is out-of-date, that his ideas are a danger to clear thinking, and so on. Why, then, do we not relegate them to a place in the history of science, like those of his contemporary Scheele on phlogiston ? The answer is quite clear. Whatever we may think of Linnæus's theories, we continue to use his methods. In science, methods are much more important than theories, because a theory is an attempt to describe reality in terms of symbols made by the human vocal apparatus or on paper. If we think that the properties even of an electron are inexhaustible, theories can never be adequate. But a method, that is to say, a way of dealing with reality, may be adequate for the purpose for which it was designed, even if it is based on a false theory. The transition from a fluid to a particle theory of electric conduction in metals, and the partial return to a degenerate gas theory, had no effect on the design of galvanometers.

Linnæus invented the method of describing every animal or plant in terms of two, and only two, words. A group sharing the same two names is called a species. A group sharing the first only is called a genus. Genera are grouped together in higher categories, such as families, orders, classes and, more recently, phyla.

It is worth comparing this with some other methods of classification. To identify a particular star we give its right ascension and declination. In order to group stars which are judged to be similar, we use another two-dimensional classification. One co-ordinate is the surface temperature or a character highly correlated with it, such as the spectral type or colour. The other is the absolute luminosity. We then find that stars which agree in both these respects usually agree in others, for example, their period if they pulsate, their probable age, and so on. Linnæus tried such a two-dimensional classification of flowering plants, and it was one of his least-valuable contributions to biology.

The Linnæan system of classification is much more valuable in the tropics than in temperate or arctic climes, for the simple reason that there are many more different species of animals and plants. Linnæus's flora of Lapland was probably fairly complete. I am sure that nobody supposes that we have yet a complete list even of the flowering plants, let alone the ferns, mosses and liverworts, of Malaya. So it is no reproach to tropical biologists that they are still at the Linnæan stage when those of temperate climates have gone beyond Linnæus. One might as well reproach students of proteins because they cannot yet describe the structure of proteins with the accuracy possible for sodium chloride. It is therefore entirely fitting that we should be commemorating Linnæus on the equator.

If Linnæus's method of assigning every living organism to a species is so useful, why do we attack his species concept ? The species concept, like the concept of a molecule, is not always true ; but even where not true, both can be useful. Sodium chloride does not exist as molecules either in crystals or in solution. But it is convenient to use the same terminology to describe sodium chloride and carbon tetrachloride, though the latter is a true molecule. Similarly, we can describe a silicate the anion of which is a lattice of indefinite extent in terms appropriate to a small molecule. By the end of this century I expect that our chemical vocabulary will be brought up to date. I do not think the Linnæan terminology will be abandoned for several centuries.

The Linnæan species concept often breaks down when we extend our studies over a large enough space. Classical cases are the circum-Tibetan distribution of *Parus* and the circumpolar distribution of *Larus*. Here differences, which are at best subspecific, add up to a specific difference. The principal postulate of evolutionary theory is that all, or almost all, specific differences disappear if we trace the ancestry of two species far enough back. Thus, the horse and ass are believed to be descended from one ancestral species in the Pliocene, the horse and any bird from a common ancestral species in the Carboniferous. Finally, recent work on the transfer of substances (perhaps always deoxyribonucleic acid) responsible for hereditary differences, between bacteria not only of the same but also of different species, suggests that the species concept is only roughly applicable to bacteria.

But most biologists, and particularly experimental biologists, are dealing with organisms living in the present and obtained in a particular locality. The determination of their Linnæan species is a prerequisite to description of other observations. It may be said that the Linnæan system is merely a convenience of human communication. This is perhaps true, but it raises the question whether any scientific theory, or for that matter any philosophical theory, is anything more than such a convenience.

It is not a trivial fact that Linnæus worked on the periphery of the area where science was studied in his time. This meant that rather few of the plants and animals of his native country had been described either by the scientists of the ancient Mediterranean culture such as Aristotle and Theophrastus, or by such men as Aldrovandus and Gessner. Two centuries earlier, when Britain was similarly peripheral, Turner had realized that the plants and animals of his country required special study and special names.

It is not trivial that Darwin and Wallace were stimulated to formulate the theory of evolution as they did by observing the plants and animals of countries very distant from their own. A four-year voyage around the world gave Darwin enough facts inexplicable without a theory of evolution to last him a life-time, but in his case the theory germinated slowly. Wallace had spent much longer in the tropics, and produced a theory equivalent to Darwin's in a shorter time. It is not impossible that some resident in a scientifically peripheral area such as Singapore or Calcutta may to-day be making observations which will form the basis of an advance in biology comparable to those made by Linnæus two centuries ago, and by Darwin and Wallace a hundred years since. I shall later suggest reason to hope that Calcutta may be the locus of such a discovery.

---

* Substance of the presidential address delivered at the Centenary and Bicentenary Congress, University of Malaya, Singapore, on December 2, 1958. (See also p. 723.)

Darwin and Wallace not only championed the notion of evolution, but also produced a coherent theory as to how it had occurred. To-day almost all biologists believe in evolution, that is to say, they believe that the plants and animals alive to-day, including men, are descended from ancestors very unlike themselves, and that many very different living forms are descended from one ancestral species. However, by no means all living biologists believe that the main agency of evolution has been natural selection. Indeed, Wallace in his old age concluded that a decisive step in the evolution of man could not be so explained.

Darwin thought that evolution occurred by imperceptibly small steps. To-day we know that some of the steps have been fairly abrupt; and this is the main modification to which the account of evolution given a century ago must be subjected. These steps are of three main kinds. Mendel showed that on crossing races of peas certain characters showed no blending. Even when a character disappeared in the first generation it might reappear in a fraction of the next. We know that some evolutionary steps are due to the selection of characters inherited according to Mendel's law. About seventy species of British Lepidoptera have evolved black varieties since the industrial revolution, and some have almost completely replaced the original light form in the smokiest areas. In the best-studied case, *Biston betularia*, the dark form differs from the light by a single dominant gene. I shall later describe why the population evolved as it did. At present I merely wish to point out that the evolutionary process was not gradual, in the sense that the population did not pass through a phase of intermediate colour.

Secondly, the chromosomes, on which the genes responsible for Mendelian inheritance are carried, change abruptly. The number in a species is usually constant, and must be an integer, usually an even one. Not only does the number change, but also when a new species evolves, parts of two different chromosomes can be exchanged, so that in the hybrid the normal process of gamete production by meiosis is disturbed. This is not the only cause of hybrid sterility, perhaps not the main one, but it is one cause of this important biological fact.

Thirdly, and most important, we now know that a new species can arise in one step by the formation of a sterile or nearly sterile hybrid followed by a doubling of the chromosomes which renders it fertile but still vigorous. Such hybrids, which are called allopolyploids, breed very nearly true. While Winge and others must take much credit for this discovery, the most decisive steps were probably taken by the Japanese botanist Kihara, who recently crowned his life's work by discovering growing as a weed in wheat fields in Afghanistan the grass which, by crossing with a wheat like the macaroni wheats of to-day, gave rise to the bread wheats in or near Afghanistan about 6,000 years ago. It is probable that Kihara has made the most important amendment to Darwin and Wallace's account of evolution as a historical fact.

Finally, Garstang, Bolk, de Beer, and others have pointed out an evolutionary process at which Darwin and his immediate successors had not guessed. Many animals pass through a larval stage, and this may be highly specialized for its own kind of life. You have only to think of such familiar larvæ as a caterpillar and a tadpole. If the timing of development is shifted so that reproduction occurs when some or most of the non-reproductive organs are still in the larval stage, this may lead to the evolution of a wholly new adult type. Such are, for example, the Larvacea, or swimming tunicates, which resemble the larvæ of the sessile forms, but never attach themselves to rocks. It is probable that the Copepod Crustacea, a very successful order, are essentially larvæ of prawns or crabs which never grow up. A similar process has played a great part in human evolution. The development of our nearest relatives is very slow. A chimpanzee is not mature until about eight years. A human being is not mature until about sixteen, and never develops many of the characters of adult apes, let alone adults of other mammalian groups. In particular, we have kept the embryonic character of cranial flexure, so that our eyes are directed forwards and not upwards or even backwards. A change in the timing of sexual maturity may occur quite suddenly, as it does in the axolotl, and have very great evolutionary effects.

Nevertheless, palæontological research has, on the whole, fully confirmed Darwin and Wallace. Among the more spectacular 'missing links' which must have lived if their account of evolution is substantially correct, and are no longer missing, though they were so in Darwin's time, are amphibians with four legs but a fish-like tail with bone-supported fins, birds with long tails, teeth, and many other primitive features, and later short-tailed but still toothed birds. Our picture of vertebrate evolution is now so complete that one can make a list of dozens of discoveries, any one of which would go far to disprove the theory of evolution. For example, if the skeleton of a man or a horse were discovered in the Cretaceous, or that of a reptile or a bird in the Devonian, I, for one, would regard most of my life's work as having been as futile as that of an astrologer. Every year in which such discoveries are not made strengthens the evidence for the theory of evolution, and makes it less possible for biologists to accept any other theory.

Although both Darwin and Wallace made major contributions to the study of variation (and Darwin did some very important genetical work), we now know so much more than they did on these matters that their account of how evolution occurs must be restated. In my opinion, most of what they wrote is true; but the fact that they reached the truth on the meagre evidence before them is a proof of their genius.

Let me try to state the theory of natural selection as I hold it in language which they would have understood. "All species vary. But not all variation is inherited. Natural selection discourages most variations from the structures and functions normal in a species. It encourages a few variations; and if these are inherited, evolution will take place."

The main objection to this formulation is to the word 'inherit', which is applied to property and to characters. For example, I have inherited my father's watch, his baldness, and a growth of bristles on the nose. We could not both possess the watch simultaneously, but we were simultaneously bald. It may be incorrect to speak of possessing baldness, but we certainly possessed the nasal bristles simultaneously. A character is not an object like a watch, and it is misleading to use the same word about it.

The physical basis of heredity is now fairly well understood. Certain patterns in cells are copied with great fidelity when a cell divides. The most important are the molecular patterns which we call genes, and which determine what kinds of proteins will be built in the new cells, and thus may have a great effect on the structure and function of descendant cells and organisms. However, a character, such as tallness, hairiness, or capacity for distinguishing between green and grey, can only be said to be inherited if it depends in a fairly simple way, either on genes in the nucleus, or on the rarer copiable molecular patterns outside the nucleus. A change in one of these copied patterns, whether it is due to copying error or alteration between copyings, is called mutation.

Heredity can be defined statistically as a positive correlation between characters in a group of ancestors and their descendants, which is not due to a positive correlation between the environments of ancestors and descendants. My skin colour is hereditary in the biological sense, my linguistic habits are not. My mother taught me to speak English; but if I had been handed over to a Malay foster-mother as an infant, I could just as easily have learned to speak Malay.

An example of a biological and genetically determined character which is not inherited is the complete sterility of some so-called double-flowered plants such as the double *Matthiola incana*. Other characters, such as size within a pure line, are not inherited, because they are not genetically determined any more than are human languages.

Natural selection may be defined as a statistical difference between the parents of the next generation and the population from which they are drawn, each parent being counted once for each of its progeny. Darwin and Wallace thought mainly in terms of selection by survival, but fully recognized selection by fertility, parental care, and other means. We now see that selection, whether natural or artificial, is not always effective. For example, roan cattle (which, by the way, are common in England and very rare in India, though they exist, but may be unknown in Singapore) do not breed true, and selection in favour of roan may increase the frequency of roan to about 50 per cent, but cannot raise it above this level.

But as soon as biologists began to study natural selection they found something much more surprising. Natural selection is generally centripetal, that is to say, it favours individuals near the norm of the population in question, at the expense of those which deviate from it. In other words, the parents of the next generation are usually less variable than the generation of which they form a part. This is difficult to prove formally, because one cannot often determine parenthood in animals or plants under natural conditions, but it has been abundantly proved for many episodes of selection by killing. Perhaps the first case was Bumpus's observation in the late nineteenth century that of a number of sparrows picked up immobile with cold after a blizzard, those which did not recover were more variable in several measurable characters, such as wing-span, than those which did.

In the human species, centripetal selection occurs at all stages. For example, babies which are lighter or heavier than the average have a higher death-rate than the average. So have adults with very high or low weight or systolic pressure. When it comes to intelligence, the very stupid, who are classed as mental defectives, have a much higher death-rate than the average, and the survivors are less fertile than others, as they are largely confined in special institutions or in prisons. The very intelligent are probably longer-lived than the average, but are less fertile.

Centripetal selection acts partly by eliminating mutant genes, and partly by eliminating homozygotes, that is to say, organisms which have a like pair of genes, instead of an unlike pair, in a particular region of a chromosome. Thus, the first observations certainly confirmed Darwin and Wallace that natural selection occurs, but showed, contrary to their belief, that its main effect was to prevent species from changing. Only much later was natural selection with an evolutionary effect discovered.

The reason for this is clear enough. Evolution is a very slow process, how slow only Darwin guessed. He estimated the age of the Wealden, or upper Jurassic, at about 300 million years. His contemporaries, if they believed the theologians, put it at 6,000 years; if they believed the physicists, at about a million. The correct figure is about 130 million. In a fairly steadily evolving line such as the ancestors of horses, the average rate of change of a character, such as length of tooth, is about 4 per cent per million years. In 1924 I calculated the intensity of selection needed to make such changes. An advantage of one-thousandth for one type over another would be much more than enough; and this could only be detected on a sample of several millions, whereas a 10 per cent advantage could be detected on a sample of a few hundred.

In fact, natural selection with evolutionary consequences has only been observed where men have created drastically new conditions which impose a heavy selection pressure. The most striking is the use of insecticides such as DDT. This causes intense selection in favour of resistance to it, and relatively resistant races of mosquitoes arise in a few years. The best-studied case is that of the moth *Biston betularia*. In the smoke-polluted parts of Britain the original light form is conspicuous when resting on tree trunks, as these moths do during the day. In the unpolluted areas the dark form is equally conspicuous. Kettlewell found that birds ate the form which is conspicuous to human eyes at such a rate that if equal numbers of the two forms are released at dawn, the ratio of inconspicuous to conspicuous moths caught in flight the next night is 2 : 1. Thirty years earlier I had calculated, from the rate at which the numbers of the black form had increased, that the fitness of the light form in smoke-polluted areas was about 70 per cent of that of the black. This may well be true on an average, for Kettlewell chose a highly blackened wood near Birmingham for his experiment.

I have no doubt that natural selection of much less intensity, but yet with an intensity far greater than that which has been usual in the past, is going on in many species. But it would be difficult for a single worker to collect the data.

Can natural selection explain evolution? If Darwin thought that it could, this was perhaps because he thought that members of a species varied in all possible directions, and natural selection could favour any kind of variation. This is probably not so. Only certain kinds of heritable variations seem to be possible in any particular species. The course of evolution is not (except perhaps in very rare cases) determined by the frequency with which a particular type of mutation occurs; and the vast majority of mutations are rejected as useless, the process of rejection being called centripetal selection. No important event has only one cause. Houses would not be burned down if they were all made of ferroconcrete, or if the air only contained 17 per cent of oxygen. If there were no mutation, natural selection would be ineffective; if there were no natural selection, every species would become a collection of freaks. Only in this rather restricted sense can it be claimed that natural selection explains evolution.

However, it does not follow that the claim is true. In contradistinction to Wallace, I think it probably is true. Let us take such an organ as the eye of a man or a bird. It has been argued that it could not have evolved by natural selection, because it would seem that any improvement, in the later stages at least, would require simultaneous changes in several of its measurable magnitudes. I think a careful study of the eyes of living molluscs greatly weakens this argument, as we can find among them a dozen or so stages from a mere light-sensitive spot to an eye with a lens and retina much like our own. Wright has shown how, in small animal or plant communities, several changes, each slightly harmful, but beneficial in combination, may occur together.

Wallace regarded the origin of certain characters which he considered to be specifically human as inexplicable by natural selection. Many such characters, including a disposition to monogamy and a respect for property, both of which human moralists might envy, have since been found in animals. I have also shown, or at least suggested, how a mode of behaviour originated by the initiative of a single individual, and then converted, by imitation, into a tradition, may become instinctive as the result of natural selection. Until it has been shown that my arguments are worthless, it may be rash to say that natural selection cannot account for such changes. It is equally rash to assert dogmatically that it can.

If this celebration were merely concerned with eulogies of three great men, it would be worse than useless. If it helps us to imitate them, it is of the greatest value. Linnæus, Darwin and Wallace had this in common, that they did not use complicated apparatus. Any student to-day would turn up his nose at Darwin's microscope. Now we in India find it difficult to get apparatus. This discourages us from some lines of biological research. We cannot get electron microscopes, highly purified amino-acids, and so forth. But we can get land and labour to grow plants or keep animals, we can collect them on a large scale, and we can at least travel all over India. I want to tell you what I am trying to do in these circumstances.

I have already acted as a catalyst in getting one of the world's leading palæontologists (Dr. Pamela L. Robinson, University College, London) over here; and, with Indian colleagues, she has, in about ten weeks work, obtained reptilian and fish fossils, some of which are new to science, while others date some mesozoic formations with considerable precision (*Nature*, 182, 1722; 1958). Similarly, I hope shortly to catalyse the visit of one of the world's leading systematists to attack a group of animals the Indian representatives of which are practically unknown. My own junior colleagues are at last continuing the study of variation where Karl Pearson and Bateson left it fifty years ago.

Perhaps I may begin with a discovery made by a colleague, Mr. K. Dronamraju. Darwin directed attention to heterostylism in *Primula* and other genera. In many species there are two types of plant, in one of which the flowers have long styles, in the other short. The position of the anthers also differs. The phenomenon is called heterostylism. Darwin found that crosses between flowers of the different types gave far more seed than the so-called illegitimate unions between plants of the same morphological type. As no work of this kind has been done in the tropics, I asked Mr. Dronamraju to look for a suitable plant near the Indian Statistical Institute; for the assessments of fertility and of the viabilities of seeds in such cases raise some interesting statistical problems. Mr. Dronamraju discovered something much more important. He found both long-styled and short-styled flowers growing together on each of five trees of *Bauhinia acuminata*. So far, his results are merely statistical. In a year or two I hope that he will have physiological results also. This observation would most certainly have excited Darwin, who did not attempt to hide his emotions, so that his books are full of such adjectives as 'wonderful' and 'beautiful'. It is at least possible that heterostylism started as a variation between flowers on the same plant, and that, later, genes which controlled it were evolved.

Another colleague, Mr. S. K. Roy, is also almost slavishly imitating Darwin's interests. He has measured the amount of earth brought up by earthworms in Bengal and Bihar, and his measurements are the first to be made in Asia. A proper understanding of Asian soils demands that they be repeated in a thousand different places. I hope that some will be in Singapore or Malaya. He is now working, among other things, on variation in the like parts of the same plant. In a number of individuals of three different species he has reached the startling conclusions that while the mean number of petals per flower does not alter much during a season, the variance usually increases, and may be doubled. If the size of pots made by a potter became more variable at the end of a day, we should say that he was getting tired. I do not know what we are to say about a plant. To reach this conclusion, Mr. Roy has examined about 200,000 flowers. It is an interesting coincidence that Dr. A. K. Sharma, with his wife and other colleagues in the University of Calcutta, are working on differences in chromosome number in different organs of the same plant.

The point which I want to make is this. Apart from genetics, which can scarcely be understood without some special knowledge, no work is going on under my supervision which Darwin or Wallace would not have readily understood, and which is not, in fact, a continuation of a line of work started by one of them. Nevertheless, most of it is original in the sense that it is not an attempt to extend to tropical animals and plants principles which have already been established as holding in Europe, North America or Japan. It was Wallace, above all, who saw that certain biological problems are forced on one by a study of tropical life, which are by no means so obvious in temperate climates. The converse is, of course, true. Many ecological questions are fairly simple in the arctic regions, where a biotic community may consist of only twenty or thirty species; more difficult in the temperate zone, where a hundred or more species must be considered; and extremely complicated in a tropical rain forest, where it might be necessary to consider thousands of species, many as yet undescribed.

RIVER FLOW IN GREAT BRITAIN, 1955–56

By PROF. DAVID L. LINTON
Department of Geography, University of Birmingham

HYDROMETRIC statistics derived from regular measurements made at gauging stations on British rivers were first published by the Ministry of Health in 1938 and then lapsed during the War. Two volumes, published in 1952 and 1955, each covering eight years, brought the record (in a condensed form) up to 1953. "The Surface Water Year Book of Great Britain, 1955–56" (H.M.S.O. For the Ministry of Housing and Local Government, 1958. 15*s*. net) is the third in the new series. [It has been followed after a short interval by the fourth of the series, dealing with the period 1956–57.] The volume for 1955–56 contains results derived from 128 gauging stations maintained for a variety of purposes by river boards, water-supply undertakings, county councils, hydro-electric authorities, and others, and gathered together by the Surface Water Survey. For a minority of stations the records are incomplete or defective in some respect; but for the great majority we are given for each month of the hydrological year (October 1955–September 1956) the observed mean rate of discharge in cusecs (cu. ft./sec.): the gross mean (or natural) rate of discharge (in which allowance is made for additions or abstractions for reservoir, canal or hydro-electric purposes); the highest and lowest mean daily rates of discharge in cusecs, and the highest observed rate of discharge in cusecs however brief its duration, together with the date of its occurrence. From these data two further quantities are derived and tabulated for each month, namely, the gross mean discharge per square mile of catchment area, and the 'run-off', while the rainfall received in each of the twelve months and the corresponding mean monthly rainfalls are added for comparison. Finally, appropriate yearly rates or totals are quoted and some data are supplied concerning the location and character of the gauging station, the extent and hydrological character of the area draining to it, and the length and nature of the record.

Examination of the tabulated figures does not need to be very prolonged to reveal that the Tay is the most copious river of Great Britain. Its mean rate of discharge of 4,146 cusecs for the water year 1955–56 (and of about 4,000 cusecs over a ten-year period) at Caputh, where it emerges from the Grampian Highlands after draining 1,238 square miles, is not even approached by any rival. The Ness outflow of Loch Ness yielded 2,574 cusecs, and the Spey at Aberlour 2,188 cusecs from 692 and 1,020 square miles, respectively, and these figures differ little from longer-period averages. The figures for the 1955–56 mean flows of the Thames at Teddington (3,810 square miles), the Severn at Bewdley (1,650 square miles) and the Wye at Cadora (1,560 square miles) were 1,811, 1,557 and 1,806 cusecs, but longer-period averages of 2,373, 2,285 and 2,484 cusecs, respectively, are quoted. Maximum flows for a single day follow a similar order: in 1955–56 they were for the Tay 31,500, Ness 12,000, Spey 20,000, Thames 10,700, Severn 13,200 and Wye 13,900. Over longer periods higher rates of flow have been recorded or estimated, namely, Tay 42,000; Ness 20,900; Spey 27,000; Thames 27,900; Severn 23,000 and Wye 32,000. Some other rivers have had high flood flows, and the figures of 40,000 cusecs for the Aberdeenshire Dee at Woodend from 220 square miles; of 16,800 cusecs for the Welsh Dee at Erbistock from 401 square miles; and 21,000 cusecs for the Irwell in Manchester from only 226 square miles, are notable.

The Tay is the only British river for which the mean daily flow never fell to 1,000 cusecs during 1955–56. Minimum daily flows for the other rivers mentioned above were Ness 550, Spey 585, Thames 243, Severn 320 and Wye 312. Minimum flows for purely lowland rivers may fall to such very low values as 23 cusecs for the Great Ouse at Bedford or 21 cusecs for the Nene near Peterborough, because of high summer evaporation. For such rivers the ratio of the largest and smallest mean daily flows may be 80 or 90 to 1. For the Ness, on the other hand, it is less than 22, while for the Tay, Thames, Severn and Wye the ratios are 30, 44, 41 and 45 to 1. Very high values of this ratio are found for many small streams, of which 180 for the Monnow, 237 for the Medlom and 900 for the Essex Blackwater may be cited as examples.

Since rates of flow are tabulated for each month of the water year, seasonal variations can to a certain extent be studied. Highest values are most generally in December, January and February, when evaporation and transpiration are at a minimum. Other high values may reflect either seasonal rainfall maxima in October and August normal to the areas concerned, or high discharges connected with particular rainy spells. Comparison of the flow records with the periods of heaviest rainfall tabulated in the pages of "British Rainfall" would doubtless be revealing. Since seasonal flow can be so dominated by spells of abnormally heavy rain, many years records will be required before normals of monthly flow can be established.

While the points mentioned above are evidently of interest, they do not lend themselves to any but the crudest comparisons of one stream with another. For more refined or more far-reaching analysis, cartographic treatment is necessary, and it is remarkable that nothing of the kind is attempted in the present volume. Four quantities which will here be called the 'run-off', the 'run-off deficit', the 'specific discharge' and the 'discharge ratio', are appropriate for such treatment. Of these, the first is tabulated for 107 gauging stations, and the third (though under another name) for 109; the other two have not apparently received any consideration by the Surface Water Survey; but they can readily be derived for the 90 catchment areas for which the total rainfall for the hydrological year 1955–56 has been supplied. The cartographic representation of these four quantities is shown in Figs. 1, 2, 3 and 4.

In the catchment basin of any stream above a selected gauging point, the rainfall received in a water year will, of course, vary from point to point, possibly quite widely; but if enough records are available an isohyetal map may be drawn and the mean rainfall (P) may be determined and expressed in inches. A sheet of water of that depth and covering

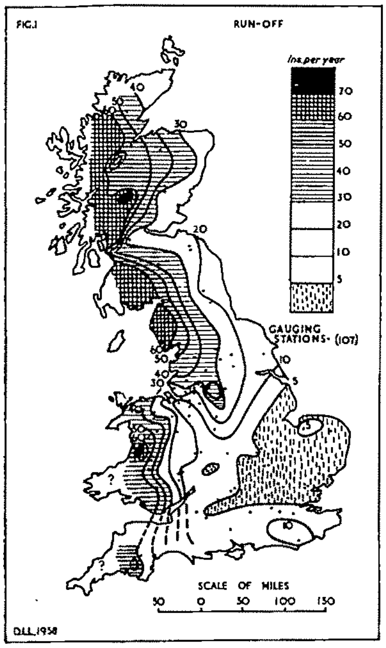

FIG.1 RUN-OFF

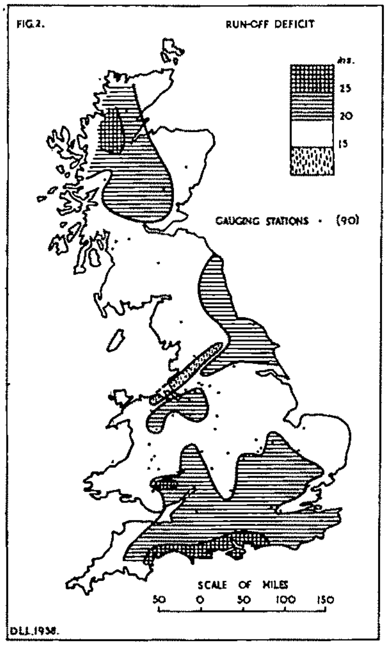

FIG.2. RUN-OFF DEFICIT

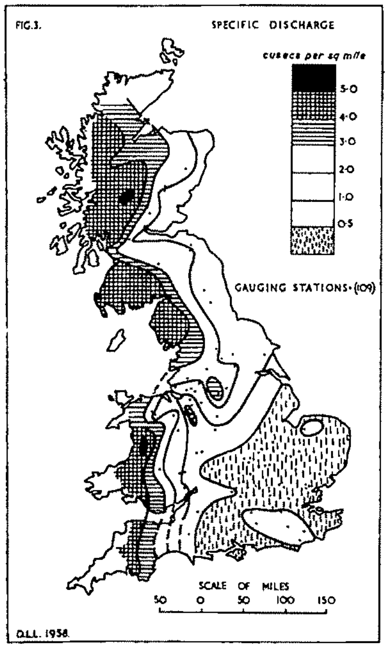

FIG.3. SPECIFIC DISCHARGE

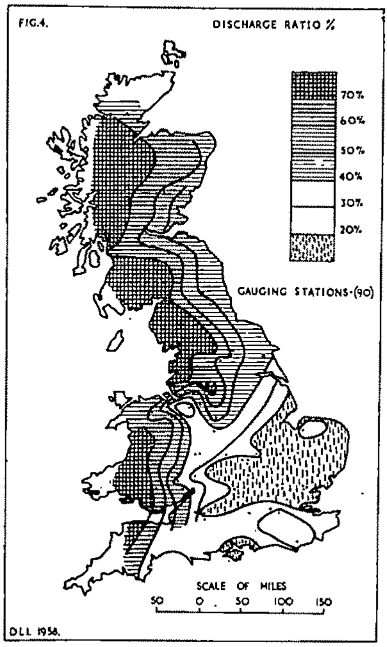

FIG.4. DISCHARGE RATIO %

the area of the drainage basin would equal in volume the total rainfall received. Of this total, a quantity (Q cu. ft.) is actually delivered to the gauging station in the course of the year. This quantity deserves a name, and, it is here suggested, may best be called the annual 'delivery' of the basin. If the delivery (Q cu. ft.) be divided by the area (A sq. ft.) of the basin, the quotient is a quantity exactly comparable to the mean rainfall of the basin, and like it may be expressed in inches. This is tabulated for 107 streams as the 'run-off' (R), and its variation over a large part of Great Britain is shown in Fig. 1. It is thought that the features shown by this map for 1955–56 would strongly resemble those for any other water year, and that they are, therefore, worth a little discussion. The wide range of variation (the ratio maximum/minimum is 73/1·7 or 43) will at once be noted as greatly exceeding the range of mean rainfall (200/19 = 10·5) in the same area. Moreover, it will be noted that extreme high and low values prevail over larger areas than the extremes of rainfall. Almost the whole of the English Plain, which receives rainfalls of 20–35 in., has run-off values less than 10 in. a year, and over most of East Anglia, the Fens and the Thames Valley the values are less than 5. At the other extreme, large areas in western Scotland and Cumbria, and small areas in Wales and Dartmoor, yield an annual run-off in excess of 60 in., though no data are available concerning the run-off in western coastal districts. Between the extremes, values of R fall off sharply from west to east and the isopleths probably migrate eastward in wet years and westward in dry years, leading to marked year-to-year fluctuations in areas like Peebles, the West Riding, or Herefordshire. An interesting feature is the extension of quite low run-off values as far as Chester in the rain-shadow of the Welsh uplands, and the rapid increase northward through Lancashire to Morecambe Bay. The local increases shown in Norfolk, the Sussex Weald and the High Peak are probably real features, though they may well be less marked in other years. On the other hand, the local minimum recorded for a small stream (Allt Bhlaraidh) west of Loch Ness appears out of accord with other available records in the region (Beauly, Ness and Lochy) and it is possible that it may be untrustworthy.

It is evident that the run-off (R) may be expected to be less than precipitation (P) in the same area by an amount representing the water lost by evaporation from the ground or transpiration from natural vegetation or crops. The amount of this difference ($P - R$) is thus a measure of evapo-transpiration and may be termed the 'run-off deficit' (D). Values of D in inches are expressed cartographically in Fig. 2. Here the range of variation in the recorded values is quite small (28·2/12·3 = 2·3 only) and, in fact, most of the values depart only by small amounts from 20 in. a year. There is a detectable tendency for higher values to occur in the south, where evaporation can be expected to be greatest, but high values are also recorded in the Scottish Highlands, presumably reflecting the great amount of exposed water available for evaporation. Elsewhere the variations appear a little capricious, and doubtless reflect in some way the influence of particular weather spells in certain areas. This map will probably show much variation from year to year in the location of the isopleths; but the broad fact that it reveals—namely, that evapo-transpiration levies a sort of overhead charge of roughly 20 in. a year from each and all the river basins of Britain—is doubtless a long-term reality. Figs. 1 and 2 are, in fact, complementary. Together they account for the whole of the rainfall received in the water year ($R + D = P$), but they show that the geographical variation of the fractions disposed of by run-off and by evapo-transpiration is radically different. It is to be doubted whether there has previously been any general appreciation of this difference by water engineers or others.

The third map (Fig. 3) shows variations tabulated in the report as "gross mean discharge per square mile", that is, the mean quantity of water in cubic feet contributed every second from every square mile of the catchment basin concerned to its total delivery. Since it represents the flow contributed per unit area it would seem appropriate that this quantity should be called the 'specific discharge' (S). Physically it has the same dimensions as the run-off, the two quantities being numerically related thus:

$$\frac{R}{12} = S \times \frac{365 \times 24 \times 60 \times 60}{5280 \times 5280} \text{ or } \frac{R}{S} = 13{\cdot}57$$

Ideally, therefore, the 2-in. isopleth in Fig. 3 should correspond to an isopleth of 27·15 in. of run-off in Fig. 1; but because the nearest isopleths in Fig. 1 are drawn at 20 and 30 in. some divergences, of course, actually appear. The map of specific discharge yields no distributional information not implicit in Fig. 1 but gives numerical expression to a very different way of regarding the same data. Whereas Fig. 1 obviously invites comparison with the rainfall map, Fig. 3 allows one to say simply by inspection that the mean flow in 1955–56 from 120 square miles of catchment in Caermarthenshire probably exceeded 480 cusecs, while the flow from an equivalent area of east Suffolk was probably less than 60 cusecs, though there were no gauging stations operating in either area during the year.

All three quantities so far discussed may show considerable variations from one year to another at a given locality. The quantity mapped in Fig. 4, however, is more likely to be conservative and to reveal essential and persistent differences between one part of Britain and another. This quantity has for twenty years or more been discussed by French geographers under the name *coefficient d'écoulement*, for which it is suggested that an appropriate English term would be 'discharge ratio'. It is simply the ratio R/P expressed as a percentage. When mapped it shows a wide variation (75/12·7 = 5·9) which expresses the combined effects of two fundamental geographical contrasts—that between upland and lowland, and that between the windward and leeward sides of the country. This is really the basic map of the hydrological characteristics of the country, and it is to be hoped that in future gauging stations will be established on the streams of Caithness, the west of Scotland, north-west and south-west Wales, Cornwall, Dorset, East Anglia, Lincolnshire and the north-east of England, to permit the blank areas of the map to be filled in.

When this has been done and mean values of the discharge ratio have been established for the whole of Britain over a period of years, we shall be possessed of a map which will reveal the very different endowment of the different parts of the country in respect of one of its basic resources—available surface water. Prof. W. G. V. Balchin has more than once in recent years stressed that over much of England the increasing demands for domestic and industrial water cannot long continue to be met locally, and has called for a stocktaking of our water resources as a first step to overall planning of water distribution and use[1]. It is urged here that maps of the kind now offered for the first time for Great Britain are basic documents for understanding our water situation and for planning for the future. It is very much to be hoped that the Surface Water Survey will itself, in future annual reports, undertake the presentation of its data year by year in this form, and in due time will undertake the preparation of maps of long-period monthly and annual means.

THE McGILL–MONTREAL GENERAL HOSPITAL RESEARCH INSTITUTE

By Prof. J. H. QUASTEL, F.R.S.

THE McGill–Montreal General Hospital Research Institute, which has just celebrated the tenth anniversary of its foundation, is housed in an old three-story residence located on University Street, which is in the heart of Montreal, close by the McGill University buildings. It is situated very near the McGill Medical School, the Royal Victoria Hospital and the Montreal Neurological Institute.

The Institute arose as a result of a decision made in 1947 of the Board of Management of the Montreal General Hospital, upon the recommendation of its Medical Board, that the establishment of a laboratory devoted to the solution of medical problems by fundamental biochemical methods would be an important step for the development of medicine in Canada. The primary movers for the establishment of such an Institute were Dr. I. M. Rabinowitch, Dr. C. C. Birchard, Dr. B. S. Johnston and others, all members of the Medical Board of the Montreal General Hospital, who were convinced that medical progress to-day is greatly dependent on biochemical advances and achievements. When the Institute was inaugurated in 1948 it was the first of its kind to be established in a Canadian hospital.

Almost eight years after its inception, when the initial staff of five had grown to thirty, the Institute was incorporated into McGill University. The premises, which had been acquired by the Hospital from the University with funds given by Mr. T. H. P. Molson and the late H. W. Molson, reverted to McGill ownership. A special committee appointed by the Hospital considered that the scope of the Institute's activities would be broadened through a closer association with related McGill departments and McGill teaching hospitals. The incorporation was a natural consequence of the Institute's fundamental research work, which remains, however, intimately connected with practical medical problems.

The present somewhat ponderous name of the Institute recognizes a double loyalty, to the Hospital which brought the Institute into being, and with which a close association is maintained, and to McGill University, which embraces the Institute as part of its family of research units. As a member of the McGill Research 'family' the Institute has become a valuable training ground for students and for postgraduate investigators. The present writer is director of the Institute and professor of biochemistry in McGill University; two members of the staff of the Institute, Dr. P. G. Scholefield and Dr. E. H. Creaser, are assistant professors of biochemistry in the University.

The Institute has, at present, a staff of thirty-five, of whom sixteen are students working in the field of biochemistry for their Ph.D. degrees under the supervision of senior members of the Institute, and twelve are post-doctoral investigators. Both the students and post-doctoral investigators are drawn from various parts of the world. At present, as many as twelve different nationalities are represented. There are members, for example, from Canada, Britain, Australia, India, Pakistan, Japan, the Philippines, Hungary, Greece and Poland.

More than 150 original scientific articles have been published, from the Institute, by members of the staff since the Institute was opened about ten years ago. They are all in the biochemical field, and are concerned with investigations mostly undertaken because of their relation to medical problems. Some of the work lies in the cancer field, some in a field of study devoted to problems of the central nervous system, some in the fields of virology and microbial chemistry, and some of the work is associated with the subject of intestinal absorption. The problems that have been, and are being, investigated are concerned with the biochemical behaviour of cancer cells and of embryonic cells, with the effects of anti-metabolites on cell processes, with the mode of action of narcotics, anæsthetics, alcohols, and other substances affecting the behaviour of the nervous system, with the metabolic problems concerned with virus growth, with the mode of action of antibiotics, with the role of amino-sugars in metabolism, etc. These investigations, pursued at a fundamental level, make it possible for students in the Institute to acquire a broad experience of biochemical problems and techniques. Much of the work is necessarily enzymological in character, and a good knowledge of the biochemistry of enzymes is indispensable for the approach taken, in the Institute, towards its various problems. Radioactive techniques and procedures are followed in almost every phase of the work. Problems of nucleic acid metabolism and nucleotide synthesis, protein synthesis, phospholipid synthesis, all problems which are being actively investigated in the Institute, require their due quotas of carbon-14, phosphorus-32 and sulphur-35. Geiger counters operate on each floor of the old residence, and precautions have to be taken that no contamination by radioactive materials makes its appearance in the laboratories. Tumour transplantation in animals is carried out fairly extensively, as may be expected in an Institute which has to do with cancer problems, but the fact that transplantation of certain tumours into embryonated eggs is a successful procedure relieves to some extent the pressure on the animal house and the high cost of animal upkeep.

The Institute, now an active biochemical research centre, is very crowded, and there is no part of the old residence, in which the Institute is housed, that is not put to good use. It is well equipped, and it is surprising how well the many rooms of various dimensions serve as laboratories. Much of the laboratory furniture is home-made, and there is an excellent workshop that is indispensable for repair work as well as for the building of instruments.

Almost the entire work of the Institute is financed by grants and fellowships from a variety of organizations such as the National Cancer Institute of Canada, the Cancer Research Society, Inc., the National Research Council of Canada, the Rockefeller Foundation, the National Science Foundation and other scientific societies without the financial support of which the Institute could not survive. A number of commercial firms have also generously assisted the Institute; to these the Institute is very greatly indebted. The fact that the research work of the Institute depends so greatly on the financial help of many organizations, who support its work after due examination and appraisal of submitted projects, makes the task of organizing long-term research programmes a difficult one. It is greatly hoped that the Institute will one day be given a permanent endowment that will make it possible for the Institute to carry on part of its work without financial anxiety.

The Institute has been fortunate in the co-operation afforded it by the various departments of McGill University and its teaching hospitals, and also in the warm friendliness and active help of the chairman of the Biochemistry Department, Prof. D. L. Thomson. As Dr. F. C. James, principal of McGill University, and Mr. W. W. Ogilvie, president of the Montreal General Hospital, have justly stated, in a foreword to a brochure recently issued concerning the Institute, McGill University has long pioneered in many important fields of research. Since the days of Rutherford and Osler, McGill investigators, and others connected with the University, have contributed greatly to scientific and medical knowledge. The Institute is doing its best to maintain this tradition. Its success so far is due largely to the enthusiasm, devotion and hard work of its members, and it looks forward to a very productive future.

OBITUARIES

Dr. G. M. Bennett, C.B., F.R.S.

George Macdonald Bennett was born on October 25, 1892. His father, the Rev. J. E. Bennett, a great admirer of George Macdonald, the Scottish writer, had entered the Baptist ministry but established a private boarding school, Clacton College, towards the end of the past century, putting into practice many ideas which were then unorthodox but are now more generally accepted. Here Bennett received his early education; after the founder's death, the school was continued by Harold Picton, one of Ramsay's brilliant young men who had become associated with it in 1900. It is a tribute to this school, and perhaps more to the young Bennett's remarkable talents, that when he left it for East London (now Queen Mary) College in 1909 he embarked on an honours course in chemistry which he pursued by day while continuing with a correspondence course for an arts degree in the evenings and at week-ends. The resulting B.A. (1911) and B.Sc. (first-class honours, 1912) by the age of twenty foreshadowed the brilliance of his career.

In 1913 Bennett won an exhibition at St. John's College, Cambridge where he read chemistry, physics and mineralogy, taking a first class in both parts of the Tripos and being elected a Fellow of the College in 1917. He was then working under Prof. W. J. Pope, but his active mind ranged beyond the immediate war-time work, such as that on ββ′-dichlorodiethyl sulphide, and turned to crystallography, which he had learned under Hutchinson, and stereoisomerism.

Soon after the end of the First World War, Bennett worked for a short time with Strange and Graham, a firm of consulting chemists, and then was appointed a demonstrator at Guy's Hospital, London. From here, in 1924, he went as lecturer to the University of Sheffield, where in 1931 he succeeded Prof. W. Palmer Wynne as Firth professor. After seven years he returned to London to fill the vacancy caused by the retirement of Prof. Samuel Smiles at King's College, London, and soon had to cope with evacuation to Bristol. Here, although his department suffered from bombing, Bennett kept the teaching going and maintained an output of research.

In 1945, on the death of Sir John Fox, Bennett was appointed Government chemist. To some, this seemed a strange transition, but those who knew his wide knowledge and his mastery of detail were sure that he would justify the appointment—as he did, for the normal tenure was extended, but he did not live to complete the additional two years.

Space permits only a brief mention of a few of the lines along which Bennett worked, but these are selected to show his wide interests: surface tension and the constitution of liquids; isomerism of some ferrocyanides; reactivity of the chlorine atom in chloro-substituted sulphides; velocities of reactions of various types, particularly with reference to polar effects; glycols and thioglycols; stereoisomerism of disulphides, dioxides and related substances; valency angle of oxygen and of sulphur; crystal form of anhydrous citric acid; configuration of heterocyclic compounds; formation of large-ring sulphur compounds; liquid crystals; mechanism of nitration.

Bennett received the degrees of Ph.D. of London and M.A. and Sc.D. of Cambridge. He was elected to the Royal Society in 1947 and was appointed a Companion of the Bath in 1948. He was among the first old students to be made a Fellow of Queen Mary College. He was an honorary secretary of the Chemical Society from 1939 until 1946, having served on the Council during 1929–32, and was vice-president from 1948 until 1951. He served the Royal Institute of Chemistry on the Council for two years, as examiner for five years, and as vice-president for two years.

In 1918 Bennett married Doris Laycock, a Cambridge graduate, and her tragic death at Christmas 1957 from a rapid form of cancer no doubt aggravated the heart trouble from which he died suddenly and peacefully on February 9, 1959. He combined great gifts with humility and kindliness.

A. D. Mitchell

Dr. H. D. K. Drew

Harry Dugald Keith Drew died in London at the end of December at the age of seventy-two. He was educated at Queen Elizabeth's School, Barnet, and at Birkbeck College, London, graduating B.Sc. in 1910. His active professional career as a chemist began in 1919 when he joined G. T. Morgan, then professor of chemistry in Birmingham, as research assistant, after war service in the R.N.A.S. In 1922 he was appointed to the teaching staff of the University of Birmingham as lecturer in chemistry; in 1930 he became reader in organic chemistry in the University of London at Queen Mary College, a post which he held until he retired in 1947.

Drew's earliest published work was in collaboration with G. Senter and with A. McKenzie, and was concerned with the investigations on the Walden inversion which were then being carried out at Birkbeck College. In his later work, the interest in stereochemistry was maintained and developed along independent lines. The most striking of these researches was a re-investigation of Vernon's observations on the isomerism of the dialkyl telluronium dihalides, which were assumed to be *cis-* and *trans*-isomers resulting from a planar distribution of the valencies of tellurium. Drew established that the difference between the red α-dimethyl telluronium diiodide and the green β-compound is not one of *cis–trans* isomerism; the green compound has a salt-like character, Me_3TeI, $MeTeI_3$, whereas the red α-compound is Me_2TeI_2. He also inferred a tetrahedral distribution of the tellurium valencies. There were other investigations on tellurium and selenium organo-metal compounds, notable among these being the study of the interaction of tellurium tetrachloride with β-diketones.

In a series of papers from 1930 onwards, some in collaboration with the late Prof. W. Wardlaw and his school, the structure of platinum co-ordination compounds was examined in some detail and many of the inconsistencies and earlier conclusions corrected. Other topics which attracted Drew's interest were chemiluminescence and the metal lakes formed from orthohydroxy azo-compounds. While he was still on the staff in Birmingham, Drew was drawn into work with W. N. Haworth on the investigation of the ring structures of the sugars, and in this both he and E. L. Hirst played an important part in this revision of the then accepted structures.

In the late 1920's, Drew spent a period in Pregl's laboratory in Graz, and he returned enthusiastically in favour of the new system of micro-analysis of carbon compounds. He set up a laboratory for teaching Pregl's methods, and gave regular courses of instruction both in Birmingham and in London to undergraduate and graduate students. He also set up what was probably the first laboratory for the routine microanalysis of carbon compounds.

Drew was a man of many gifts and interests, among them an active interest in tennis and cricket, yet he never conquered his shyness and reticence to become well known even to his colleagues. The over-riding interest in his life was the practice of chemistry, and to those who had the opportunity of seeing him work at the bench, his skill with small amounts of material and his ability to extract pure crystalline products from the most unpromising material seemed uncanny. He was a man who practised his craft essentially for the satisfaction of accomplishment and not for any personal gain or reward.

W. J. Hickinbottom

NEWS and VIEWS

Royal Society of Edinburgh : New Fellows

At the ordinary meeting of the Royal Society of Edinburgh, held on March 3, the following were elected Fellows of the Society : Dr. S. Alstead, regius professor of materia medica, University of Glasgow ; Dr. H. Barnes, principal scientific officer, Marine Biological Station, Millport ; Dr. D. Borwein, lecturer in mathematics, University of St. Andrews ; Dr. A. F. Brown, lecturer in natural philosophy, University of Edinburgh ; Prof. R. Brown, professor of botany, University of Edinburgh ; Dr. H. E. Butler, principal scientific officer, Royal Observatory, Edinburgh ; Prof. R. Cruickshank, professor of bacteriology, University of Edinburgh ; Prof. J. Drever, professor of psychology, University of Edinburgh ; Mr. W. D. D. Fenton, chairman, Uganda Electricity Board ; Prof. J. C. Gunn, Cargill professor of natural philosophy, University of Glasgow ; Prof. A. A. Harper, professor of physiology, King's College, Newcastle upon Tyne ; Prof. A. Macdonald, professor of bacteriology, University of Aberdeen ; Dr. W. S. Mackenzie, lecturer in geology, University of Manchester ; Prof. R. H. Matthew, professor of architecture, University of Edinburgh ; Dr. T. A. Munro, physician-superintendent, Royal Edinburgh Hospital for Mental and Nervous Disorders ; Dr. E. M. Patterson, lecturer in mathematics, University of Leeds ; Prof. W. L. M. Perry, professor of materia medica, University of Edinburgh ; Dr. D. L. Pursey, lecturer in mathematical physics, University of Edinburgh ; Dr. J. H. Sang, assistant director, Agricultural Research Council Poultry Research Centre, Edinburgh ; Dr. R. J. Scothorne, senior lecturer in anatomy, University of Glasgow ; Dr. M. A. H. Tincker, principal, North of Scotland College of Agriculture, Aberdeen ; Dr. D. Traill, research director of I.C.I., Ltd. (Nobel Division), and director of research ; Prof. A. D. Walsh, Baxter professor of chemistry, Queen's College, Dundee ; Dr. E. W. Walsh, senior lecturer in physiology, University of Edinburgh ; Mr. K. Williamson, migration research officer, British Trust for Ornithology, Oxford.

Chemical Engineering at Cambridge : Prof. T. R. C. Fox

Many will learn with surprise and dismay that Prof. T. R. C. Fox has decided to relinquish the Shell chair of chemical engineering in the University of Cambridge, due to ill-health. When the chair was established in 1946 the number of university departments in chemical engineering in Britain was woefully small and the electors for the professorship had some difficulty in finding the right man for a position that would unquestionably have a great influence on the teaching of chemical engineering in Britain. Prof. Fox had taken a keen interest in the work of this Department from the first mention of its setting up by the Shell Company, and with his background of four years in Imperial Chemical Industries, Ltd., at Billingham, followed by a period as a lecturer in mechanical engineering at Cambridge, Prof. Fox, at the early age of thirty-four, was an outstanding choice. He was already well established at Cambridge, having been an undergraduate at Jesus and a Fellow of King's, and the past twelve years have shown how well this choice has worked out. The Department has built up a reputation in chemical engineering throughout the Western world, and several chairs of chemical engineering in British universities are now occupied by men who have served with Prof. Fox at Cambridge. All those who know him will trust that his health will soon be fully restored.

Prof. P. V. Danckwerts, G.C., M.B.E.

Prof. P. V. Danckwerts was one of the first of those to take part in the building up of the Shell Department of Chemical Engineering at Cambridge, and it does not detract from the feeling of loss that Cambridge will experience in losing Prof. Fox to say that it is a very pleasant thought that the chair will be occupied by Prof. Danckwerts, who is forty-two. His scientific education was begun at Oxford, and after war service in the R.N.V.R., during which he was awarded the George Cross, he spent some time at the Massachusetts Institute of Technology. He returned from there in 1948, in order to take up a position at Cambridge in the new Department, and later joined the U.K. Atomic Energy Authority as deputy director of research and development in the Industrial Group. In 1956 he was invited to take up a professorship in the Department of Chemical Engineering at the Imperial College of Science and Technology, London. During his stay at the Imperial College he has been actively concerned with the re-organization of the syllabus for the teaching of chemical engineering in the University of London and he will bring much experience, both in modern industry and in the teaching of chemical engineering, to Cambridge.

Department of Anthropology, Government of India : N. K. Bose

Mr. Nirmal Kumar Bose, reader in anthropogeography in the University of Calcutta, has been appointed director of the Anthropological Department, Government of India. He took his B.Sc. in geology and his M.Sc. in anthropology in the University of Calcutta. He is well known for his work on the dating of Indian architecture, where documentary evidence is seldom available, and there has been an unfortunate tendency to base dates on a highly hypothetical history of Indian æsthetics. He has done much to introduce more objective methods. He has discovered several sites with palæolithic artefacts. He has worked, and directed the work of others, among tribal peoples. These peoples number about twenty-five millions, and he and his pupils have worked not only on their cultural anthropology but also on their demography. While a few tribal communities have been intensively studied, no comprehensive survey of this vast population exists, and Mr. Bose is keenly aware of the challenge which they offer to a State which has abjured imperialistic methods.

Mr. Bose has also worked on the cultural anthropology of more civilized sections of the Indian people, including certain of their festivals, and on the social changes which are now occurring in rural Bengal. Some of this work is available to readers of English in his book, "Cultural Anthropology", and in the pages of *Man in India*, of which he is an editor, but much of it has been published in Bengali. Like the English scientists of the seventeenth century, Indian scientists are now faced with the dilemma of publishing in an international language or attempting to educate their own countrymen. Mr. Bose, with his emphatic belief that anthropology begins at home, has often chosen the latter alternative, and for this reason readers of English may under-estimate his work. Mr. Bose has been a successful and much-loved teacher, and may therefore hope to succeed in his intention to establish a working relation between the Department and the universities.

Artificial Planet 2

THE United States *Pioneer* 4 space vehicle, launched from Cape Canaveral in Florida at 05.10 hr. U.T. on March 3, travelled past the Moon to become the second artificial planet of the Sun. The launching missile had four stages of propulsion: the first stage was the United States Army *Juno* 2 rocket, and the later stages were made up of clusters of solid-fuel rockets. The vehicle, conical in shape and with a mass of 13 lb., carried instruments to measure the intensity of the corpuscular radiation in the vicinity of the Earth, and a photo-electric sensor which, if the vehicle passed close enough, was to register light from the Moon. A radio transmitter with a frequency of 960 Mc./s. was also carried, with batteries to last for four days. By means of these signals the vehicle was successfully tracked by the Jodrell Bank radio telescope to a distance well beyond the Moon.

The vehicle, which attained an initial speed of 6·91 miles per second, passed the Moon at a distance of about 37,000 miles at 22.24 hr. U.T. on March 4, some 41 hr. after it was launched. It then flew on into an orbit around the Sun, and its distance from the Sun is expected to vary between 91·7 and 102 million miles. Its perihelion distance is, like that of Artificial Planet 1 (see *Nature*, **183**, 83; 1959), almost the same as that of the Earth, and the orbital plane is inclined at only a very small angle to the ecliptic. The orbital period about the Sun is expected to be 392 days; with the first perihelion on March 17.

New Laboratory for Research on Plutonium

THE Battelle Memorial Institute is to erect a new laboratory designed especially for studies of plutonium at its Nuclear Research Center outside Columbus, Ohio. It is hoped that the laboratory will be in operation by midsummer. It will be particularly well adapted to the study of plutonium as a reactor fuel material. This is a natural extension of the Institute's work in reactor and fuel element metallurgy, which dates back to 1942. The laboratory will be used by both governmental and industrial groups. Research at present planned for the laboratory will focus on alloys and compounds of plutonium, as well as plutonium itself. The new one-story building will provide 1,440 sq. ft. of space and will contain a variety of conventional and specialized equipment for the development of plutonium fuel elements. The research reactor, hot cells and critical assembly laboratory in operation at Battelle's Nuclear Center will provide supporting services and facilities for workers in the new plutonium laboratory.

Cyanamid European Research Institute, Geneva

CYANAMID, one of the leading chemical and pharmaceutical manufacturers of the United States, has recently completed plans for setting up a basic research laboratory, to be known as the Cyanamid European Research Institute, Inc., to be situated in Geneva. The new scientific centre, which is to employ British, French, German, Swiss and other European scientists, will be solely devoted to long-range research in the chemical and biological sciences. The Institute has acquired an 8½-acre tract of land in the Cologny section overlooking Lake Geneva. This property includes a large residence which will be converted and extended for use as laboratories.

Production and Marketing of Radioactive Isotopes in Britain

To meet the increasing demand for radioactive isotopes throughout the world, the U.K. Atomic Energy Authority has re-organized the production and marketing of isotopes, which has hitherto been shared between the Radiochemical Centre at Amersham and the Isotope Division at Harwell. It has been decided to widen the scope of the Radiochemical Centre, under the direction of Dr. W. P. Grove, to form a single comprehensive organization for producing and marketing all such isotopes. The Radiochemical Centre has its headquarters and principal laboratories at Amersham and will have irradiation facilities at Harwell and at other sites of the U.K. Atomic Energy Authority.

The re-organization is already effective, but users of radioisotopes should continue, for the time being, to order their requirements from Amersham or Harwell. Research into the properties of isotopes and new applications of them and their radiations will be continued at the Isotope Research Division, Harwell, and at the Wantage Radiation Laboratories. This Division will continue to operate the Isotope School; both the Radiochemical Centre and the Isotope Research Division will remain part of the Research Group of the Atomic Energy Authority.

Agricultural Aviation

THE use of aircraft in agriculture and forestry is by no means new and has made especially outstanding contributions to food output in newly developed areas. The aeroplane has also had some influence on traditional farming methods, and there is no doubt that the use of aircraft in farming will increase in the future. It is therefore appropriate that a new periodical, *Agricultural Aviation* (1, No. 1. Pp. 23. Published quarterly. Subscription rates per annum: Europe, 24*s*., 1,500 French francs; United States and Canada, 3.50 dollars. The Hague: E.A.V. v.d. Boschstraat 4, 1959), should be entirely devoted to this topic. It is published by the European Agricultural Aviation Centre at The Hague, but the contents are by no means limited to agricultural aviation in Europe. On the contrary, it should serve as a source of up-to-date information on a world-wide scale, and for this reason it is published in two editions, in English and French, respectively. The first issue contains two papers from member countries. One, by G. H. Brenchley, of the British National Agricultural Advisory Service, gives an account of trials carried out over the past two years in the control of potato blight by aerial spraying. The second, by G. Schumacher (Germany), concerns the control of leaf cast in common pine. There are also descriptions of new types of agricultural aircraft and equipment and extracts from recent agricultural aviation literature.

Selborne Society Library

THE Selborne Society has deposited its library, which was started in 1895, in the care of the Ealing Public Libraries, and thus made it available to all. The catalogue (pp. 34. Ealing: Central Library, 1958) has been compiled by the staff of the Ealing Reference Library and is arranged in six sections: manuscripts; editions of the "Natural History of Selborne"; other works by Gilbert White; works on Gilbert White and Selborne; books on natural history in general; and other books. It is hoped that the collection, already supplemented by the larger stock of Ealing Public Libraries, will be further augmented by additions from the Society and the public.

Transvaal Museum, Pretoria

THIS well-known Museum, in its annual report for the year ending March 31, 1958 (pp. 48. Pretoria: Transvaal Museum, 1958), records progress in its educational and scientific activities. Lack of space, though a familiar complaint, is now a very serious matter and constitutes a grave hindrance to the efficient functioning of the Museum. Several field trips have been undertaken during the year and in consequence much valuable material has accrued to the collections. The staff have been active in research and publication and continued to give freely of their time in lectures, talks and demonstrations to local cultural organizations. Temporary exhibitions were re-instituted during the year and placed on display each month in the entrance hall. Objects given to President Kruger, but not actually used by him, were transferred from the President's Residence and displayed in cases.

"Flora Europaea"

IN a short publication, Dr. V. H. Heywood has set out basic ideas and information relating to a projected new European Flora ("The Presentation of Taxonomic Information: A Short Guide for Contributors to Flora Europaea". Leicester University Press, 1958). In a foreword, Prof. T. G. Tutin, who is chairman of the Organizing and Editorial Committee, has explained that the main aim of "Flora Europaea" is to consolidate and correlate previous work. This comprises the studies and compilations of more than two centuries and involves contributions from some 20–30 countries. It is hoped to produce a well-balanced, critical survey, in which all relevant information concerning angiosperms, gymnosperms and pteridophytes will be assimilated and presented within a uniform framework. The Flora is intended to be of broad usefulness, not only for taxonomists, but also for other professional botanists, agronomists, foresters, and so on. It is expected that it will be completed within a period of about 12–15 years and that it will comprise three or four volumes. In the pamphlet under consideration, full information is given regarding standard procedures to be used in the preparation of the Flora. The sponsors are the Linnean Society of London, and the secretary of the Organizing and Editorial Committee is Dr. V. H. Heywood, curator of the Herbarium, University of Liverpool.

The Indian National Scientific Document Centre

THE demands on the services provided by the Indian National Scientific Document Centre, for which the Council of Scientific and Industrial Research provided Rs. 4,81,000, compared with Rs. 1,50,000 in 1953–54, increased by 15·2 per cent in 1957–58, and 6,202 out of 6,994 requests were met (Insdoc Report, 1957–58. Pp. ii+22. New Delhi: National Physical Laboratory of India, 1958). These included compilation of 126 bibliographies, 39 technical inquiries and the supply of copies of 5,290 articles, 44·2 per cent coming from Delhi libraries and 15·6 per cent from other Indian libraries. Requests were also received for 305 photocopies of diagrams for research papers, etc., and 441 translations were supplied out of 507 requested. The size of the Insdoc List of Current Scientific Literature has been increased and from January 1958 the *Bibliography of Scientific Publications of South and South East Asia* is being published monthly.

Snowdonia

"SNOWDONIA", issued for the National Parks Commission as National Parks Guide No. 2 (pp. xii+104+17 plates. London: H.M. Stationery Office, 1958. 5*s*. net), was prepared by the Snowdonia Park Joint Advisory Committee under the editorship of E. Vale. It includes descriptions of the geology of the Park by T. C. Miller, its plant life by Prof. P. W. Richards, and its fauna by Prof. F. W. R. Brambell, as well as notes on the principal antiquities within the Park, on mountaineering and on country-going and communications. There is also a full topographical description of the Park. The guide-book is well illustrated, and with a sufficiency of maps, an adequate bibliography, as well as lists of useful addresses, it should fill two important functions: the clarification of public understanding as to the purpose and functions of a national park; and the assistance of those who visit the Park. The National Parks Commission and the Snowdonia Park Joint Advisory Committee are to be congratulated on a first-rate piece of work, admirably designed for its purpose.

Availability of Technical Films used at the Geneva Conference

FORTY-FIVE technical motion pictures first shown last September in Geneva at the Second International Conference on the Peaceful Uses of Atomic Energy are now available for loan and sale from the U.S. Atomic Energy Commission. The 16-mm. films, most of which are in colour, cover major nuclear applications and research activities. They were sponsored by the Atomic Energy Commission, its industrial and university contractors and, in a few cases, by private industrial organizations. Most of the films will be lent on request to industry, advanced educational institutions, research organizations, Government agencies, etc., by the eleven film libraries of the Atomic Energy Commission, each of which serves a specific geographical area within the United States.

All forty-five Geneva films are also available for sale from the following sources: Byron, Inc., 1226 Wisconsin Avenue, N.W., Washington 7, D.C.; Capital Film Laboratories, Inc., 1905 Fairview Avenue, N.E., Washington 2, D.C.; Consolidated Film Industries, 959 Seward Street, Hollywood 38, California. The Washington and field libraries also have about seventy other, less technical, films appropriate and available for loan to schools, industry, and other audiences of laymen. Inquiries about the loan and sale of films to foreign users should be sent to the Public Information Service, U.S. Atomic Energy Commission, Washington 25, D.C. All films are available now in English for sale abroad, and will soon also be available in French, Spanish or Russian. An overseas loan programme is being arranged through the United States Information Agency.

Gas Chromatography

A SPECIAL group has been formed under the auspices of the Analytical Chemistry Section of the International Union of Pure and Applied Chemistry to make recommendations for a standard terminology in gas chromatography. The group consists of: Dr. D. Ambrose (Great Britain) (*chairman*), Dr. A. T. James (Great Britain), Prof. A. I. M. Keulemans (Netherlands), Dr. E. Kovats (Switzerland), Dr. R. Röck (Germany), Dr. C. Rouit (France) and Dr. F. H. Stross (United States). As a basis for their work, the group plans to take the two papers, "Presentation of Gas–Liquid Chromatographic Retention Data", by D. Ambrose, A. I. M. Keulemans and J. H. Purnell (*Analyt. Chem.*, 30, 1582; 1958), and "Terms and Units in Gas Chromatography", by H. W. Johnson and F. H. Stross (*ibid.*, 30, 1586; 1958). Comments about these papers or related subjects will be welcomed from those interested, and correspondence can be addressed to Dr. D. Ambrose, National Chemical Laboratory, Teddington, Middlesex, or to any member of the group.

Indian Society of Genetics and Plant Breeding

AT the nineteenth annual general meeting of the Indian Society of Genetics and Plant Breeding held on January 23, at New Delhi, the following were elected as office-bearers of the Society for 1959: *President*, Dr. R. H. Richharia; *Vice-Presidents*, Dr. A. B. Joshi, Prof. P. N. Bhaduri; *Secretary*, Dr. M. S. Swaminathan; *Treasurer*, Dr. N. L. Dhawan; *Editor*, Dr. B. P. Pal; *Councillors*, Prof. P. Maheshwari (Northern Zone), Dr. E. K. Janaki Ammal (Mid-Eastern Zone), Dr. S. K. Mukherjee (Eastern Zone), Dr. A. R. Gopal-Ayengar (Central Zone), Dr. T. R. Mehta (Western Zone), Dr. N. R. Bhat (Southern Zone). It was decided at the meeting that henceforth papers on animal genetics and breeding should be included within the scope of the *Indian Journal of Genetics and Plant Breeding.*

Postgraduate Awards in Agricultural Research

THE Agricultural Research Council has recently issued a useful booklet giving details of the Research Studentships and Fellowships which the Council is offering in 1959. The booklet also gives information about the openings in the agricultural research and advisory services. Two veterinary research fellowships, tenable for three years, will be open to workers holding a veterinary qualification who have had not less than three years experience in veterinary research, and three junior agricultural research fellowships, also tenable for three years, will be open to honours graduates with not less than three years postgraduate experience. In addition, the Council is again offering up to thirty postgraduate studentships in agricultural research including veterinary training grants, applications for which should reach the Council by March 31. Further information and a copy of the booklet can be obtained, free of charge, from the Secretary, Agricultural Research Council, Cunard Building, 15 Regent Street, London, S.W.1.

Eclipse of the Moon, March 24

THERE will be a partial eclipse of the Moon on March 24, visible at Greenwich. The circumstances are:

Moon enters penumbra	17h. 56m.
Moonrise at Greenwich	18h. 11m.
Moon enters umbra	19h. 16m.
Mid-eclipse	20h. 11m.
Moon leaves umbra	21h. 07m.
Moon leaves penumbra	22h. 27m.

The greatest fraction of the Moon's apparent diameter obscured by the umbra will be 0·27.

Announcements

DR. FRANCIS H. CARR, formerly chairman of British Drug Houses, Ltd., has been awarded the Society Medal for 1959 of the Society of Chemical Industry; this Medal is awarded not more than once every two years for conspicuous services to applied chemistry or to the Society.

LORD HAILSHAM, the Lord President of the Council, is to open the new Warren Spring Laboratory of the Department of Scientific and Industrial Research, at Stevenage, on June 29. Its initial programme will include work on mineral processing, the synthesis of oils and chemicals from carbon monoxide and hydrogen, and research aimed at the suppression of atmospheric pollution. Much of this work will be of a chemical engineering character and will require basic chemical engineering research to be undertaken in parallel with it. For the time being, research on atmospheric pollution will continue at the Atmospheric Pollution Division, Warren Spring Laboratory, River Way, East Greenwich, London, S.E.10.

A CONFERENCE on Silicon Carbide, sponsored by the U.S. Air Force Cambridge Research Center, will be held at John Hancock Hall, Boston, Mass., on April 2 and 3. Details can be obtained from the chairman, Dr. J. R. O'Connor, Materials Research Unit, Air Force Cambridge Research Center, Bedford, Mass.

THE symposium on vaccination against tuberculosis with non-living vaccines, which was to have been held in Florence during April 5–7 (see *Nature*, January 17, p. 154), has been postponed until September. Further information can be obtained from Prof. G. Buonomini, Centro per la Vaccinazione Antitubercolare, Universita di Pisa.

A SYMPOSIUM on Molecular Structure and Spectroscopy will be held at the Department of Physics and Astronomy, Ohio State University, during June 15–19. For further information, or for a copy of the programme when it becomes available, write to Prof. R. A. Oetjen, Department of Physics and Astronomy, Ohio State University, Columbus 10, Ohio.

THE annual meeting of the Air Pollution Control Association will be held at the Hotel Statler in Los Angeles, California, during June 22–26. At the technical sessions papers will be presented by outstanding authorities covering the control of air pollution. Proceedings, incorporating copies of all technical papers, will be published.

ERRATUM. A mistake was made in the manuscript of the communication entitled "Discrepancy between the Distributions of Iodine in Human Serum when estimated by Iodine-131 and Iodine-127" by Drs. S. C. Werner and R. J. Block (*Nature*, February 7. p. 406); in Table 1, col. 2, for "33" read "3".

DARWIN, WALLACE AND LINNÆUS CELEBRATIONS IN SINGAPORE

A CONGRESS was held in Singapore during December 2–9 to celebrate "the Centenary of the formulation of the theory of Evolution by Charles Darwin and Alfred Russel Wallace and the Bicentenary of the publication of the tenth edition of the 'Systema Naturæ' by Linnæus".

It was particularly fitting that this Congress should have been held in Singapore for, although it honoured equally the works of Linnæus, Charles Darwin and Alfred Russel Wallace, it directed special attention to the work of Wallace, who was one of the greatest biologists ever to have worked in south-east Asia. Although it was inspired and run by a small body of organizers without any form of public recognition, and although it was financed solely by response to personal appeals, the Congress achieved international status and standards. Much credit goes to the organizers, the sponsors, and all who participated.

Twenty-three scientists visited Malaya to participate in the Congress, from Britain, Holland, India, Ceylon, Thailand, Sarawak, Hong Kong, Formosa, Australia, Hawaii, Korea and the United States. These joined with Malayan and Singaporean scientists to form a group of some sixty persons who contributed scientific papers, exhibitions, evening discourses and film shows, and attended excursions into primary forest and mangrove swamps.

Nearly six hundred members were enrolled, and attendances at meetings were consistently high. The papers delivered were of high quality and, due to good chairmanship, the meetings kept to the time programme, and adequate time was available for some stimulating discussions.

The Chief Minister of Singapore, Tun Lim Yew Hock, welcomed the visiting scientists and members of the Congress at an inaugural ceremony, which was held at King Edward VII Hall. Prof. J. B. S. Haldane (Calcutta) was then installed as president of the Congress by the vice-chancellor of the University of Malaya, Dr. A. Oppenheim. Prof. Haldane then delivered his presidential address—"The Theory of Natural Selection To-day"—to a large and colourful gathering of members and distinguished guests. The president emphasized the stimuli gained by Linnæus, Darwin and Wallace through working in peripheral areas where lack of knowledge was a challenge. He suggested that the next major biological advance may well come for similar reasons from peripheral places such as Singapore, or Calcutta, where this challenge still remains and where the lack of complex scientific apparatus drives biologists into different and long-neglected fields of research [see p. 710 of this issue of *Nature*].

The first scientific session constituted a general introduction to the Indo-Malayan Region. R. Ho (Malaya) reviewed the geological history and present geographical features of the region; E. J. H. Corner (Britain), official representative of the Royal Society, directed attention to the need for work on the rain forests of Malaysia before it was too late, and illustrated the inadequacy of our present knowledge of the area by a series of fundamental questions that remain unanswered as yet. Tom Harrisson (Sarawak) proceeded to review the changes that have occurred in Sarawak since Wallace's time, some of which were attributable to Wallace himself, such as the regrettable decimation of the orang-utan.

The papers presented in the section on evolution reflected the broad spectrum of modern non-experimental evolutionary studies. The phylogeny of fishes was considered by A. Fraser-Brunner (Singapore), of lamellibranchs by R. D. Purchon (Singapore), and of the agnathan head by R. Strahan (Hong Kong). Problems of comparative anatomy were dealt with by D. D. Davis (Chicago) and D. Barker (Hong Kong). Zoogeography was represented by a paper by J. L. Gressitt (Honolulu). Perhaps most significant was the strong emphasis on the operation of evolutionary mechanisms within small natural populations, representing promising attempts to document from Nature the mathematical models of Fisher and Wright and the laboratory experiments of Dobzhansky and others. Of a total of nine papers, three—by G. S. Carter (England), H. G. Andrewartha (Australia) and W. S. S. Van Benthem Jutting (Holland)—were concerned with one aspect or another of this important problem.

The session on parasitology and entomology opened with a review by A. A. Sandosham (Singapore) of the evolution of the parasitic mode of life. R. Hoeppli (Singapore) gave an entertaining review of the growth of knowledge of tapeworms, illustrating the value of the sadly neglected historical approach. J. R. Audy (Malaya) discussed evolution of parasitism in trombiculid mites; W. W. Macdonald (Malaya) reviewed the distribution and some evolutionary aspects of Malayan mosquitoes with special reference to breeding places, some species being closely associated with man through adoption of man-made breeding places. This made an interesting comparison with the discussion by L. W. Quate (Honolulu) of different patterns of dispersal and of evolution in the islands of Micronesia by two families of Diptera—empids, largely airborne, and psychodids, largely dispersed by man. J. R. Audy, in a second paper, noted that many parasites are habitat-specific rather than host-specific, or depended for transfer on particular features of host-behaviour, and stressed the value of parasites as 'ecological labels' to give ecological information about their hosts. Finally, Kim Hon-Kyu (Korea) described the life-history and host relationships of a wasp parasitic on a moth which is a potential source of silk in Korea.

At the session on zoogeography, Wallace's Line was not regarded as constituting a significant frontier between two distinct faunal areas either by J. L. Gressitt (Honolulu), who considered the insects, or by L. G. Brongersma (Holland), who has studied the reptiles. In both cases transition was noted rather than abrupt change. H. E. McClure (Malaya) discussed the migration of birds in the Far East and indicated the known flight routes over a wide area. In the absence of any programme of ringing of birds, little is known of the distances travelled by individuals.

Of the six papers presented on terrestrial ecology, three were concerned with particular ecological phenomena or particular animal species and the others with the broader point of view usually called 'natural history'. In the animated discussions that followed papers and occurred informally at other times, the most notable feature was a general agreement that the fauna of the tropical rain forest, because of its extreme ecological complexity, is still so poorly understood that it can best be studied from the 'natural history' point of view, for the present leaving precise quantitative studies and intensive testing of ecological principles to workers in simpler environments in other parts of the world.

The first two papers in the session on freshwater ecology, by W. S. S. van Benthem Jutting (Holland) and D. S. Johnson (Singapore), dealt with aspects of the distribution of non-marine molluscs of the Mollucas and of Indo-Pacific freshwater organisms, respectively. The latter paper, which queried the validity of the concept of a separate oriental region, provoked an interesting discussion. A paper on productivity of fishponds and similar bodies of water by G. R. Fish (Malaya) elicited a lively and informative discussion. Other papers included colonization of freshwater habitats by aquatic insects by C. N. Fernando (Ceylon) and the study of breathing behaviour of salamanders and of the climbing perch by H. Spurway (Calcutta).

The genetics section opened with four papers on human polymorphism in South-east Asia. F. Vella (Singapore) described abnormal hæmoglobins in local Chinese, Indians, Malays and others; thalassæmia was not uncommon in Chinese and Malays, sometimes associated with abnormal hæmoglobins. I. Polunin (Singapore) discussed wide variations in blood-group frequencies in different settlements of the same aboriginal tribe, probably due to genetic drift. D. C. Rife (Bangkok) presented dermatoglyphic evidence that Thai people are closely related to Chinese, while E. McEvoy-Bowe (Singapore) described his work on β-amino-*iso*butyric acid excretion in local peoples and gave details of his useful new method for the accurate estimation of urinary amino-acids in chromatograms.

Among later papers, that of C. F. Hickling aroused special interest. He described hybridization experiments with important food-fish of the *Tilapia mossambica* group. Some crosses led to all-male F_1 progeny with marked hybrid vigour, growing about twice as fast as the parent stocks. S. K. Roy (Calcutta) described the wide polymorphism of Indian cattle and buffaloes, with special reference to nipple number. A. G. Searle (Singapore) showed that threshold characters were remarkably common in local wild mice as well as in domesticated animals. He suggested that anencephaly in humans was also due to a threshold mechanism. The last contribution, by Helen Spurway and A. Kumar (Calcutta), on variation under domestication, contained some intriguing suggestions; for example, that "we have not domesticated plants, but they have domesticated us". The chairman (J. B. S. Haldane, Calcutta), in summing up, pointed out the great opportunities in tropical countries for work on human genetics and on cultivated plants and animals in the early stages of domestication.

The section on anthropology covered a wide range of subjects. V. Thambipillai (Singapore) described the physical types of man now living in Malaya, while G. C. Whittow (Singapore) and T. S. Lee (Singapore) both discussed physiological adaptations to life in the humid tropics. I. Polunin (Singapore) concluded that the falling birth-rate in the Muruts of North Borneo may arise chiefly from infectious disease following pregnancy. Tom Harrisson (Sarawak), drawing vividly on his own experiences, gave a stimulating review of the basic problems of living in the jungle. M. Benanzio (Singapore) commented on the high incidence of 'Mongolian spot' in certain populations in Sumatra.

The most interesting contribution in the session on systematics was perhaps the description and discussion by D. Barker (Hong Kong) of the interesting crustacean *Thermosbaena mirabilis*, representative of the small and often neglected order Thermosbaenacea. Further papers were presented by D. S. Johnson (Singapore), P. J. van der Feen (Holland) and L. G. Brongersma (Holland) on a variety of topics ranging from variation in freshwater prawns to the fauna of New Guinea.

E. J. H. Corner (Britain) opened the botanical session and concluded from an attempt to reconstruct the evolution of tropical broad-leaved forest that it was perfected at the beginning of the Cretaceous period before there were, apparently, modern birds and mammals such as now use it. H. B. Gilliland (Singapore) directed attention to the importance of the orchid seedling, with its changes in symmetry, to plant morphology. J. Wyatt-Smith (Malaya) suggested that the vegetation of Pulau Pangkor in the Malacca Straits was destroyed by the eruption of the Toba Lake volcano and that the new flora is of oceanic type, depending mainly on wind- or animal-dispersal of seeds. E. A. Rosenquist (Malaya) discussed the physiology and genetics of palms; G. A. Prowse (Malaya) described new species of Flagellata which provide important sources of fish-food in the fish ponds in which several are characteristic. Yen Yo-Min (Singapore) described the discovery of six *Cercospora* diseases on sugar cane in Formosa. S. K. Roy (Calcutta) gave an account of variation of leaves on the same plant in *Nyctanthes arbor-tristis*. A. Johnson (Singapore) discussed the distribution of Malayan mosses and green seaweeds, an important extension of Malaysian phytogeography. Finally, A. Santiago (Malaya) spoke of the importance of agricultural genetics in applied botany and the shortcomings of reliance on vegetative propagation.

The week-end excursion to Bukit Timah gave a valuable introduction to Malayan rain forest for those to whom it was new, since Bukit Timah is a most important type locality for plants and animals in Malaysia. This is now a carefully protected nature reserve of some 150 acres.

An all-day excursion began with exploration of the mangrove swamp in the Pandan Nature Reserve. The party saw many interesting species, including some large mud-skippers (*Periophthalmus*), one of which was being killed and consumed by the common dog-faced water snake (*Cerberus*).

The scientists visiting Malaya were entertained at a cocktail party at the residence of the chairman of the Organizing Committee on the first evening. On subsequent evenings there was a diversity of public functions, which were particularly appreciated by the many local members who were not free earlier in the day. There were public lectures by J. B. S. Haldane (Calcutta), J. R. Hendrickson (Singapore) and by H. Munro Fox (Britain), the representative to the Congress from the British Association for the Advancement of Science. There were two evenings of film shows; the first consisted of films taken in Sarawak and presented with a lively running commentary by Tom Harrisson (Sarawak), while the second included films taken in New Guinea and presented personally by L. G. Brongersma (Holland), one taken in North Borneo and presented personally by I. Polunin (Singapore), and one by the Malayan Film Unit, which was introduced by R. D. Purchon (Singapore).

The British Council prepared a photographic exhibition of Darwiniana specially for the Congress, and this was displayed in the Art Museum of the University of Malaya, where it was the object of considerable interest. The exhibition was afterwards displayed in Kuala Lumpur and, so that the maximum benefit should be gained from its preparation, it was then sent on tour; part was sent to Colombo for the meeting of the Ceylon Association for the Advancement of Science and the remainder was sent first to Kuala Lumpur and then to Bangkok. On its return it will be presented to the Department of Zoology, University of Malaya, through the generosity of the British Council.

A bibliographic exhibition was organized by the Foreign Service of the United States and consisted of about three hundred biological publications the majority of which were sent from America specially for the Congress, and the greater part of which has been most generously presented to the library of the University of Malaya. This exhibition was augmented by a smaller number of British works, loaned for the occasion by the Singapore agents of various British publishing houses.

After the Congress, an excursion lasting a fortnight was conducted which traversed the west-coast districts of Malaya as far as Perlis. Special attention was paid to freshwater habitats; the variety observed ranging from rice-fields to torrent-streams, and from acid blackwaters to limestone pools. In addition, visits were made to the Fish Culture Research Station at Batu Berendam, Malacca (*Nature*, 183, 287; 1959); to the Rubber Research Institute and the Institute for Medical Research at Kuala Lumpur; and to the Fisheries Department and the Bayan Lepas Experimental Farm at Penang. The opportunity was taken to visit and collect from a number of limestone hills and caves.

The post-Congressional field trip to the King George V National Park in the depths of Pahang brought together nine biologists from four continents, whose interests ranged through taxonomy, zoogeography, ecology and evolution. The base of the party was at Kuala Tahan, where they lived in a lodge of the National Park, with adjacent facilities in the Forest Research Laboratory of the Department of Zoology, University of Malaya. The party spent six days walking and collecting through a number of different types of vegetation. They inspected the pattern of quadrats laid out by the Department of Zoology as a part of its long-term programme of ecological research in the jungle. Valuable suggestions were received from the visiting scientists regarding methods of approach and priorities in this programme.

Arrangements were made for some of the visitors to lecture at Kuala Lumpur in the Federation of Malaya, to widen the impact of the Congress. Prof. J. B. S. Haldane gave the substance of his lecture on natural selection and genetics, previously delivered in Singapore, to a special meeting of the Malayan Nature Society. In addition, the Malayan Scientific Association convened a special meeting, at which H. Waring (Australia) discussed the studies, which he had previously presented in Singapore, on the marsupial quokka. H. G. Andrewartha (Australia) described some extremely interesting experiments on mice still in progress in Adelaide. These bear directly on intra-specific elements influencing reproduction and may help to interpret the regulation of population densities. L. G. Brongersma showed and commented on the ciné film of his zoological field work in Dutch New Guinea. The visitors saw the forest reserves and the laboratories of the Institute for Medical Research and of the Rubber Research Institute.

The proceedings of the Congress were covered by the Malayan Film Unit, and it is anticipated that a documentary film will be released in the near future.

Any credit balance remaining in the hands of the chairman of the Organizing Committee will be applied as an endowment to provide a book prize in the University of Malaya as a permanent reminder of this very successful Congress and the events which it honoured. Since the Congress was originally conceived to pay public tribute to the works of Alfred Russel Wallace in Malaysia, it is fitting that this should be known as the 'Wallace Prize'. A few copies of the abstracts of papers and of the programme are available (3*s*. and 2*s*., respectively, including postage).

The scientific papers will be published in full in book form. Applications for the abstracts and programme and advance orders for the scientific papers should be sent to Prof. R. D. Purchon, Department of Zoology, University of Malaya.

R. D. PURCHON

THE HAFFKINE INSTITUTE, BOMBAY

DIAMOND JUBILEE

ON January 10 the Haffkine Institute in Bombay celebrated sixty years of service in medical research. At the opening ceremony, which was attended by scientists from India and from other countries, the President of the Republic of India, Dr. Rajendra Prasad, said that Dr. W. M. W. Haffkine, founder of the Institute, had built up a tradition which the modern scientific world could best honour by emulation. It might have been a coincidence that a scientist born in Russia and trained in France happened to be in India, when he was assigned the urgent task of preventing plague from taking a heavy toll of lives; but, the President continued, it served to illustrate that scientific advance of all types called for international collaboration. The Bombay Health Minister, welcoming the delegates, announced that the Government of India had given Rs. 300,000 for the expansion of the Institute and that the Government of Bombay had decided to create a special fund for its development.

Waldemar Mordecai Wolff Haffkine was born of Jewish parents at Odessa on March 15, 1860. He obtained his doctorate in science at the University of Odessa in 1884 and, after working with the physiologist, Moritz Schiff, at Geneva, went to the Pasteur Institute at Paris in 1889 as *préparateur*. Pasteur had introduced vaccine treatment for fowl cholera, and Haffkine in 1892 developed the first successful vaccine against human cholera. Through the influence of Lord Dufferin, British Ambassador at Paris and former Viceroy of India, Haffkine was sent to Calcutta in 1893. The results of his anti-cholera inoculations were so encouraging that the Government of India in October 1896 transferred him to Bombay, where plague had broken out. Haffkine began work at the Petit Laboratory of Grant Medical College; his accommodation consisted of one room and a corridor, and his staff numbered one clerk and three peons, none of whom knew anything of bacteriological methods and had to be trained by him. He succeeded in preparing a prophylactic plague vaccine from pure cultures, which he proved to be harmless on his own person. Its first trial on a plague-stricken community was made in the Bombay House of Correction at Byculla in January 1897. Of 172 untreated prisoners, twelve developed the disease and six died; of 147 inoculated persons, two contracted plague, but none died. During the season at which the plague was prevalent, up to October 1897, 8,142 inhabitants of Bombay applied for inoculation. In April 1897 Haffkine moved his laboratory to a house on Malabar Hill, and in November made another move to premises in Nepean Sea Road, provided by the municipality.

In the following February the Aga Khan placed at his disposal a large house, Khushru Lodge, in Nesbit Lane, Mazagaon. When orders for the prophylactic vaccine began to pour in from all parts of the world, the laboratory became an Imperial concern, and larger premises had to be found at the Old Government House, Parel. The new laboratory was formally opened by the Governor of Bombay, Lord Sandhurst, on August 10, 1899, when Major W. B. Bannerman gave an account of the prophylactic and its action. Three years later Haffkine was appointed director of the Biological Laboratory at Calcutta. He left India in 1916 and lived in retirement at Boulogne-sur-Seine and at Lausanne, where he died on October 26, 1930, aged seventy. A charming, kindly and enthusiastic personality, an accomplished linguist, and a 'bacteriological wizard', Haffkine never married. He was created C.I.E. in 1917.

In 1925 the Government of Bombay decided to call the bacteriological laboratory at Parel 'The Haffkine Institute' to commemorate the name of its founder (*Nature*, 116, 551; 1925).

To-day, this Institute is the largest research institution of its kind not only in India but also in the East. It has a technical staff of more than one hundred scientists and a subordinate staff of more than five hundred workers, supervized by eight assistant directors and one director, Dr. H. I. Jhala. Its functions are medical research, training of research workers, supply of vital biologicals and diagnostic aids. The vaccine department collaborates with the Plague Committee of the Indian Council of Medical Research in research on plague, and with the World Health Organization in standardization of cholera vaccine. The department of virus diseases acts as a laboratory for an influenza centre in India, in the network of World Health Organization laboratories attached to the World Influenza Centre, London. The Institute is affiliated to the University of Bombay for degrees of M.Sc. and Ph.D. in microbiology, biochemistry, organic chemistry, pharmacology, pathology, bacteriology and zoology. W. R. Bett

UNIVERSITY OF OXFORD TANGANYIKA EXPEDITION

A PARTY from the University of Oxford, with the support of the Government of Tanganyika, made a preliminary scientific survey of the Kungwe-Mahali Mountains on the eastern shore of Lake Tanganyika (longitude 30° E., latitude 6° S.) during July–October 1958.

A herbarium collection was made of the plants of the southern two-thirds of the peninsula by J. G. B. Newbould, T. G. Jefford and B. E. Juniper, of the Botany School, Oxford. This is the first major collection from the area. The material will be assembled and identified at the Royal Botanic Gardens, Kew, for inclusion in the Flora of East Africa. In addition, live orchids were collected and are now in the orchid houses at Kew. Colour photographs were taken of the principal vegetation zones of the area and of many species of flowering plants.

H. F. Lamprey and A. J. Mence, of the Game Department, Tanganyika, and S. Ulfstrand, of the Zoologiska Institution, Lund, made a collection of birds and small mammals. This includes 305 birds, comprising about 135 species. Another 100 species were identified by sight. Among the birds collected were *Campethera taeniolaema* and *Psalidoprocne chalybea*. These records extend considerably the known ranges of these birds. One specimen, a woodpecker of the genus *Campethera*, with affinities to *C. abingoni*, fits no described species and still remains to be identified.

Among the small mammals, which are at present being examined at the British Museum, is the second specimen from Tanganyika of the ground squirrel genus *Protoxerus*.

A survey was also made of the isolated chimpanzee population. When further information is available about the flora, particularly of the forest species, further conclusions may be drawn about the affinities this region has with West Africa. These affinities are already apparent to a certain extent in the records of chimpanzees and *Protoxerus*.

T. E. Stevens completed a geological survey of the south, centre and west of the Mahali Range. Several interesting geomorphological features were observed and a collection of rock specimens was made which will be examined in the Department of Geology, Oxford.

P. L. Simkin, of the University of Oxford, and A. Roggenkämper, of the University of Bonn, made some preliminary anthropological observations among the Waholoholo of the Mahali Mountains. A census was made of the population of some of the villages south of Mount Kungwe. Studies were also made of social habits and ceremonies, witchcraft and beliefs, with particular reference to the worship of the god Kungwe.

More than 7,000 ft. of 16-mm. ciné film was exposed during the field work of the expedition and on aspects of the village life of the Waholoholo. Songs, musical instruments, drumming, dances and conversation of the Waholoholo, bird song and animal noises were recorded on tape by A. Roggenkämper.

A second expedition to the same area with a different emphasis is being planned for 1959. It will include a zoologist to work on the freshwater fauna and another zoologist, three geologists, one botanist, and probably a medical man and a soil scientist.

B. E. JUNIPER

RADIO TRANSMISSION BY WAVE-GUIDE

THE continually increasing demand for radio frequencies for new and expanding services makes it necessary to review periodically the possibilities of any alternatives to free-space radio circuits. The installation of the trans-Atlantic coaxial cable carrying a large number of telephone circuits has been an outstanding success; and wide-band coaxial cables are in use as alternatives to radio links for conveying television signals over shorter distances. But coaxial cables, using the materials and techniques at present available, are limited to an upper working frequency of about 25 Mc./s., beyond which the attenuation and phase characteristics become unacceptable. With the development in recent years of the technique of generation and reception of ever higher radio-frequencies, corresponding to wave-lengths down to a few millimetres, the hollow tubular wave-guide has become a serious competitor of the coaxial cable. It was therefore very timely that a well-attended convention on "Long-distance Transmission by Wave-guide" was held on January 29 and 30 by the Radio and Telecommunication Section of the Institution of Electrical Engineers.

At the opening session of the convention, Prof. H. E. M. Barlow gave a most interesting and lucid introductory survey of the present technique of guiding radio waves along the outside surface of a single wire and along the inside of a hollow tube. His presentation included demonstrations of the configuration of the electric field both along a wire and inside a tube using a neon gas discharge, of the effect of a dielectric coating on a wire to counteract the radiation from it, and of the manner in which transducers can be arranged to connect cables to wave-guides. One of the great advantages of a copper tubular guide, about 2 in. in diameter, is that its attenuation for circular electric modes decreases with increase of frequency of the radio waves. For example, at a frequency of 40 Gc./s., corresponding to a wave-length of about 7 mm., the attenuation of the guide is about 6 decibels per mile.

At the remaining five sessions of the Convention more than thirty papers were presented; many of these were of a detailed technical nature and they illustrated the advance which is being made in this field in Great Britain and other countries. Some of these papers dealt with both theoretical and practical aspects of avoiding spurious modes of transmission of radio waves in the tube, and the need to discriminate carefully in the conduct of measurements on the characteristics of the guide. Special microwave equipment is being developed to generate the very short waves involved, and particularly to couple the source to the guide, so that waves of the desired mode may be launched with the minimum loss of energy. The last session was devoted to a discussion of the practical possibilities of wave-guides for long-distance transmission, including the economic aspects of such communication systems. The speakers here stressed the fact that not only must such systems have a high degree of stability, but that, so far as possible, they must also be compatible with existing signalling networks as regards facilities for the insertion and extraction of signals at terminals and intermediate points.

On January 31, demonstrations were given of a variety of experiments using millimetre waves associated with tubular wave-guides in the Electrical Engineering Department of University College, London, and at the premises of Standard Telecommunication Laboratories, Ltd., at Watton-at-Stone, near Stevenage.

The text of all papers presented at the convention, together with the associated discussion, will be published in a Supplement to Part *B* of the *Proceedings of the Institution of Electrical Engineers*.

HILL FARMING RESEARCH ORGANIZATION

REPORT FOR 1954–58

THE scientific investigation of the problems of hill farming remained largely sporadic and unco-ordinated until it became recognized that this sector of the British agricultural industry is a distinctive form of land-use, based on complex and varying interactions of plant and animal communities which in themselves merit concerted programmes of research to define them more clearly and to attack their major problems. This concept provides the background to the establishment in 1954 of a central research organization and to its objectives and activities; these are clearly and succinctly described in the first report of the Hill Farming Research Organization*.

The extensive distribution of the hill farming areas in Great Britain, and the great ranges in environmental conditions and husbandry systems offer wide scope for study; three factors have tended to restrict,

---

* Hill Farming Research Organization. First Report, 1954–58. Pp. 88. (Edinburgh: Hill Farming Research Organization, 1958.)

as yet, development of the Organization's work. In the first place, any investigations of such a complex must be on a long-term basis; a small, though full-time, staff can only encompass narrow segments of the field, and in some four years their work can only be preliminary. Secondly, the work must be biased towards 'field' studies, with the niceties and precision of replicated experimentation largely sacrificed. Thirdly, the Organization's three research stations, to the resources of which much of the programme has had to be geared, were inherited from an earlier régime of separate interests in hill farming problems as presented in the areas of the three Scottish agricultural colleges.

At Glensaugh, in Kincardineshire, the basic Blackface sheep stock, on predominantly heather vegetation, is managed according to the custom of the north-eastern counties of Scotland; studies on the dentition and on winter feeding of sheep are in progress, as well as on different breeds and crosses of beef cattle in relation to prolificacy and growth of calves. Lephinmore, in the Cowal peninsula of Argyllshire, provides a varied hill ground in an area of high rainfall, relict from afforestation of plantable land, and thus having peculiar management problems for its Blackface sheep stocks. Sourhope, in Roxburghshire, is the main station for work on Cheviot sheep under conditions reasonably typical of the Cheviot hill areas; investigations on mixed grazing with cattle and sheep had begun in 1951, and others on controlled grazing and on the treatment of cobalt deficiency have since been added.

Animal studies are in two main groups, related respectively to breeding and nutrition. In the former, comparisons of breed and strain are being made with the Blackface and Cheviot breed types, while in respect of the latter, the principal emphasis has been on problems of the nutritional status of hill sheep in winter; various methods and forms of supplementary winter feeding are being examined, responses in the mortality and growth of lambs observed, and differences in feeding habits noted. Particular attention is being given to the plane of nutrition, and methods of 'wintering', of flock replacements during their first winter.

The botanical work is described in more detail. Studies on management involve the effects of burning, drainage, surface seeding and cultivations, sod-seeding, heather grazing, fertilizer treatments, and bracken control. The great significance of the ecological aspects of the hill vegetation influences the investigations on plant communities and their species components and ecotypes; investigations in these fields are being conducted in a wider range of localities and environments beyond those presented in the Organization's own farms. Exploratory studies on the sheep grazing behaviour and preferences in relation to plant communities are being made at Sourhope.

A list of publications is given, and almost by way of appendixes, there are three occasional papers comprising reports on surveys of management systems in Blackface sheep in the north-east of Scotland (with special reference to the incidence of breakdown of incisor teeth with age), and of Border Cheviot sheep, and a short note on the effects of August treatments of a pasture sward on its subsequent yields in autumn, winter and spring.

J. E. NICHOLS

ULTRA-VIOLET CARCINOGENESIS IN ALBINO AND PIGMENTED MICE RECEIVING FUROCOUMARINS: PSORALEN AND 8-METHOXYPSORALEN

By M. A. PATHAK, PROFS. F. DANIELS, jun., C. E. HOPKINS and T. B. FITZPATRICK

University of Oregon Medical School, Portland, Oregon

EPIDEMIOLOGICAL evidence clearly implicates solar radiation as a factor in the induction of human skin cancer[1,2]. A factor which appears to protect man from carcinoma induced by exposure to solar radiation is melanin pigment, the darkly pigmented peoples having a markedly reduced incidence of carcinoma of the exposed areas[2–5]. The generalized human albino living in the tropics almost invariably develops squamous and basal cell carcinoma of the exposed surfaces[4]. Similarly, the fair-skinned Caucasians who easily become sunburnt and have a tendency for freckling have a higher incidence of carcinoma of the exposed areas than persons who tan readily[6,7]. The carcinogenicity of ultra-violet irradiation in albino mice has been established by many investigators[3,8–12] and has therefore provided an excellent experimental tool for studying the process of skin carcinogenesis.

Naturally occurring furocoumarins (psoralen, 8-methoxypsoralen or methoxsalen) have recently been used for augmenting pigmentation of human skin following irradiation with long-wave ultra-violet light. This raised the question whether these photoactive compounds might alter the incidence of ultra-violet carcinogenesis. O'Neal and Griffin[13] initiated studies on 8-methoxypsoralen and its effect on ultra-violet carcinogenesis in albino mice. Their initial report indicated that the final incidence of ear tumours induced by ultra-violet irradiation ($15 \cdot 2$ to $17 \cdot 5 \times 10^{8}$ ergs/cm.^{2} of short and medium range up to 3200 A.) in mice receiving 8-methoxypsoralen orally (0·5 gm./kgm. diet) was considerably less than that of control mice, evidence suggesting that this photoactive agent had a 'protective' effect against ultra-violet carcinogenesis. The extent of protection afforded by this compound appeared to be proportional to its concentration in diet up to an optimal level of 0·5 gm./kgm. diet. They found, however, in the same experiment that intraperitoneal administration of 8-methoxypsoralen (0·4 mgm./mouse/day) appeared to increase tumour incidence. Whether the discrepant effects of oral and intraperitoneal administration were related to a difference in the dose or in the route of administration was not resolved.

The present study was undertaken to determine: (*a*) whether 8-methoxypsoralen and psoralen (furo-2′,3′: 6,7-coumarin) when given in oral form protected or otherwise affected the ultra-violet carcinogenesis in albino and pigmented mice; (*b*) if the findings of O'Neal and Griffin[13] could be explained on the basis of differences between the oral and intraperitoneal route of administration; (*c*) the effect of a second furocoumarin, psoralen, as compared to 8-methoxypsoralen (Fowlks *et al.*[14], Pathak and Fitzpatrick[15] and other investigators[16] have reported psoralen to be the most potent photoactive naturally occurring furocoumarin); (*d*) the role of melanin pigment in the skin in ultra-violet carcinogenesis.

Three strains of female mice were used: Swiss strain albino mice, strain *C57BL/6* with black ears, black eyes and hair, and a deep brown strain *C57Br/cd* (Jackson Memorial Laboratory, Bar Harbor, Maine). An ultra-violet irradiation chamber was constructed with two *UA*3 General Electric 'Uviarc' lamps mounted adjacently in aluminium reflectors[13]. The mice were exposed to the total ultra-violet spectrum (mostly short and middle ultra-violet at a distance of 50 cm.). Intensity of illumination under the lamp in a 2 sq. ft. area was determined every 4 weeks by photolysis of uranyl oxalate solutions according to the method of Leighton and Forbes[17]. Quantum yield for the entire spectrum was taken as 0·57 φ. To prevent huddling or movements of mice during irradiation special cages holding each mouse in a separate compartment were used[10,12,13].

Mice 8–10 weeks old with comparable average weight within each strain were randomly divided into cage groups of 20 each. Twenty-eight groups were used: twelve in the albino series, eight in *C57BL/6* strain and eight in *C57Br/cd* strain. Each group received ultra-violet irradiation for six days a week at the rate of $2{\cdot}9 \times 10^{4}$ ergs/cm.^{2}/sec. Total ultra-violet irradiation received by each group was $14{\cdot}8 \times 10^{8}$ ergs/cm.^{2} delivered in 850 min.[12]. Irradiation was discontinued after 110 days for albino mice and after 120 days for pigmented mice, following which the observations for tumour incidence were continued for a total of 260 days. Changes in temperature during irradiation were minimized by slow circulation of air from a revolving electric fan. To minimize the possibility of photo-reactivation the animals were housed in a windowless, dark room.

Because the findings of O'Neal and Griffin[13] might be explained by a biphasic response with protection from carcinogenesis by the small doses of 8-methoxypsoralen received in the dietary group, and potentiation by the large doses given in the intraperitoneal group, only oral doses were used in this study. Administration of drugs was carried out by addition of 8-methoxypsoralen or psoralen in a concentration of 0·5 gm. per kgm. of powdered 'Purina Laboratory Chow', which was mixed in a revolving ball mill for 12 hr. Each day's food intake was recorded for each group receiving drugs in the diet. A second method consisted of measured quantities of drug given individually to each mouse by oral feeding from a tuberculin syringe with an attached 18 gauge, semi-curved metal tube 1 in. long. It was possible by slowly inserting the bent tube into the mouth to administer 0·05 ml. suspension of either psoralen or 8-methoxypsoralen prepared in 0·5 per cent gum acacia solution. Wood's light examination of the mice after feeding determined that no spillage of fluorescent compounds had occurred around the mouth. Preliminary tests had indicated that, with oral feeding, the furocoumarins developed their highest concentration in the blood in 1¼ hr. Ultra-violet irradiation was therefore given at this time-interval following drug administration. The dose schedule, as shown below, included the range of levels used by O'Neal and Griffin on intraperitoneal dose and also 0·01 mgm., the equivalent of a 20–30 mgm. dose of the drugs in man. Administration of drug was discontinued after 120 days. The experimental schedule is given in Table 1.

Table 1. EXPERIMENTAL GROUPS AND DOSE SCHEDULE

Dose	Mouse strains and group numbers		
	Swiss Albino	Brown *C57Br/cd*	Black *C57BL/6*
Controls (no drug)	1, 2	13	21
8-Methoxypsoralen mgm./mouse/day			
Oral—0·01	3	14	22
,, 0·04	4	15	23
,, 0·16	5		
,, 0·64	6	16	24
Dietary 1·7	7	17	25
Psoralen mgm./mouse/day			
Oral—0·01	8	18	26
,, 0·04	9		
,, 0·16	10		
,, 0·64	11	19	27
Dietary 1·7	12	20	28

Each mouse was tagged for individual identification in the observation of effects of irradiation. The mice were examined separately by three observers (M. P., T. B. F. and F. D.) every ten days. The last two observers did not know the identity of the groups until the completion of the experiment. A five-point grading system was used: normal ear, 0; inflammatory response without nodules, 1; suspicious nodules, 2; definite nodule suggestive of cancer, 3; definite tumour, 4. Right and left ear were recorded separately for each mouse. A mouse graded 3 or 4 on either ear by at least two observers was recorded as having a tumour. The analysis is based on the number of mice having tumours and not the total number of tumours. Mice dying after 120 days of irradiation with grades 0, 1 and 2 were considered to have no tumour. The final tumour incidence is expressed as a percentage of the initial number of mice in each group.

Within a week after the beginning of irradiation both the albino and the pigmented mice showed erythema and scaling on the ears. In about three weeks the scale had come loose and ears showed thickening. Both types of pigmented mice showed increased pigmentation of the ears and tail region. This pigmentation was greater in the mice receiving the drugs. Mice receiving 8-methoxypsoralen or psoralen at the 0·64-mgm. level had severe erythema of the ears, nose and face regions. These regions were sufficiently burned to be followed by scar formation, loss of hair, and thickening of the ears. The control animals (groups Nos. 1, 2, 13 and 21) showed less-severe ultra-violet burns. Groups receiving 0·01, 0·04, 0·16 mgm. of 8-methoxypsoralen or psoralen and the dietary groups showed no appreciable damage of irradiated regions. The groups receiving 0·64 mgm. in the pigmented mice showed less damage than the albino groups. During the first 45–100

Table 2. INCIDENCE OF EAR TUMOUR IN THREE STRAINS OF MICE EXPOSED TO ULTRA-VIOLET IRRADIATION AFTER ADMINISTRATION OF FUROCOUMARINS (PER CENT)

Strain	No drug		8-Methoxypsoralen (mgm./mouse/day)					Psoralen (mgm./mouse/day)				
	Controls		Oral administration (mgm.)				Dietary	Oral administration (mgm.)				Dietary
			0·01	0·04	0·16	0·64	1·7 mgm.	0·01	0·04	0·16	0·64	1·7 mgm.
Albino mice Swiss strain	60	70	50	45	40	45	65	55	65	40	60	60
Brown pigmented *C57Br/cd*	15		10	0		0	25	0			5	0
Black pigmented *C57BL/6*	20		5	5		10	15	0			15	5

Least wholly significant percentage point difference (5 per cent level) = 35 per cent; least wholly significant percentage point difference (1 per cent level) = 40 per cent.

Criterion for comparing any two cage outcomes: P_1-P_2 is significant at $P = 0{\cdot}05$ level if $P_1-P_2 \geqslant 1/2N + \frac{1{\cdot}96}{\sqrt{N}}\sqrt{P_1+P_2-1/2P_1^2-P_1P_2-1/2P_2^2}$, which reduces, when $N = 20$, to $0{\cdot}025 + 0{\cdot}451\sqrt{P_1+P_2-1/2P_1^2-P_1P_2-1/2P_2^2}$

days, the observers could not differentiate the control groups from the groups receiving 0·01, 0·04, 0·16 mgm. of drugs.. Cataracts developed in many of the animals, in both the control and dietary groups. The pigmented as well as the albino mice developed cataracts. Changes in the eyes were slightly more severe in all the groups on high doses (0·16–0·64 mgm.) of the two drugs. In the albino series, about 5–10 per cent of the mice had tumours of the eyelids. There were no tumours of the eyelid in pigmented groups. The death-rate up to the end of the irradiation period (120 days) was less than 10 per cent in all 28 groups.

The final tumour incidences are summarized in Table 2. In contrast to the findings of O'Neal and Griffin[13], there was no protecting or stimulating effect of 8-methoxypsoralen or psoralen on ultra-violet carcinogenesis in the albino mice. The incidence of tumours in the two pigmented strains of mice was much less than in the albino strain. Five of the groups showed no tumour, four groups had only 5 per cent tumours, two groups had 10 per cent; the rest of the five groups had tumour incidences ranging from 15 to 25 per cent.

The albino mice appeared to develop tumours earlier than the brown or black mice. After starting the ultra-violet irradiation, the control groups in the albino series showed first tumour induction at the end of 90 days; the control groups in both of the pigmented mice strains showed first tumour induction after 166 days. In the albino mice, eight out of the ten groups receiving psoralen or 8-methoxypsoralen, either orally or through the diet, developed tumours after 90–116 days. As compared to albino mice, the rate of tumour induction in both these pigmented mice strains receiving psoralen or 8-methoxypsoralen was very slow. In six pigmented groups, the first tumour induction time was around 147 days. In the rest of the other five groups which showed the development of tumours the induction time was greater than 166 days. The significant variable differentiating the albino and the pigmented strains appears to be melanin pigment. Presence of melanin pigment possibly retards tumour induction, and affords an appreciable protection against ultra-violet carcinogenesis.

There was no effect on the total tumour incidence of different dose-levels of the drug. There was neither potentiation nor protection from ultra-violet carcinogenesis. The albino mice groups receiving the highest dose of psoralen (0·64 mgm.), however, showed a shortened induction time, beginning at only 56 days. This acceleration of cancer induction is not surprising in view of the experimental damage to the animals on this high dose of 0·64 mgm. psoralen. It is of interest that the final tumour incidence did not increase in these animals. As mentioned previously, psoralen has been shown in experiments on humans to have a more potent photoactive effect than 8-methoxypsoralen[15]. This effect of psoralen in the present study was observed in only one albino group receiving the highest dose of 0·64 mgm. It accelerated the rate of tumour induction but not the total incidence. Psoralen and 8-methoxypsoralen otherwise showed similar responses and did not affect the final incidence of ultra-violet carcinogenesis in either albino or pigmented mice.

From these experiments it is concluded that the findings of O'Neal and Griffin[13] indicating that 8-methoxypsoralen provided protection against ultra-violet carcinogenesis are not confirmed. Under our conditions no potentiation of carcinogenesis was demonstrated by 8-methoxypsoralen or psoralen in dose-levels ranging from 0·01 to 0·16 mgm./mouse/day. Dietary feeding of psoralen or 8-methoxypsoralen (0·5 mgm./kgm. diet) did not reveal any protective effect against ultra-violet carcinogenesis. Some factor, possibly the melanin pigment in brown and black pigmented mice, appeared to protect the pigmented mice appreciably against ultra-violet carcinogenesis.

We are indebted to the Paul B. Elder Co., Bryan, Ohio, and Sandoz, Ltd., Basle, Switzerland, for the supply of the two compounds, and to Dr. W. L. Fowlks for his interest and guidance.

MUTAGENIC ACTIVITY OF THE ALKALOID HELIOTRINE IN *DROSOPHILA*

By Dr. A. M. CLARK
Department of Zoology, University of Melbourne

NATURALLY occurring chemical mutagens of plants are of considerable general interest because of the possibility that they make an appreciable contribution to the apparent spontaneous mutation-rate, both of the plants in which they occur and of any phytophagous animal species which may be sensitive towards them. In some cases, these mutagens might assume practical importance if they are active following ingestion by agricultural livestock. A number of the pyrollizidine alkaloids from various plants (*Heliotropium*, *Senecio*, *Crotalaria*) have been shown to possess considerable biological activity[1-3]. It therefore seemed worth while to test them for mutagenic properties. This article is intended to direct attention to the mutagenic activity of heliotrine, an alkaloid from *Heliotropium europaeum*[4].

To test the mutagenic activity of heliotrine in *D. melanogaster*, the Muller-5 technique for sex-linked recessive lethals was used. Following an injection of 0·08 µl. of a solution of heliotrine in 0·7 per cent sodium chloride, Canton-*S* males were mated individually to three *Basc* females, fresh females being provided at intervals of 72 hr. Cultures were maintained at 25° C. In the Canton-*S* stock in use in this laboratory, the spontaneous incidence of sex-linked recessive lethals is about 0·1 per cent for sperm produced during the first few days of adult life. All suspected lethals were confirmed in the F_3 and many have been kept in culture for further cytogenetic analysis.

Table 1. Production of Sex-linked Lethals following Injection into Adult Males of 0·08 µl. of a 0·3 per cent Solution of Heliotrine in Saline
Brood interval of 72 hr.

	Brood 1	2	3	4	5
Chromosomes tested	558	563	233	116	102
Lethals	31	10	17	6	3
Per cent lethals	5·6	1·8	7·3	5·2	2·9

The existence of perhaps two sensitive periods is suggested by the results in Table 1, representing the distribution of lethals over five successive broods following the injection in the males of 0·3 per cent heliotrine (approximately 0·01 *M*). The relatively small number of chromosomes tested from the last three broods is a reflexion of the partial sterilizing action of heliotrine in *Drosophila*. In fact, if the concentration of heliotrine exceeds about 0·5 per cent, the injection of 0·08 µl. of the solution renders it possible to obtain only the first two broods. The mutagen seems to block the maturation of immature germ cells, so that as soon as the available spermatozoa and spermatids have been utilized, the males are no longer capable of breeding, although they may remain alive and active for as long as three weeks after treatment. Since fertility is not regained within this period, the cell damage caused by the alkaloid is presumably quite irreversible.

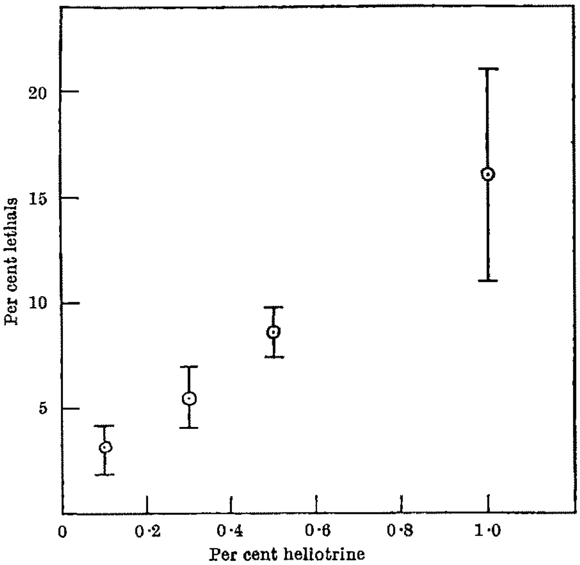

Fig. 1. Percentage of sex-linked recessive lethals (with 95 per cent confidence limits) at different heliotrine concentrations. First brood only

If the concentration of heliotrine is in excess of 1 per cent, then only a single brood is obtained, in which the incidence of lethals may be higher than 30 per cent. This single brood is often obtained as a result of copulation occurring within 1 hr. of treatment, indicating that the heliotrine does not in itself retard the mating behaviour of the males. Failure to obtain a second brood suggests some degree of destruction of spermatids or, alternatively, an inhibition of spermogenesis. By using alkaloid concentrations of less than 0·5 per cent several broods can be obtained readily, and the mutagenic effect is then found to extend back to pregonial cells. Clustering of lethals is common in these later broods.

Fig. 1 shows the results of an experiment to determine the relation of the dose response for the first brood only (spermatozoa mature at the time of treatment), using a ten-fold range in heliotrine concentration. Under the conditions of test, the relation appears to be linear. At the highest concentration used, however, the sampling error is large owing to the reduced number of offspring that can be obtained. Some deviation from simple linearity might be expected at the higher dose-levels in the light of observations (to be published elsewhere) on the ability of heliotrine to induce large structural rearrangements in *Drosophila*.

Bull, Dick, Keast and Edgar[3] have made an extensive investigation of heliotrope poisoning in sheep, and have shown that consumption of the plant results in severe liver damage. Bull[5] has further shown that heliotrine can produce similar damage to the liver of laboratory rats, while Schoental and Magee[3] have demonstrated the carcinogenic properties of the related alkaloid lasiocarpine.

Crowley and Culvenor[6] have found that different samples of *Heliotropium europaeum* may show considerable variability with respect to alkaloid content; but in none of their assays was there any indication that the content ever falls to a level at which hepatotoxic effects would not be expected to ensue following extensive feeding on the plant by sheep. However, even if the alkaloid-levels are low or if feeding is relatively restricted, there would now appear to be the possibility that livestock failing to develop toxic symptoms may nevertheless have suffered some degree of genetic deterioration.

The powerful mutagenic activity of heliotrine raises the interesting question of whether *Heliotropium* itself is sensitive towards this chemical. No information is yet available on this point. It may be recalled that although early work[7] seemed to suggest that *Colchicum autumnale* is resistant to the action of colchicine, later investigators have shown that this plant is in fact sensitive towards its own mitotic poison[8,9], and Takenaka[10,11] has reported disturbances of the *C*-mitotic type in root tips and pollen mother cells of *Colchicum* plants living under natural conditions. Nevertheless, it seems to be the case that rather high concentrations of the drug are necessary for typical colchicine effects to be produced. High-threshold concentrations may also characterize any mutagenic effects exerted by heliotrine upon the chromosomes of *Heliotropium*. It is, of course, possible that the mutagenic action is a property not of heliotrine itself but of some degradation product resulting from the enzymatic splitting of the alkaloid. In the intact plant, the enzyme may be lacking or it may be spatially separated by some means from the substrate.

A simple change which heliotrine might undergo after injection into *Drosophila* would be the splitting of the ester linkage, releasing heliotridine and heliotric acid. To test this possibility, hæmolymph and tissue homogenates were tested for esterase activity capable of splitting the alkaloid, but without success. In any event, heliotric acid is only feebly mutagenic when injected into *Drosophila*, while heliotridine is quite inactive, suggesting that the strong mutagenic property of heliotrine itself is probably a property of the molecule as a whole rather than of some degradation product.

My thanks are due to Prof. G. S. Christie of the Pathology Department of this University for first directing my attention to heliotrine as a possible mutagen, and to Dr. C. C. J. Culvenor of the Commonwealth Scientific and Industrial Research Organization, Division of Industrial Chemistry, for providing samples of various pyrollizidine alkaloids.

COSMIC DUST IN THE ATMOSPHERE

By DR. D. W. PARKIN and W. HUNTER

Department of Physics and Mathematics, Liverpool College of Technology

THE extensive work of Prof. H. Pettersson and his colleagues[1] and the analytical work of Smales *et al.*[2] have established that certain magnetic spherules (about 50μ diameter) obtained from deep-sea sediments are extra-terrestrial. Magnetic spherules, similar in size and appearance to these 'cosmic spherules', have been collected by several observers directly from the air. Buddhue[3] showed that many such spherules could be picked up, daily, by a greased slide. However, vast numbers of these particles appear in chimney fly-ash and some doubt exists concerning the origin of spherules collected, even in isolated places.

During August 1957, a plastic bowl of filtered water, area 1/6 sq. m., was exposed at the top of the lighthouse on Bardsey Island (North Wales), in the hope of detecting fine dust from the Perseid meteor shower. About fifty black or silvery magnetic balls of around 10μ diameter were collected daily. This number varied according to weather conditions, strong winds and no rain increasing the daily catch considerably. Towards the end of this examination, attention was attracted to certain metallic-looking flakes ; and it was established that some of these were metallic iron, copper being immediately deposited from a surrounding bead of copper sulphate solution. X-ray examination of one of these particles showed it to be fine-grained polycrystalline iron.

About a gallon of melt-water, obtained by Mr. L. K. Coachman (Department of Oceanography, University of Washington) from the wall of a crevasse in West Greenland, yielded 19 magnetic spherules ranging in diameter from 5μ to 35μ (mainly about 20μ in diameter). In addition to many black and vari-coloured magnetic fragments, four flakes of metallic iron similar to the Bardsey specimens were found. One of these was a remarkably straight needle-shaped object of square-like cross-section 240μ long and 20μ wide.

On occasions during the summer months, aircraft of the Meteorological Research Flight have been collecting samples of dust over southern England at 10,000 ft., while flying at a speed of about 200 m.p.h. A slotted 'Perspex' slide of effective collecting area 10 sq. cm. was thinly coated with gelatine. Each slide, held in an aluminium frame, was exposed from the side of the fuselage, for exactly 30 min. The results of flights carried out on August 11 and 20, 1958, are of particular interest. Three slides were exposed during each flight.

'Terrestrial-looking' sand particles (generally flakes) as large as 150μ were found, but the presence of only a few spherules was surprising. On average, each slide picked up two or three sand grains of about 100μ diameter, a dozen around 50μ and many more in the smaller size-ranges. Only one or two opaque spherules (10μ–20μ) were observed. Among the fragmentary opaque material, which followed a similar size-distribution, several interesting metallic-bearing particles were found.

On a slide exposed during August 20, a large silvery flake ($200\mu \times 100\mu \times 20\mu$) was found firmly embedded in the gelatine layer. In parts it was covered with small grey translucent balls which appeared to sprout from the surface, and the particle appeared to be a loosely aggregated structure of small grains. The addition of copper sulphate quickly turned it a matt black-bronze, with here and there bright specks of copper. By softening the gelatine it was possible to lever out a large section, and Fig. 1 shows the impact region on the gelatine, together with a few pieces that remained in position (The tiny specks around the main area are chippings made by a glass fibre.) The extracted section was to be examined by X-rays, but during manipulation in a pool of glue it fell apart. On the same slide another flake, about 50μ in size, embedded like a knife blade in the gelatine, reacted immediately to the copper sulphate test.

The long needle-shaped particle (Fig. 2) is typical of another kind of fragment. This at first did not react to copper sulphate, but later dendritic copper grew out from certain spots which are presumably the sites of cracks in a surface oxide layer. Although most attention was paid to the large fragments, several of the smaller ones deposited copper, particularly after their surfaces had been damaged.

These oxide-coated particles must be similar to those described by Buddhue, who noticed that some of the fragments emitted tiny bubbles when the sample was under acid. He also detected chemically the presence of more iron after the sample had been crushed.

The possible extra-terrestrial nature of these metallic fragments must be seriously considered. On the average, each slide collected about one as large as 100μ, and since sand grains of this size-range occurred with only two or three times this frequency, it seems unlikely that the metallic particles could have been transported from ground-level to 10,000 ft. Industrial dust, collected over Liverpool, has been examined on many occasions, and although metallic iron fragments have been found they are located with the utmost difficulty. These fragments must be abraded from common iron as they are observed to rust quite readily.

The water-bowl technique was again adopted during August 1958. The bowl, of area 1/15 sq. m., was placed on a rocky prominence at the south-west tip of St. Agnes, Isles of Scilly. The winds were mainly in the south-west and since scarcely a day was free from rain the air was particularly clean. A thorough examination of the magnetic fraction in the water samples has now been completed, the non-magnetic portion being preserved for later inspection.

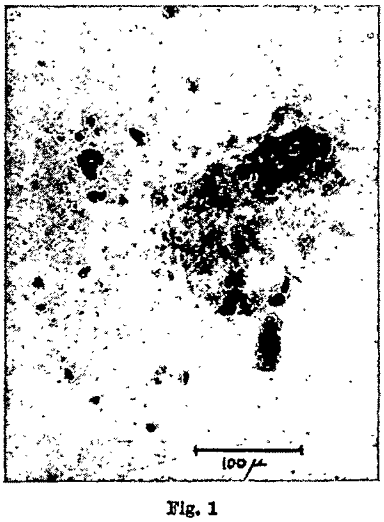

Fig. 1

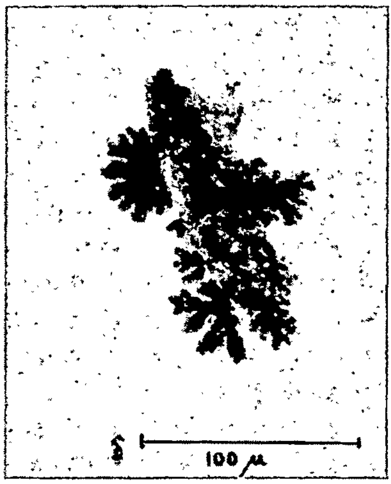

Fig. 2

On average, during a 48-hr. exposure, about a dozen black powdery aggregates varying in size around 40μ were recorded, together with two or three silvery flakes of the same size. For the whole month only 15 spherules about 10μ in diameter were collected; and only three silver flakes and one black flake were found to react to the copper sulphate test either immediately or after slight crushing. But a large (150μ) partly translucent aggregate picked up during the period August 11–13 was observed to deposit copper in a few spots on the surface and between the crystalline (or glassy) material, which appeared to be quite angular and slightly brown in colour. The presence of transparent material could be detected in the other metallic fragments particularly after they had been crushed.

Perhaps the strongest argument in favour of an extra-terrestrial origin is the detection of nickel in these particles. Due to a chemical method devised by Dr. J. P. Riley (Department of Oceanography, University of Liverpool), it has been possible to show a slight trace of nickel in the remnant in Fig. 1, and to be quite certain of its presence in the metal-bearing Scilly particles, using them all together.

The quantity of nickel is unknown, but from experience gained with particles of nickel-steel of given composition, it is fairly certain that in the Scilly particles the average nickel content is greater than 5 per cent.

Owing to the small quantity of material collected, it is impossible to be certain of a contribution from the Perseid shower. As emphasized by Öpik[4], it is likely that the large, and possibly continuous, fine dust deposit from the Zodiacal Cloud completely overwhelms any contribution from a meteor shower. Nevertheless, it is important to clarify this question, as Bowen[5] has given evidence of possible initiation of rainfall by meteor showers. If this extra-terrestrial material turns out to be primordial dust, a closer study of the metallic and stony material will be of great interest, as the particles should reflect conditions existing during their formation. Sampling the stratosphere would put much of this work on a surer footing.

We are indebted to Prof. K. F. Bowden of the Department of Oceanography, to Prof. W. S. Owen of the Department of Metallurgy, University of Liverpool, and to the Director General of the Meteorological Office, for facilities, and to Sir Edward Bullard of Cambridge, and Mr. B. C. Oddie of the Meteorological Office for much encouragement. We are especially grateful to Mr. W. G. Durbin, of the Meteorological Research Flight, for his participation in the experiment, and our thanks are due to several colleagues in the College of Technology, Liverpool.

RESOLUTION OF CHLORPHENIRAMINE AND THE PHARMACOLOGICAL PROPERTIES OF ITS ISOMERS

By R. T. BRITTAIN, DR P. F. D'ARCY and DR. J. H. HUNT
Research Division, Allen and Hanburys, Ltd., Ware, Herts

CHLORPHENIRAMINE maleate ('Piriton', Allen and Hanburys, Ltd.) [3-(*p*-chlorophenyl)-3-(2'-pyridyl)-NN-dimethyl propylamine maleate][1,2] is a potent antihistamine[3]. We wish to report its resolution, and the physical constants, and the pharmacological properties of its optical isomers.

Chlorpheniramine proved somewhat difficult to resolve since it forms readily crystallizable salts with only a few acids. Initial attempts to form crystalline salts from fifteen optically active acids were not successful; however, after standing for one year, a solution of the di-*p*-toluoyl-(−)-tartrate[4,5] in aqueous ethanol deposited a few crystals. These were used to seed a freshly prepared solution giving (−)-chlorpheniramine-di-*p*-toluoyl-(−)-tartrate, which, after recrystallization to constant rotation, had melting point 135–136° C., $[\alpha]_D^{21} + 57\cdot4°$ (*c.* 1·1 in ethanol). This gave (−)-chlorpheniramine [$[\alpha]_D^{21\cdot5} - 31\cdot6°$ (*c.* 1·8 in ethanol)], which was converted to the hydrogen maleate [melting point 114–115° C., $[\alpha]_D^{27} - 23\cdot7°$ (*c.* 1·2 in water)].

The corresponding antipodes were obtained from the di-*p*-toluoyl-(+)-tartrate [melting point 135–36°, $[\alpha]_D^{20} - 57\cdot8°$ (*c.* 1·7 in ethanol)], which gave (+)-chlorpheniramine [$[\alpha]_D^{24} + 31\cdot6°$ (*c.* 1·3 in ethanol)], which was converted to the hydrogen maleate [melting point 114° C., $[\alpha]_D^{20} + 23\cdot1°$ (*c.* 2·0 in water)].

The anti-histamine activity of each isomer and the racemate was assessed by an *in vitro* method. The antagonistic effect of each drug on the contractions induced by histamine of the isolated ileum of the guinea pig was determined following the method of Schild[6]. The results expressed as pA_2 values (2 min. drug-tissue contact) are shown in Table 1.

The (+) isomer exhibited approximately twice the anti-histamine activity of the racemate, while the (−) isomer showed only about half the activity of the racemate. Further studies in which the pA_2 values of the drugs were assessed after 4 and 8 min. contact with the tissue showed that the duration of the anti-histamine action of neither isomer differed from that of the racemate.

Table 1

Compound	Anti-histamine activity pA_2 value (2 min. drug–tissue contact)
(+)-Chlorpheniramine maleate	8·47
(±)-Chlorpheniramine maleate	8·10
(−)-Chlorpheniramine maleate	7·81

Table 2

Compound	Acute intraperitoneal toxicity in mice $LD50$ mgm./kgm. ± standard error
(+)-Chlorpheniramine maleate	175·4 ± 9·7
(±)-Chlorpheniramine maleate	187·9 ± 6·7
(−)-Chlorpheniramine maleate	193·6 ± 7·5

The acute intraperitoneal toxicity of the racemate and isomers was studied in mice. Low doses of both racemate and isomers showed no observable reactions; however, high doses produced clonic convulsions followed by depression and death. Mortality was observed for seven days after administration of the drug. These results, expressed as the *LD*50 value in mgm./kgm. for each anti-histamine, are shown in Table 2. It is apparent that the acute toxicity of each isomer does not differ significantly from that of the other, nor from that of the racemate.

Sedation is one of the more common side-effects of many of the anti-histamine drugs in clinical use; it was therefore thought worth while to determine whether the racemate or either isomer caused any depression of the central nervous system. This was achieved by examining the compounds for their effect in modifying the narcotic activity of intraperitoneal injections of pentobarbitone sodium in mice. Narcotic activity was estimated using the rotating drum method of Collier, Hall and Fieller[7]. These results are summarized in Table 3, and show that neither of the isomers nor the racemate potentiates the action of the barbiturate. In fact, all three compounds, when injected intraperitoneally at a dosage of 100 mgm./kgm. at the same time as the pentobarbitone sodium, significantly reduce the duration of the narcosis without affecting the onset.

It has been well established that many antihistamines have a local anæsthetic action, a property that contributes to the beneficial effects of topical application of these agents in painful allergic or other dermatological conditions. In this study the local anæsthetic activity of the isomers and the racemate were determined in guinea pigs using the intradermal injection method of Somers and Edge[8]. Racemic chlorpheniramine maleate showed similar local anæsthetic activity to that of procaine hydro-

Table 3

Compound	No. of mice	Dose (mgm./kgm. intra-peritoneally)	Narcosis in mice				
			Pentobarb. sod. (mgm./kgm. intraperitoneally)	Onset (min. ± stand. error)	P	Duration (min. ± stand. error)	P
Saline	10	—	30	$3\cdot7 \pm 0\cdot5$	—	$16\cdot1 \pm 0\cdot9$	—
(+)-Chlorpheniramine maleate	10	100	30	$3\cdot7 \pm 0\cdot6$	$> 0\cdot9$	$12\cdot8 \pm 1\cdot0$	$< 0\cdot05$
(±)-Chlorpheniramine maleate	10	100	30	$4\cdot8 \pm 1\cdot0$	$> 0\cdot3$	$11\cdot6 \pm 1\cdot3$	$< 0\cdot01$
(−)-Chlorpheniramine maleate	10	100	30	$3\cdot8 \pm 0\cdot7$	$> 0\cdot8$	$11\cdot3 \pm 1\cdot6$	$< 0\cdot02$

chloride. The activity of the (−) isomer was approximately one and a half times, while the (+) isomer was only half that of the racemate.

It has been reported[9] that continued local use of anti-histamines may cause skin sensitization reactions. In view of the combination of potent anti-histaminic and local anæsthetic activity of chlorpheniramine maleate and its isomers, and their possible use in topical application, it was considered important to determine whether these compounds produced skin sensitivity. Formulated preparations of the racemate and the two isomers were therefore examined for their possible irritant action upon shaved rabbit skin. Each preparation contained 2 per cent of anti-histamine and was applied twice daily for two weeks. There was no evidence of any degree of skin sensitization during this time with any of the preparations. After treatment had stopped, the rabbits were exposed to sunlight and daylight for a further two weeks; at the end of this time there was no evidence of any photosensitivity reaction in the treated areas of skin.

The experiments performed indicate that the pharmacological activities of both the (+) and the (−) isomers of chlorpheniramine maleate are qualitatively similar to those of the racemate. The (+) isomer is more active than the racemate as an anti-histaminic drug, but is less active as a local anæsthetic; the reverse is true with the (−) isomer. In view of this quantitative difference in activity, it is interesting to note that the acute intraperitoneal toxicities of the compounds in mice are similar. It is proposed to compare the possible anti-tussive action of each of these isomers with that of the racemate.

While this communication was being written, the results of some pharmacological investigations on the optical isomers of chlorpheniramine were reported by Roth and Govier[10], but no details of the resolution or physical constants of the isomers were given. Anti-histamine and central nervous system activity and toxicity were investigated; our results are in agreement with theirs with the exception of the anti-histaminic activity of the (−) isomer, which was reported to be only 0·01 of that of the racemate.

We thank the directors of Allen and Hanbury's, Ltd., for permission to publish this work, and Mrs. P. Hutchings, Mrs. G. Hayes, Miss R. Wilkins and Mr. R. Hornby for their technical assistance.

MORPHOGENETIC RESPONSE OF *CITRUS* OVULES TO GROWTH ADJUVANTS IN CULTURE

By N. S. RANGA SWAMY

Department of Botany, University of Delhi

OUR understanding of the growth processes of ovules and their individual parts, namely, the integuments, nucellus, endosperm and embryo from inception to the adult stage, is incomplete. A study of the growth and differentiation of 'entire' ovules (pre- and post-pollination stages) using tissue-culture technique as a tool is of great use in unravelling the physiological and morphological changes that occur within them following pollination and fertilization. Apart from a few cursory reports, ovule culture is yet an unexplored field. White[1] and LaRue[2] secured a callus growth on the ovules of *Antirrhinum* sown in White's medium. The ovules of *Erythronium americanum* showed a four-fold increase in size and an irregular growth of their surface. With orchids, Withner[3] found ovule culture to be quite promising for shortening the period elapsing between pollination and maturation of the seed, and for hastening the production of seedlings. Recently, Nirmala Maheshwari[4] has reported that poppy ovules cultured at the 2-celled stage of the embryo on Nitsch's basic medium containing a mixture of vitamins, glycine, kinetin (0·4 p.p.m.) and indoleacetic acid (5 p.p.m.) grew to mature seeds capable of germination *in situ*.

From relevant literature, it would appear that no culture work has so far been done on ovules possessing adventive embryos. The present investigation was undertaken with the view of exploring the nature of response of ovules that are naturally polyembryonate to such growth supplements as coconut milk, tomato juice and malt extract.

Citrus microcarpa Bunge was chosen as the ovule source. The young fruits were surface-sterilized and the ovules dissected out. Ovules, in which nucellar embryos had been just initiated, were inoculated on White's medium which was used as control[5]. 3 and 5 per cent sucrose were also tried as carbon source and the growth adjuvants used were Seitz-filtered.

Fig. 1. *A*, two-week-old culture of ovule on White's medium + coconut milk (40 per cent). Note the hypertrophy (× *c*. 0·3); *B*, same as *A*, on White's medium + malt extract (0·5 per cent) + sucrose (3 per cent). Observe the extensive growth of fragile tissue (× *c*. 0·3)

Fig. 2. L.S. ovule from Fig. 1*B* (× *c*. 5)

Fig. 3. L.S. chalazal portion of two-week-old ovule on White's medium + sucrose (5 per cent). Note the periderm formation (× *c*. 6)

Fig. 4. L.S. micropylar part of two-week-old ovule on White's medium + sucrose (5 per cent). Note the cellular endosperm along the periphery and embryos of different stages (× *c*. 4)

Fig. 5. L.S. embryo from two-week-old ovule on White's medium + tomato juice (20 per cent), showing proliferation from basal portion (× *c*. 30)

emb, embryo; *end*, endosperm; *hyp*, hypostase; *ii*, inner integument; *nu*, nucellus; *oi*, outer integument; *p*, periderm

In all the concentrations of sucrose, the ovules swelled and showed hypertrophy of the integument accompanied by surface undulations. Later, the integument ruptured at certain places, exposing masses of glistening white tissue. The proliferations were abundant over the entire surface of the ovule except the micropylar region. In this respect 5 per cent sucrose proved superior to other concentrations.

The control medium supplemented with coconut milk (40 per cent) gave a similar response, though it was less pronounced (Fig. 1*A*). With tomato juice (20 per cent) but without indoleacetic acid and vitamins, no appreciable change in hypertrophy was noticed when compared to the control. Proliferations were, however, extensive on White's medium + 0·5 per cent malt extract (Figs. 1*B*, 2). The entire surface of the ovule showed intumescences which were of a more or less friable nature. Subcultures of such detached tissue masses did not prove successful.

Microtome sections of treated ovules revealed the following features.

The outer integument was potentially proliferative. Although no mitoses were observed, the arrangement and differentiation of the cells in a regular fashion indicated that the new tissue arose by cell divisions rather than by mere cell enlargement. The intumescent tissue originated mainly from the cambium-like cells of the sub-epidermal layers of the integument. The tissue showed 2–3 layers of tangentially elongated cells containing dense cytoplasm and a prominent nucleus. Outside these were cells which had a more vacuolate cytoplasm and degenerating nucleus; and the outermost 2–3 layers of cells were suberized. The whole structure simulated a periderm tissue (Fig. 3). In some cases isolated tracheidal cells were also found in the proliferated tissue. The inner integument did not show any response to the various treatments.

No appreciable growth of embryos was noticed in ovules cultured on White's medium containing 2 or 3 per cent sucrose. But in those on 5 per cent sucrose, the proembryos enlarged in size by cell divisions and differentiation occurred in 2 weeks (Fig. 4). However, a considerable variation in their development was met with and different stages could be seen in the same ovule. On White's medium plus tomato juice a similar response was obtained. Some embryos showed proliferations from the basal region (Fig. 5). No differentiation of embryos could be achieved either on coconut milk or malt extract.

The endosperm tissue was generally inhibited and was attenuated during development, but in ovules grown on White's medium containing varying concentrations of sucrose its growth was normal, and 2–3 layers of endosperm could be observed bordering the embryo sac. The nucellar tissue was unaffected by growth modifiers except that the cells were much elongated along the axis of the ovule.

Briefly, then, the ovules of *Citrus microcarpa* cultured on different media became hypertrophied and irregular in outline, especially so on malt extract, perhaps due to osmotic gradients in the medium. A periderm-like tissue was formed from the outer integument in almost all the treatments. It is interesting to note that proembryos when excised and cultured on White's medium showed no growth[5], whereas in cultures of whole ovules the growth and differentiation of the embryos proceeded normally. The artificial induction of budding of proembryos obtained by exogenous application of growth factors, such as tomato juice, is significant as a source of securing identical progeny.

I am grateful to Prof. P. Maheshwari and Dr. S. Narayanaswami for guidance, encouragement and helpful suggestions. Thanks are due to the Council of Scientific and Industrial Research, New Delhi, for financing a scheme of research on *in vitro* culture of plant organs under which this work was carried out.

LETTERS TO THE EDITORS

PHYSICAL SCIENCES

Origin of the Lunar Craters and Maria

I am prompted to tender a few pertinent comments on the recent communication by Prof. Zdenĕk Kopal[1].

The physiographical similarity between many of the lunar craters and those produced by man-made explosions has been pointed out by Baldwin[2], and, if one dare assume that at least some of the lunar craters were produced by impacting objects, one can make use of this similarity and the present state of knowledge on the strong shock hydrodynamics of explosive cratering in estimating the relative energies involved and—with a slightly greater uncertainty—the masses which produced them. My own analysis, which I hope to publish shortly, leads me to believe that Baldwin's energy figures should be revised sharply upwards, that is, that the kinetic energy of an impacting mass would have to be of the order of 10^{28} ergs to produce a crater twenty miles in diameter, and one expects the diameter to vary as the cube-root of the impacting energy. While the energy partition in a venting underground explosion depends critically on the depth of penetration, present experience indicates that as much as one-half the incident energy may be absorbed in ground shock for deeply penetrating explosions. Most of this energy is absorbed in irreversible heating of the rock in a very short distance, and when the shock pressures have degraded to the order of the elastic strength of rocks (about 1 kilobar), the energy available for propagation as seismic waves is not likely to be more than 1 per cent of the incident energy.

Thus we are back again to a figure like 10^{26} ergs of seismic energy emanating from an impact capable of producing a crater 20 miles in diameter. I believe also that it is not unfair to seismologists to state that there is a disagreement of at least three orders of magnitude in the total seismic energy from the largest terrestrial earthquakes, with 10^{25} ergs as the lowest estimate. Thus it is not unreasonable to presume that the formation of a crater as large as Alphonsus would be accompanied by a moonquake of comparable intensity to the largest earthquakes, and the presence of craters twice as large as Alphonsus implies an increase of one order of magnitude in the seismic energy. In contradistinction to earthquakes, the seismic energy from an explosion is preferentially concentrated in the P-phase, with very little going into S-phase (Rayleigh waves), and the region undergoing substantial Earth motion is confined to within one or two crater radii. It appears extremely doubtful that even the largest craters, if attributable to impact, would exhibit widespread damage visible from the Earth.

With regard to conditions at the anti-focus, even if one disregards the difference in arrival times (of Rayleigh waves exclusively) due to anisotropy and non-sphericity of the lunar globe, and admits an energy concentration an order of magnitude below that at the source, there is little reason to expect any pronounced physical disturbance at the assumed caustic. The early processes in the production of seismic energy at the source are irreversible; certainly no crater would be formed. A more likely situation would be the local enhancement of ground motion, but probably never exceeding the elastic limit of the rock.

Prof. Kopal postulates that an impacting cometary mass possessing 10^{31} ergs of kinetic energy could produce 10^{20} gm. of molten lava. The results of the 'Ranier' underground atomic test in Nevada[3] indicate that less than 0·1 per cent of the total mass of material within the fracture zone was fused, and that cooling of the entire volume to temperatures like 100° C. took place in less than 1 hr. Although the equivalent of one-half the thermal energy of the bomb was required to fuse this mass of material, resolidification (if it was ever melted at all) occurred almost immediately, and the fused material was brecciated and intermingled with other debris when the cavity collapsed. In the case of a surface, or near surface, explosion, one would expect that the fused material would be thrown out of the crater along with the other debris, and not collected as a molten pool in the bottom of the crater. The distribution of fused material around the Canyon Diablo crater already supports this hypothesis.

[1] Kopal, Z., *Nature*, **183**, 169 (1959).

[2] Baldwin, R. B., "The Face of the Moon" (Chicago Univ. Press, 1949).

[3] Preliminary Report of Operation Plumbob, University of California Radiation Laboratory, Report 5124).

If Dr. van Dorn is right in concluding that the energies of meteor impacts necessary to produce lunar craters of given size are actually about 100 times larger than those postulated by Baldwin, the seismic arguments put forward in my letter of January 17 would be correspondingly strengthened; for the available estimates of the largest energies of terrestrial earthquakes range between 10^{23} and 10^{27} ergs, with 10^{25} ergs as a fair average (Gutenberg, 1958).

The fact that seismic energies of terrestrial surface explosions are spent preferentially in the P-waves is of no direct lunar relevance; for, first, the epicentres of lunar meteor explosions should be at least a few thousand yards deep (that is, far from pure surface phenomena in the terrestrial sense); and, secondly, the much lower gravity would allow S-waves on the Moon to attain greater amplitudes than on the Earth. Moreover, the real point of my communication was to direct attention, not to the damage caused by seismic waves in the immediate neighbourhood of an impact, but rather to the cumulative effects which hundreds of thousands of such occurrences would be bound to entail, and which have not been paid any attention in all previous work.

The focusing (however imperfect) of lunar S-waves in the anti-focal region should produce increased fragmentation and destruction, rather than any new crater. Whether or not the elastic limit of rock could be attained remains wholly conjectural.

Lunar comet impacts and terrestrial nuclear explosions differ by so many orders of magnitude in mass, energy, as well as temperature (quite apart from different gravity and absence of atmosphere around the Moon) that scarcely any valid conclusions can be drawn from their comparison. On the other hand, to postulate the occurrence of hundreds of thousands of major meteor impacts on the Moon without simultaneous consideration of the collisions with comets would be so grossly at variance with the present frequencies of both types of bodies as to make little or no astronomical sense. As the meteor impacts on the Earth or the Moon must be accepted as facts, and their effects traced, the same must be true of the comets ; and if lunar maria are not the results of such encounters, what else have comets done to the Moon?

Low-Energy Corpuscular Radiation at High Latitudes

IN high latitudes, at altitudes of order 100 km., a flux of electrons (50–90 keV.) dependent on latitude has been detected[1]. Protons of energy up to at least 90 keV. appear in auroræ[2]. I propose an explanation of this observed high-latitude corpuscular radiation on the basis of an acceleration mechanism discussed by Bohm and Gross[3].

This mechanism involves travelling (electron) electrostatic waves satisfying the dispersion relation :

$$V^2 = \frac{w^2}{K^2} = \frac{4\pi n e^2}{mK^2} + \frac{3kT}{m}$$

where V = phase velocity of the wave ; w = angular frequency of the wave ; K = wave number of the wave ; n = electron density ; e,m = charge, mass of electron ; k = Boltzmann's constant ; and T = temperature of region. Charged particles can be trapped[4] between the potential crests of such a wave and carried with velocity V, which increases as the wave is propagated into regions of increasing electron density.

Bohm and Gross[4] showed that electrostatic waves are infinitely damped as their wave-number approaches the lower limit $2\pi(kT/\pi^2 ne^2)^{1/2}$. Hence, their band of allowable frequencies is given by :

$$\frac{4\pi n e^2}{m} \leqslant w^2 \leqslant \frac{4\pi n e^2}{m}\left(1 + \frac{3\pi}{4}\right)$$

From this it is seen that the maximum possible penetration of an electrostatic wave generated in a region of electron density n is to one of electron density $\left(1 + \frac{3\pi}{4}\right) n$.

I suggest that electrostatic waves are generated in the exosphere by solar corpuscular streams. The waves are propagated along the geomagnetic field lines, trapping charged particles and accelerating them down to levels where the electron density has increased by at most a factor $\left(1 + \frac{3\pi}{4}\right)$. At these levels the energy of the waves will have been fully converted to kinetic energy of particles moving down along the geomagnetic field lines.

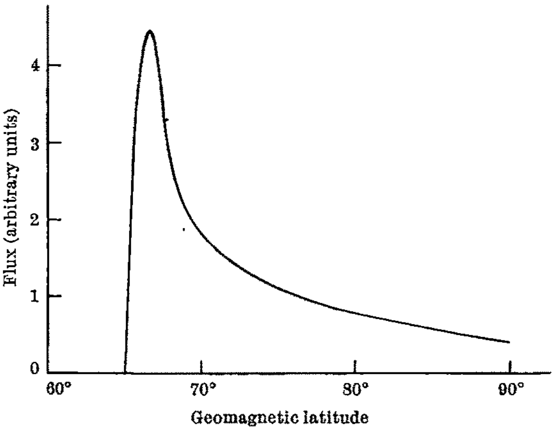

Fig. 1. Calculated variation with geomagnetic latitude of the flux of low-energy corpuscular radiation at the Earth

For purposes of calculation it is assumed that the electrostatic waves are generated at a spherical surface of radius 6·5 Earth radii and the trapping and accelerating region to be a spherical shell one Earth radius thick. Further, the flux of accelerated particles is assumed to be proportional to the volume of their trapping and accelerating region.

The calculated variation of accelerated particle flux with geomagnetic latitude is then of the form illustrated in Fig. 1. This closely fits the observations of Van Allen[1] for electron flux and resembles the latitude distribution of auroræ[5].

An estimate follows of an upper limit of the mean absolute flux, F, of accelerated protons (or electrons) at the Earth's surface. It is assumed that the energy of solar particles captured by the exosphere is fully converted to energy of electrostatic waves and then to energy of trapped particles. Hence, ignoring the kinetic energy carried by electrons :

$$sV_0\pi\alpha^2 \times \tfrac{1}{2}mV_0{}^2 = F \times f \times 4\pi a^2 \times \tfrac{1}{2}mV_1{}^2$$

where s = number density of protons (or electrons) in the solar particle stream, V_0 = velocity of solar particles, α = radius of spherical surface at which electrostatic waves are generated, m = proton mass, f = fraction of Earth's surface on which accelerated particles are precipitated, a = radius of Earth, V_1 = velocity of accelerated particles.

Taking s = 10 cm.$^{-3}$, $V_0 = 10^8$ cm. sec.$^{-1}$, $V_1 = 10^9$ cm. sec.$^{-1}$, $\alpha = 6\cdot5\, a$, $f = 0\cdot1$ (polar regions) leads to $F \approx 10^9$ cm.$^{-2}$ sec.$^{-1}$. This might be compared with the value 6×10^7 cm.$^{-2}$ sec.$^{-1}$ inferred by Chamberlain[6] for the flux of protons in auroræ and the value $10^6 - 10^8$ cm.$^{-2}$ sec.$^{-1}$ from Van Allen[1] for the flux of electrons.

From the above dispersion equation it is seen that this discussion is untenable unless $T \leqslant \frac{mV_0{}^2}{3k}$ in the particle-trapping region. For $V_0 = 10^8$ cm. sec.$^{-1}$ then we must have $T < 20{,}000°$ K.

Gravity Survey on the Kuttyaro Caldera by means of a Worden Gravimeter

LAKE KUTTYARO, in the eastern part of Hokkaido, Japan, is the western half of a circular caldera, which is one of the largest in the world, being about 20 km. in diameter. A small island at the centre of the lake and parasitic volcanoes in the other half of the caldera are supposed to have erupted after its formation.

At present, gravity measurement on the water is very difficult. Fortunately, we were able to use a Worden gravimeter on the surface of Lake Kuttyaro because it freezes hard in winter. It is noteworthy that the free air reduction and the Bouguer correction are uniform over the lake, and the topographical correction is very small in this region. A survey on the ice was carried out in March 1958. The Bouguer anomalies obtained on and near the lake (Fig. 1) display a relatively low anomaly of about 46 milligals, concentrated at the centre of the caldera. Comparing the distribution of the Bouguer anomalies with that of the depth of the lake (Fig. 2), it is clear that the Bouguer anomalies are almost independent of the minor structures of the surface of the ground and the depth of the lake, and must be related to the subterranean structure on a larger scale. Analysis of the distribution of the Bouguer anomalies shows that coarse material with a density about 0·3–0·5 gm./cm.^{3} smaller than that of its surroundings has accumulated at a depth of 3–4 km. beneath the lake. This coarse material is supposed to be pumice ejected during the formation of the caldera, such as is actually found widely spread over the surface of the ground in the neighbourhood. The distribution of the Bouguer anomalies gives the total mass-defect which is responsible for the low anomaly as 10^{11} tons. This value coincides with an estimate by Y. Katsui (Geological Institute, Hokkaido University), who has studied the distribution of the ejected pumice. The mechanisms by which enormous amounts of pumice were ejected and the caldera was formed cannot be elucidated by gravity survey alone, but the eruption, accompanied by the accumulation of pumice, must clearly have been so violent that the region from the surface to a depth of 3–4 km. was completely devastated.

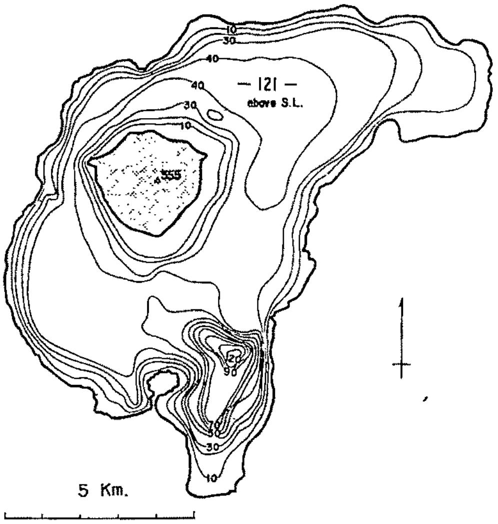

Fig. 2. Depth contours in Lake Kuttyaro (in metres)

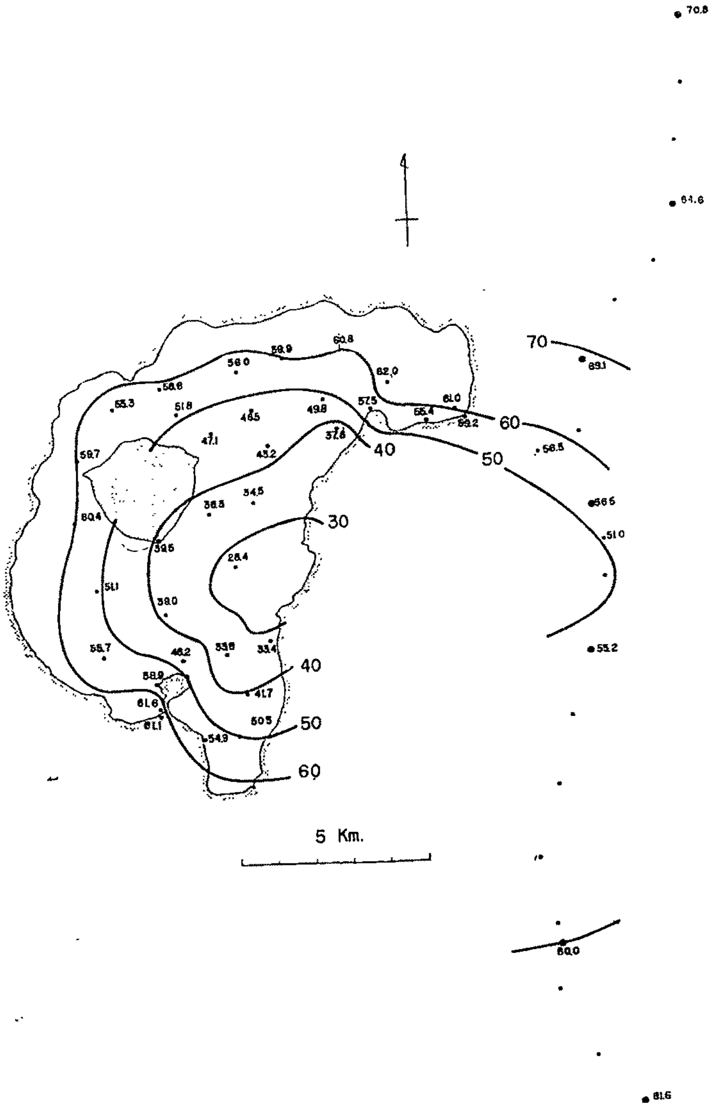

ig. 1. Distribution of the Bouguer anomaly (in milligals)

From a petrological discussion of the pre- and post-caldera lavas, H. Kuno[1] classifies the Japanese calderas as belonging to the Krakatoa or the Glencoe types of H. Williams[2], according to the cause of their formation. An example of the former type is the Kuttyaro caldera, which collapsed into the magma reservoir accompanying the eruption of a tremendous amount of pumice; and one of the latter type is the Mihara caldera, Oosima Volcano, which was formed by the subsidence of a great mass of rocks into the magma reservoir, without the eruption of pumice. We fear that the term 'magma reservoir' in this account lacks confirmation. From this geological point of view we should expect to observe low Bouguer anomalies on calderas of the Krakatoa type and high Bouguer anomalies on calderas of the Glencoe type. Actually, the result of a gravity survey carried out on the Volcano Mihara[3] shows a high anomaly, amounting to about 15 milligals. This fact, and the low Bouguer anomaly observed on the Kuttyaro caldera, seem to justify the proposed geological classification based on the formation of the calderas, but the mechanism of subsidence or collapse is another problem which we regard as unsolved.

A full account of gravity surveys on several volcanoes in Japan will be published elsewhere.

This work is being continued while one of us (I. Y.) is studying at the Istituto di Fisica Terrestre, Università di Napoli.

Measurement of the Flocculation of Suspensions

I HAVE read with interest the communication by R. L. Whitmore in *Nature* of January 31, p. 313, on the devolopment of a test which was introduced by Prof. Fahraeus in 1958.

We have been using this method for testing 'Oildag' (colloidal graphite in oil, Acheson Industries (Europe), Ltd.) dispersions since 1939, and have, in fact, developed a special apparatus which allows a roll of Whatman No. 4 filter paper to be folded into a pack of 25 or more papers. The 'Oildag' concentrate is diluted with *SBP*.3 fluid, poured into the reservoir and allowed to flow through under gravity. A typical 'chromatogram' obtained by this method is shown in Fig. 1.

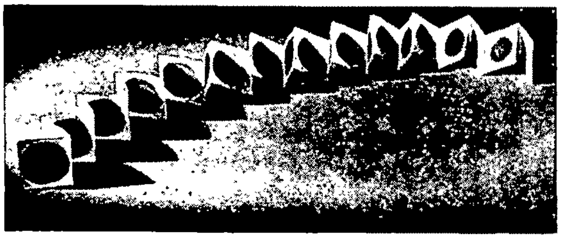

Fig. 1

I might add that we have supplied this test rig to people in many countries, as we found it a very easy method of distinguishing quickly between 'Oildag' and less stable dispersions of graphite in oil.

β-Type Interlamellar Sorption Complexes

IN what we have called[1] the 'β-type' interlamellar sorption complexes of graphitic acid, the sorbed molecules are probably standing normally to the layers of the sorbate. The β-complexes with normal straight-chain amines, which we have been investigating, are particularly interesting, since they are formed over a complete range of chain-lengths.

Our new results are plotted in Fig. 1. Between 4 and 16 carbon atoms, the spacing rises linearly with the chain-length, and the slope of the line is 2·6 A. per carbon atom. This corresponds almost exactly to the projected length of two C—C single bonds, and indicates that there are two layers of sorbed molecules oriented normally to the sorbate layers. Fig. 1 shows a slight shift at 10 carbon atoms. We will not enlarge here on possible reasons for this.

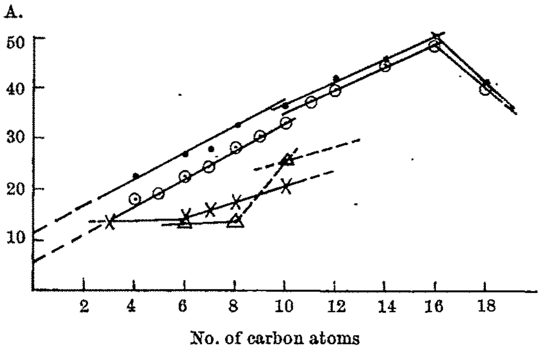

Fig. 1. Basal spacings plotted against chain-length of sorbed compound. ●, *n*-Amines with montmorillonite; ⊙, the same with graphitic acid; △, diamines with montmorillonite; ×, diamines with graphitic acid. Note that the diamines give half the slope of the *n*-amines, corresponding to only one layer of molecules

The actual value of the layer separation is, however, too low to accommodate two fully extended molecules. It seems necessary to assume, therefore, either that the free ends of the molecules overlap (to the same extent in each complex) or that the first two or three terminal carbon atoms, next to the amine group, are in contact with the sorbate layer, the rest of the molecule being turned around at right-angles. The last-mentioned supposition seems to us the more probable.

Beyond 16 carbon atoms, the spacing drops again, and this must apparently correspond to a tilting of the molecules. Unfortunately, only one amine in this range (octadecane-1-amine) was available to us.

We were rather surprised to find that completely analogous results are given by montmorillonite (upper graph of Fig. 1). These results are, however, not really in contradiction with those of Jordan[2], who found a flat orientation of long-chain amines, since in his case the amines were in ionic form, and in

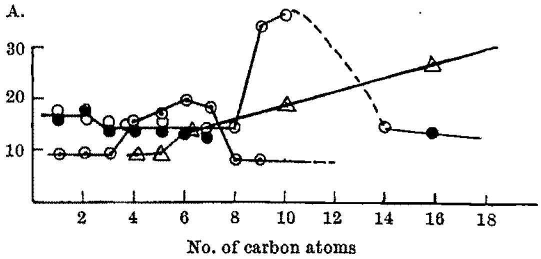

Fig. 2. As Fig. 1. ○, *n*-Alcohols with montmorillonite (Barshad); ●, same (MacEwan); ⊙, same with graphitic acid; △, glycols with graphitic acid

amounts roughly equivalent to the cation exchange capacity of the clay. In our experiments the amine was always in the form of the pure liquid. Recent work of Hofmann and collaborators[3], however, shows that even with ionic amines, β-type complexes can be formed.

Straight-chain alcohols also give β-complexes with graphitic acid, but over a much narrower range of chain-lengths (Fig. 2). These have been previously described[1], but in the light of our new results their nature becomes clearer. Barshad[4] has described what now seem to be β-type complexes formed by nonanol-1 and decanol-1 with montmorillonite. They are quite analogous to the graphitic acid complexes. Barshad's results are plotted in Fig. 2, together with ours.

Size Distribution of Tobacco Smoke Particles

Tobacco smoke from ordinary untipped proprietary branded cigarettes was collected directly on to various support films used in electron microscopy. 'Formvar' films were found to be most satisfactory in terms of particle resolution and film strength; with carbon, for example, the particles appeared to flow into one another more readily.

Smoke was allowed to impinge directly for about 5 sec. on to a 'Formvar'-covered electron microscope grid held within 1 cm. of the glowing end of a free-burning cigarette. Electron micrographs were taken at an instrumental magnification of 2,000 and the images of the smoke particles measured by an optical microscope (× 70) with a calibrated eyepiece graticule representing a spacing of 0·14μ on the original specimens.

Fig. 1*a* shows the resulting histogram of 1,200 particles obtained from three different electron microscope fields of view (such as Fig. 2*a*). The shaded area of each column represents the standard deviation obtained by using the results sequentially as 12 random samples of 100 observations each.

The histogram of Fig. 1*b* was obtained in a similar way for smoke collected 1 cm. from the mouth end of a cigarette (Fig. 2*b*). This was effected by puffing air from a small hand bellows through the cigarette from the burning to the mouth end, which simulates to some extent the conditions during the act of smoking. The extra dust particles observed in this case are recognizable by their shape and were ignored in the size analysis.

In order to test the filtering action, if any, of the lungs, the histograms of Figs. 1*c* and 1*d* were plotted, each of 800 particles. The former resulted from a brief inhalation, at the normal breathing-rate, while the latter resulted from a deep inhalation involving holding the breath for about 2 sec.

Although it may be tempting to draw immediate conclusions from histograms 1*a* to 1*d*, it became apparent during this work that the distribution of particle-size depended on the average age of the particles. As the age of the smoke increased, the particles tend to coalesce giving a greater proportion of larger particles at the expense of smaller particles, a fact easily demonstrated by collecting the smoke at different distances from the burning end of the cigarette.

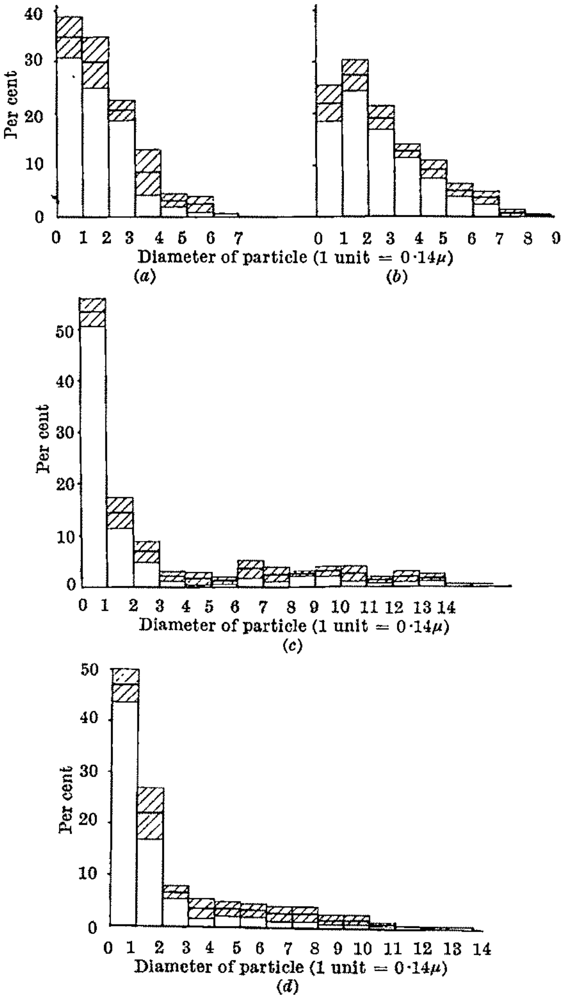

Fig. 1. Histograms showing particle-size distribution of tobacco smoke: (*a*) smoke taken directly from glowing end; (*b*) filtered through cigarette; (*c*) held briefly in lungs; (*d*) inhaled deeply

In order to obtain measurements of the aging of smoke, a glass tube, 10 ft. long and 2 in. in diameter, containing small ports at 1-ft. intervals along its length, was arranged horizontally and smoke from the glowing end of a cigarette was drawn at a speed of 1 ft./sec. along the tube by a pump at the other end.

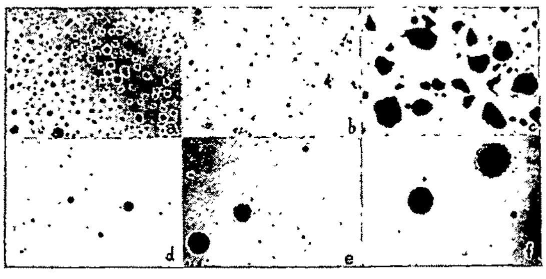

Fig. 2. Electron micrographs of tobacco smoke (× 700): (*a*) smoke taken directly from glowing end; (*b*) filtered through cigarette; (*c*) sedimented for several hours; (*d*), (*e*), (*f*) effect of aging for 1, 5, and 9 sec., respectively

The flow was laminar so that little exchange with the walls occurred. Microscope grids were placed in different ports to collect the smoke at different ages.

Two effects of age were apparent : first, the obvious increase in particle-size (Figs. 2*d*, *e* and *f*) and, secondly, a departure from regular circular cross-section and a greater boundary diffuseness, particularly for the smaller particles. This latter effect, together possibly with other effects as yet not elucidated, made it impossible to obtain histograms of acceptable consistency from field to field. Experiment showed that this was not due to evaporation of volatile components in the electron beam, as has been observed by Trillat and Cuzin[1]. Very long-period sedimentation under static air conditions produced quite different particle shapes, as shown in Fig. 2*c*.

It is clear that the 'age' of the smoke is of great importance, and its effects must be clearly understood before interpretation of distribution curves may be attempted, a situation which is not yet attained. Even so, 1,000 observations are too few for reliable conclusions to be drawn from them. Nevertheless, it appears that some filtering of the smaller particles, together with increase of size due to aging, is indicated by the greater number of larger particles observed after the smoke has passed through the cigarette ; also subsequent inhaling of smoke into the lungs causes the particle sizes to be redistributed in a different way, possibly by removal of the particles of size $\sim 0{\cdot}3\mu$.

It is noteworthy that only very rarely are droplets observed surrounded by a cloud of small satellites as occurs in many of the beautiful photographs presented by Kahler and Lloyd[2]. Such satellites, we believe, are essentially a product of the electrostatic precipitation technique employed, which is therefore unsuitable for determination of particle-size.

Helpful discussions with Mr. A. Horseman of the Imperial Tobacco Co. (of Gt. Britain and Ireland), Ltd., are gratefully acknowledged.

Detecting Volatile Airborne Droplets

Liddell and Wootten[1] have described a method for sampling fog droplets in a suitable form for measurement under the microscope. In this, microscope slides were coated with a gelatin film which incorporated a purified dye. When water droplets impinged on this film a characteristic dark crater-like ring remained after evaporation of the droplet. The film gave a permanent sample and when ideally prepared detected fog droplets down to 1μ. The ratio of the diameter of the ring to the original droplet was constant.

I have recently found that by eliminating the rather troublesome dye and viewing the pure gelatin film with positive phase-contrast the method becomes one of extreme reliability, simplicity and sensitivity. (Fig. 1*a*. These droplet traces are virtually invisible with ordinary illumination.) To support the film, microscope slides are used which have been cleaned in a hot acid cleaning mixture (for example, chromic–sulphuric) and stored in 'Tergitol' solution. A slide is wiped dry with a clean cloth and a thin film of a warmed gelatin solution of about 5 per cent concentration is spread evenly with a glass rod. The slide is gently heated until the film is quite dry, when it is ready for use.

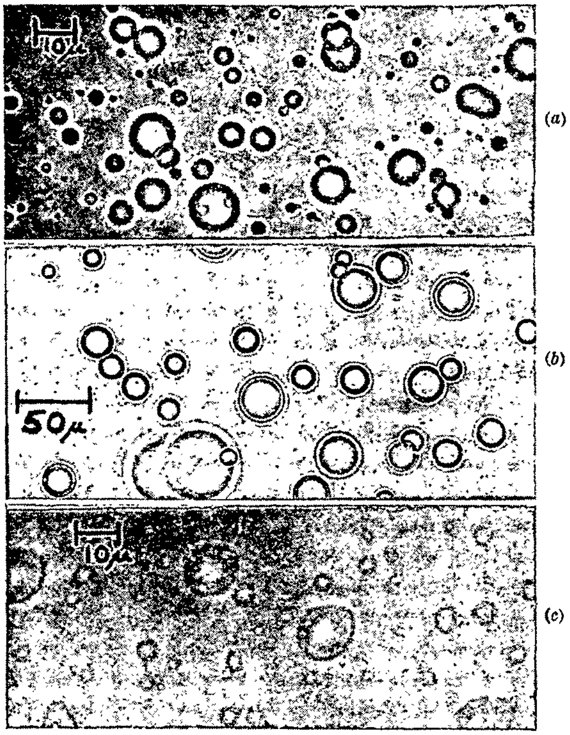

Fig. 1. Photomicrographs of traces left by volatile droplets. Scales refer to the original droplet diameters, not to the trace diameters. The samples were taken in a special form of two-stage reciprocating-slide impactor. (*a*) Fog droplets from second stage of impactor ; impacting jet velocity, 60 m.p.h. ; objective, 4-mm. phase-contrast. (*b*) Fog droplets from first stage of impactor ; jet velocity, 5 m.p.h. ; objective, 8-mm. phase-contrast. (*c*) Kerosene droplets on *R*230 silicone resin ; second stage of impactor, 60 m.p.h. ; objective, 8-mm. phase-contrast

For the smallest droplets, say $< 10\mu$, the thickness of the dry film does not seem to be critical, but for larger droplets the thickness is optimal at about 1μ (which can be judged by the interference fringes) as thinner films give very faint rings and thicker ones may give rather confusing halo effects as in Fig. 1*b*.

As an alternative to glass, films of clear gelatin on a clear flexible base may be obtained from photographic film manufacturers and are useful when curved impingement surfaces are required. Gelatin films may be used repeatedly or rejuvenated after long storage by rinsing quickly with distilled water and re-drying.

The method is of greatest value for droplets $< 10\mu$ where other methods such as the widely used magnesium oxide method[2] or impingement into oil or grease become unreliable. Sharp images of the traces of droplets well below 1μ in diameter are seen in Fig. 1*a*. It will be noted that in counting and sizing work, overlapping traces give no trouble except when a large drop completely overlaps and obliterates a small trace. For droplets $> 10\mu$ phase-contrast illumination is not essential, but the gelatin film method is not necessarily superior to the magnesium oxide method in this range.

In work in actual fogs using a special form of droplet impactor, as will be reported elsewhere, a factor was found for drop diam./ring diam. of 0·59, in agreement with laboratory calibration. In local fogs the method has revealed large numbers of droplets in the 1μ region as in Fig. 1*a*. A valuable feature is that the perfect optical quality of the gelatin film enables the insoluble content of the droplets, such as their condensation nuclei, to be seen and counted. The plurality of such particles in most droplets more than a few microns in diameter suggests that collision and coalescence of fog droplets is very common. A 50μ droplet may contain 50 or 100 discrete insoluble particles of 1μ or less.

Obviously, the principle of the water-sensitive gelatin film should be applicable to the detection of volatile droplets of other liquids, provided that a clear film, soluble in that liquid, can be prepared. A requirement known to me was the detection of kerosene droplets in combustion chambers. Screening tests of many kerosene-soluble substances were carried out and a satisfactory film was found in silicone resin *R*230 (I.C.I., Ltd.). This is spread on a slide and heated off in exactly the same way as for gelatin film. Contrast of the kerosene droplet traces after evaporation is not quite so good as for water on gelatin, but the phase-contrast microscope enables the traces to be seen clearly down to 2μ diam., representing droplets of 0·8μ, as the droplet/ring factor in this case is 0·4 (Fig. 1*c*).

There is no reason to doubt that suitable clear, soluble films could be found for the detection of a wide range of volatile liquids in the manner described.

Light Emission from Insulating Liquids due to Excitation by d.c. Fields near Breakdown

In scintillation counter applications[1,2], it is well known that dilute solutions of fluorescent organic materials, such as anthracene, in suitable organic solvents will absorb radiation and re-emit at a wave-length characteristic of the solute, when the liquid is excited by ultra-violet or high-energy particles.

While investigating pre-breakdown pulse activity and conduction currents in highly degassed and dehydrated transformer oil of Peruvian origin, it was found that visible light was emitted from the high-stress region at d.c. fields in excess of 600 kV./cm. So far as I am aware, this has not been observed previously in organic liquids. Tests were carried out in uniform fields between 1-cm. diameter nickel and stainless-steel electrodes, with a gap spacing of 89μ. The colour and frequency of the emitted light were similar to the blue fluorescence observed when the oil was excited with an ultra-violet source.

No detailed chemical results are available on the composition of the oil; but it is known that traces of unsaturated polycyclic aromatic compounds are present, and that these give rise to the fluorescence of the oil. In order to test the suggestion that light emission was due to excitation of molecules of this type, observations were made using spectroscopic grade hexane, and hexane samples doped with scintillation grade anthracene and *p*-terphenyl, dissolved at a concentration of 1 gm./l. No visible light was observed with pure hexane up to fields of 1·1 mV./cm., but light emission, characteristic of the dissolved impurity, was observed in the doped hexane samples.

Microscopic observations of this emission showed, for stresses from 600 to 950 kV./cm., filamentary luminous streamers which completely bridged the oil gap from cathode to anode, with no apparent change in intensity along its length. At higher stresses, the glow appeared to become diffuse over the high-field region.

The light intensity was found to increase in an exponential manner with increasing field, but no noticeable change occurred in the spectrum of the emitted light. Removal of the impurities was found to increase the breakdown strength. For example, fractional distillation of the oil, thus removing most of the fluorescent impurities, raised the breakdown strength of the degassed oil from 1,100 to 1,300 kV./cm. Similarly, the breakdown strength of the doped hexane was raised from 700 to 1,050 kV./cm. by removal of the added impurity.

It is possible that the light emission was due to micro-discharges in the oil rather than excitation of the fluorescent impurities in the liquid phase. By means of a metal bellows, pressure and tension was applied to the liquid in the test cell. No variation in the light intensity was observed, and fracture of the liquid did not occur when the liquid was subjected to tension at pre-breakdown fields in excess of 1,000 kV./cm.

These experiments indicate that fluorescent impurities, such as anthracene, which absorb energy by resonance of electron orbitals into higher states, may be excited by high d.c. fields in the liquid phase, and that the processes involved play some part in the processes which lead to electrical breakdown.

Acknowledgments are made to Prof. Humphrey Davies for the provision of facilities, to Dr. H. Tropper and colleagues of the Dielectrics Team for encouragement and discussion, and to the University of Queensland for the award of a Travelling Research Fellowship.

CHEMISTRY

Analysis of Hydrocarbons

The difficulty of separating a mixture of ethane, ethylene, propane and propylene on a single column in gas-phase chromatography has been commented on recently[1]. Drs. Barnard and Hughes also mention the difficulty of using some two-stage columns. This mixture can in fact be readily separated on a single column. If it is required to analyse only small samples, a column packed with alumina may be used, either thermostatted at one temperature[2] or by 'temperature-programming' the column[3]. When both

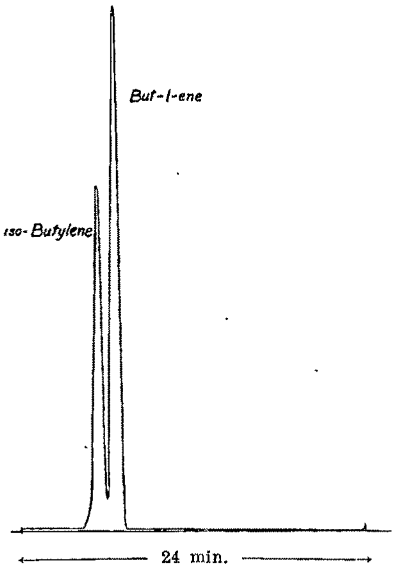

Fig. 1. 25-ft. acetonylacetone column ; 0° C. ; flow gas, hydrogen, 30 ml./min.

small and large samples have to be analysed, it is an advantage to use gas – liquid chromatography, and a single column of dimethylsulpholane on firebrick may be used[4]. Two-stage columns have also been used successfully to carry out this separation[4]; further, a commercial column is manufactured with which this analysis can be carried out[5].

In this laboratory this mixture has been analysed repeatedly on a single column, packed with acetonylacetone on firebrick (a copper coil, 25 ft. × ¼ in.) operated at 0° C. This column not only resolves the hydrocarbons mentioned, but also resolves nearly all the possible isomers of the C_2 to C_5 hydrocarbons, including many cyclic isomers, in a total running time of 1 hr. The column may be used to carry out the difficult analysis of *iso*butylene and but-1-ene in the presence of the other hydrocarbons. Fig. 1 shows the resolution obtained with this column and a mixture of *iso*butene and but-1-ene.

This column does not resolve 1,1-dimethyl*cyclo*propane and 3-methyl but-1-ene, two compounds which have closely similar boiling points. However, these compounds are easily separated using a solution of silver nitrate in ethylene glycol on fireclay. No difficulty has been experienced in using a short glass column (3 ft. × ¼ in.) packed with this material and attached to the end of the acetonylacetone-packed column. Such a double column allows this difficult separation to be carried out and still allows the other C_2 to C_5 hydrocarbons to be separated (see Fig. 2). A mixed column of these two packings has been used successfully, but was found to have a relatively short 'life' when compared with the double column.

DR. FREY'S letter is of considerable interest. We were, of course, aware of several methods reported in the literature for the separation of the C_2 and C_3 hydrocarbons. However, the purpose of our original communication was to direct attention to a *simple* method of separating the lower hydrocarbons, not involving any of the complexities of very long coiled columns, temperature programming or the necessity of maintaining temperatures below the ambient.

Our experiences with series columns had not been particularly successful, but the experiments with the *mixed* columns, using the same preparations of packing materials and identical packing procedures, were so fruitful that we thought it worth while directing attention to what was, to us at least, a new technique.

Structure of 'Cystine Disulphoxide'

ALTHOUGH the reactions of aromatic 'disulphoxides' have been studied by Smiles and his co-workers[1] and by Vinkler and Klivenyi[1] among others, the structures of these compounds remained uncertain until their infra-red spectra were examined by Cymerman and Willis[3]. The latter work confirmed earlier evidence that the compounds hitherto known as disulphoxides should be assigned the thiolsulphonate structure (I) rather than the disulphoxide structure (II).

$R—SO_2—S—R$ (I) $R—SO—SO—R$ (II)

Grushko and Guryanova[4] have recently made a study of some aliphatic analogues and conclude that they also have structures of type (I). The best-known aliphatic 'disulphoxide' appears to be that from cystine and this compound was assigned a structure of type (II) on chemical evidence[5], a structure which is still current in recent biochemical literature[6]. In connexion with other work we have obtained the infra-red spectrum of this compound and find it to have the characteristics of a thiolsulphonate rather than a disulphoxide. The strong bands at 1,110 cm.$^{-1}$ and 1,300 cm.$^{-1}$ agree well with those given by aromatic thiolsulphonates[3,7] and the spectrum showed no strong band near 1,050 cm.$^{-1}$ as exhibited by sulphoxides.

Using structure (II) Toennies and Lavine[5] found it necessary to introduce a series of intermediates to explain the reactions of 'cystine disulphoxide', but it is evident that these reactions can be more readily explained on the basis of structure (I). For example, 'cystine disulphoxide' reacts with cysteine to give cystine and cysteine sulphinic acid[6], and we have followed the course of this reaction by means of circular paper chromatography using *tert*-butanol – formic acid – water as solvent and ninhydrin in dry acetone as detecting agent. In our experiments the only bands appearing had R_F values of 0·04 and 0·20 (both due to cystine) and 0·35 (cysteine sulphinic acid). Examination of scale models suggests attack at the hexavalent sulphur to be sterically hindered, and in this reaction nucleophilic attack by the thiol group of cysteine might then be expected to occur at the adjacent sulphur atom, followed by fission of the SO_2—S bond of the thiolsulphonate and transfer of hydrogen. Other reactions of the thiolsulphonate can mostly be explained in a similar manner.

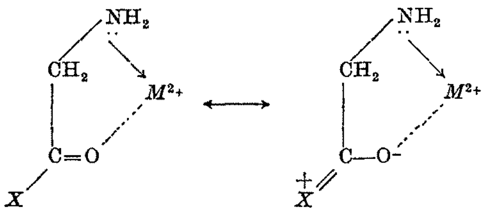
BIOCHEMISTRY

Relationship between Proton and Metal Binding by some Peptides, Amino-acid Amides and Amino-acids

THE stability constants of a series of ligands of the type, $NH_2.CH_2.CO.X$, with the ions Cu(II), Co(II) and Mn(II), have been measured in this laboratory[1], and it has been shown that, for any one of the metals, a linear relationship exists between log K_1 (first stability constant) and pK_a (acid dissociation constant of the amino-group)[2]. The group X can have a variety of structures ranging from O^- (glycine) to NH_2 and $NH.CH_2.COO^-$ (glycinamide and glycylglycine). From these observations it was concluded that the structure of the metal complexes was best represented thus:



For Cu(II) this structure only applies to the complexes initially formed, prior to the onset of additional acid dissociations which occur for some of the ligands.

The structure of peptide – metal complexes is of considerable importance in understanding the mode of action of proteolytic enzymes, and it is evident that additional experimental work is urgently required in this field. The formulation given above is consistent with infra-red measurements on urea complexes[3], but the only evidence for it is indirect and based on the observed relationships between log K_1 and pK_a. Since these types of correlation can, in some circumstances, be fortuitous[4], it was considered necessary to see if similar relationships occurred in other related series of ligands.

The results obtained for a series of sarcosyl ligands, $CH_3.NH.CH_2.CO.X$, are shown in Fig. 1. It can be seen that a linear relationship exists between log K_1

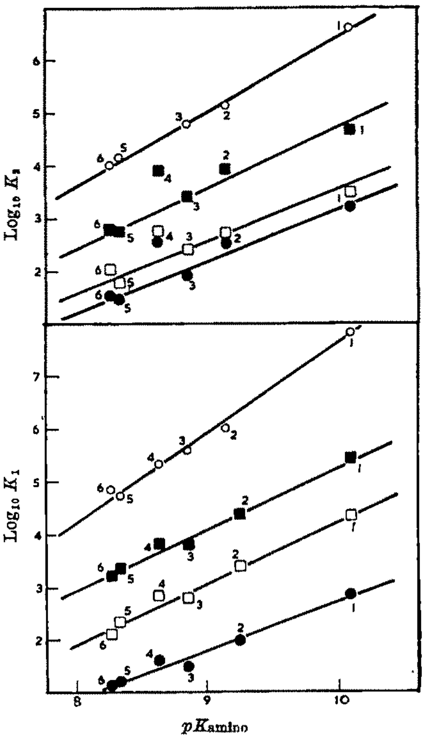


Fig. 1. Plots of log K_1 and log K_2 against pK_a for a series of sarcosyl compounds. ○, Cu(II); ■, Ni(II); □, Co(II); ●, Cd(II) (log K_1 − 1). 1, Sarcosine; 2, sarcosylsarcosine; 3, sarcosine dimethylamide; 4, sarcosyl L-leucine; 5, sarcosine amide; 6, sarcosine methylamide

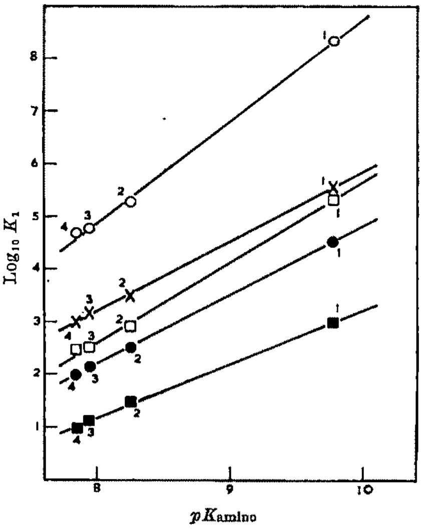

Fig. 2. Plots of log K_1 against pK_a for a series of leucyl compounds. ○, Cu(II); ×, Ni(II); □, Zn(II); ●, Co(II); ■, Cd(II) (log K_1 − 1). 1, Leucine; 2, leucylglycine; 3, leucylglycylglycine; 4, leucine amide

and pK_a for Cu(II), Ni(II), Co(II) and Cd(II); none of the constants shows significant deviation from the regression line. Similar straight-line correlations of log K_2 (second stability constant) and pK_a for the sarcosyl ligands are observed, with the single exception of sarcosyl L-leucine. A series of leucyl compounds have also been investigated and the results are illustrated in Fig. 2; these ligands show excellent straight-line correlations of log K_1 and pK_a for the complexes of Cu(II), Ni(II), Zn(II), Co(II), and Cd(II). It can safely be concluded that these linear relationships are not fortuitous, and they provide further evidence that the structures of the metal complexes of peptides and amino-acid amides are as shown above. It should be noted that, for any metal ion, a linear relationship between log K_1 and pK_a for a series consisting of all the glycyl, sarcosyl and leucyl compounds does not exist, nor is it expected. This suggests that the correlations observed for the individual series have physical significance.

The second stability constants of sarcosyl L-leucine with Ni(II), Co(II) and Cd(II) are too high to fall on the regression line of the other sarcosyl compounds. Presumably a stabilizing influence is present in the sarcosyl L-leucine 2 : 1 complexes which is absent in the other ligands and in the sarcosyl L-leucine 1 : 1 complexes. Sarcosyl L-leucine differs from the other ligands in possessing a large aliphatic side-chain; it is possible that the abnormally high stability of the 2 : 1 complexes of this compound is due to Van der Waals interactions between the side-chains of the pair of ligands co-ordinated to the metal. If so, the difference between the observed and predicted values of log K_2 gives a measure of the free-energy change associated with this interaction in aqueous solution; further investigations of this problem are intended.

Multiplicity of Histidine–Cu(II) Complexes

THE stability constants of the histidine complexes of several metals have been determined by several workers[1-4]. Satisfactory values of the stability constants can be calculated from titration data for all the metals investigated except Cu(II). Albert[3] suggested that the anomalies in the histidine – Cu(II) system are due to the planar configuration of cupric complexes in solution, which makes it impossible for all the three sites available for co-ordination (amino, imidazole and carboxyl) to be bound simultaneously to the metal ion. It has been shown[5] that other anomalies also occur in the co-ordination of Cu(II) by histidine.

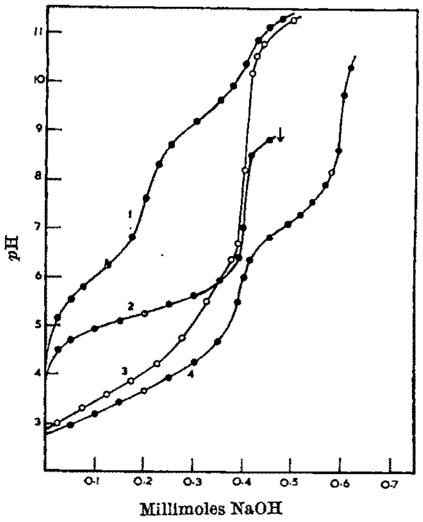

Fig. 1. Titration curves of histidine hydrochloride (0·2 m*M*) with sodium hydroxide (0·1 *N*): 1, no additions; 2, plus 0·2 m*M* cobalt chloride (for comparison); 3, plus 0·1 m*M* cupric chloride; 4, plus 0·2 m*M* cupric chloride

If the titration curves of histidine hydrochloride in the absence and presence of equimolar cupric chloride are compared (Fig. 1), it can be seen that the presence of Cu(II) produces one additional equivalent of acid. When the ligand – Cu(II) ratio is 2 : 1, the amount of base required to titrate all the acid species is the same as in the absence of metal. This means that an acid dissociation occurs from the 1 : 1 complex which is suppressed when the ligand to metal ratio is 2 : 1. These observations suggest that the additional acid ionization occurs from a water molecule co-ordinated to the copper atom of the 1 : 1 complex.

Attempts were made to calculate the stability constants on the assumption that the following equilibria were involved:

For 1 : 1 mixtures, $Cu^{2+} + L^- \overset{K_1}{\rightleftharpoons} CuL^+$ (1)

$$CuL^+ \overset{K_{c'}}{\rightleftharpoons} CuL + H^+ \qquad (2)$$

For 2 : 1 mixtures, $Cu^{2+} + L^- \overset{K_1}{\rightleftharpoons} CuL^+$ (1)

$$CuL^+ + L^- \overset{K_2}{\rightleftharpoons} CuL_2 \qquad (3)$$

$$\text{where } K_1 = \frac{[CuL^+]}{[Cu^{2+}][L^-]};\ K_2 = \frac{[CuL_2]}{[CuL^+][L^-]};\ K_{c'} = \frac{[CuL][H^+]}{[CuL^+]}$$

Satisfactory values of K_1 and K_2 could not be computed on these assumptions. Mixtures of histamine and cupric chloride showed the same phenomena on titration, but in this instance consistent values of K_1, K_2 and $K_{c'}$ could be obtained (log K_1 = 9·44, log K_2 = 6·39, $pK_{c'}$ = 7·00). Thus the difficulties in calculating the stability constants of the cupric complexes of histidine are not due to reaction (2).

If the interactions of histidine with Cu(II) only occur at any pair of the three available binding sites, singly protonated histidine (L^{+-}) can also act as a chelating species; then the structure of the 1 : 1 complex will vary with pH and the following equilibria must be considered when the ligand to metal ratio is 1 : 1:

$$Cu^{2+} + L^{+-} \overset{K_1}{\rightleftharpoons} CuL^{2+} \qquad (4)$$

$$CuL^{2+} \overset{K_c}{\rightleftharpoons} CuL^{+} + H^{+} \qquad (5)$$

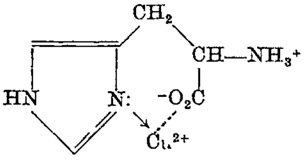
$$Cu^{2+} + L^{-} \overset{K_1}{\rightleftharpoons} CuL^{+} \qquad (1)$$

$$CuL^{+} \overset{K_c'}{\rightleftharpoons} CuL + H^{+} \qquad (2)$$

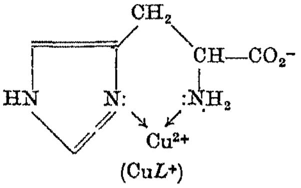
$$\text{where } K_1' = \frac{[CuL^{2+}]}{[Cu^{2+}][L^{+-}]} \text{ and } K_c = \frac{[CuL^{+}][H^{+}]}{[CuL^{2+}]}.$$

Quantitative analysis in terms of this reaction scheme yields consistent values of the equilibrium constants. The method of calculation was similar to that used for the glycylglycine – Cu(II) system[6] and will be reported in detail elsewhere. The following values were obtained: $\log K_1 = 10 \cdot 37$, $\log K_1' = 5 \cdot 02$, $pK_c = 3 \cdot 81$ and $pK_c' = 7 \cdot 19$.

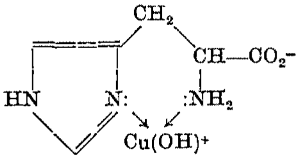
The most probable structures of the 1 : 1 complexes are:



(CuL^{2+})



(CuL^{+})



(CuL)

In the formation of histidine – Cu(II) 2 : 1 complexes, either of or both the ligand-chelating species (L,L^-) can be involved in interactions with CuL^{2+} and CuL^{+}. Thus there are three possible 2 : 1 complexes and the evaluation of the constants from titration data is extremely difficult.

We thank Dr. S. P. Datta for many valuable suggestions during the course of this work.

Feedback Control of Purine Biosynthesis by Purine Ribonucleotides

In recent years a number of biosynthetic sequences have been shown to be regulated by feedback mechanisms, which have been of two general types, the first involving regulation of the activity of an enzyme by an inhibitory effect of an end-product[1,2], the second involving regulation of the rate of synthesis of an enzyme by negative-induction, or suppression, of synthesis by an end-product[3,4]. In both types of mechanisms the inhibition involves the earliest step leading specifically to the synthesis of the regulating compound, which is itself a product normally present in the cell in appreciable concentration[1,2].

The existence of feedback control mechanisms in purine biosynthesis has been suggested by a number of observations, summarized elsewhere[5,6]. In these studies the presence of unlabelled purines suppressed *de novo* purine synthesis from labelled precursors. In no instance, however, was a precise characterization or localization of the control mechanism demonstrated.

In the biosynthesis of purines the first irreversible and specific step is that in which β-phosphoribosylamine is generated from α-phosphoribosylpyrophosphate and glutamine[7–9]:

$$\alpha\text{-phosphoribosylpyrophosphate} + \text{glutamine} + \text{water} \xrightarrow{Mg^{2+}} \beta\text{-phosphoribosylamine} + \text{glutamic acid} + \text{pyrophosphate}$$

The enzyme catalysing this reaction, phosphoribosylpyrophosphate amidotransferase[9], would appear to be a likely site for the operation of a feedback control.

We have purified α-phosphoribosylpyrophosphate-amidotransferase from the supernatant fraction of pigeon liver, by fractionation with ammonium sulphate, differential heat inactivation[9], and adsorption on to, and elution from, aged calcium phosphate gel. The reaction was followed kinetically by observing the rate of generation of glutamate, measured as reduction of the 3-acetyl pyridine analogue of diphosphopyridine nucleotide, in the presence of glutamic dehydrogenase[10], in 0·05 *M tris*(hydroxymethyl) aminomethane buffer, *p*H 8·0.

Evidence was secured for non-consecutive binding of α-phosphoribosylpyrophosphate and glutamine at independent binding sites. When concentrations of the former and of glutamine were varied independently at four levels each, and the velocity data plotted according to Frieden[11], the lines converged to a single

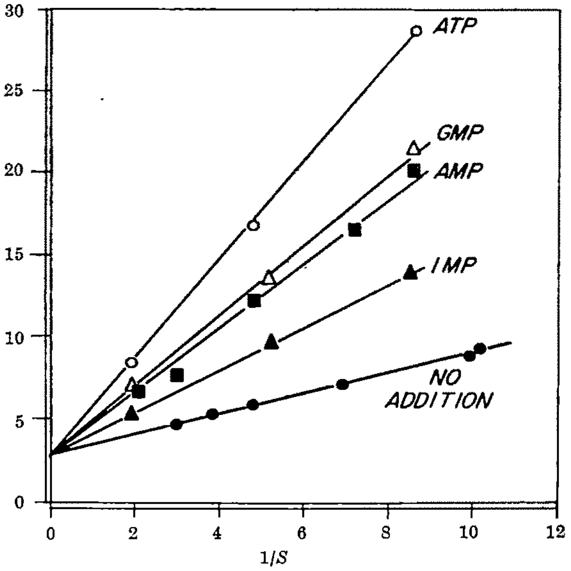

Fig. 1. Dependence of reaction velocity upon concentration of α-phosphoribosylpyrophosphate, and effect of inhibitors. Velocity was measured as increase in absorbance at 363 mμ per 10 min.; substrate in μmoles per ml. In all cases inhibitors were added in final concentration of 0·2 μmole per ml. Reactions were followed according to the standard assay, at room temperature, in 1-ml. quartz cells having a light path of 1 cm.

intercept on the extended X-axis in each case; that is, when S = α-phosphoribosylpyrophosphate, at various glutamine-levels, and when S = glutamine, at various levels of α-phosphoribosylpyrophosphate. The K_m for α-phosphoribosylpyrophosphate was $2 \cdot 3 \times 10^{-4}$ M and for glutamine was $1 \cdot 1 \times 10^{-3}$ M.

Many naturally occurring compounds were studied as potential feedback inhibitors of this enzyme. Inhibition was observed with 5-amino-4-imidazolecarboxamide ribonucleotide, inosine monophosphate, adenosine mono-, di- and tri-phosphates and guanosine mono- and di-phosphate. Selected results, plotted in Fig. 1, show competitive inhibition by inosine monophosphate, adenosine monophosphate, guanosine monophosphate and adenosine triphosphate of binding of α-phosphoribosylpyrophosphate by the enzyme. Average values for the dissociation constants of inhibitors are shown in Table 1. In other studies, the inhibitions were shown to be non-competitive with respect to binding of glutamine.

Table 1. MICHAELIS–MENTEN CONSTANTS OF SUBSTRATES AND DISSOCIATION CONSTANTS OF INHIBITORS

Substrate	K_m
Phosphoribosylpyrophosphate	$2 \cdot 3 \times 10^{-4}$ M
Glutamine	$1 \cdot 1 \times 10^{-3}$ M
Inhibitor	K_i
Adenosine triphosphate	$3 \cdot 7 \times 10^{-5}$ M
Adenosine diphosphate	$3 \cdot 9 \times 10^{-5}$ M
Guanosine monophosphate	$8 \cdot 6 \times 10^{-5}$ M
Adenosine monophosphate	$9 \cdot 0 \times 10^{-5}$ M
Inosine monophosphate	$1 \cdot 8 \times 10^{-4}$ M
Guanosine diphosphate	$3 \cdot 8 \times 10^{-4}$ M

Several related compounds were shown not to inhibit this enzyme. They included deoxy-adenosine monophosphate, deoxy-guanosine monophosphate, adenosine monophosphate-2′,-3′, inosine di- and triphosphate, guanosine triphosphate and ribose 5-phosphate, as well as purine bases and ribonucleosides and pyrimidine ribonucleoside monophosphates and triphosphates, and inorganic pyrophosphate. Thus, the inhibitory effects described would appear to be rather specific for certain purine ribonucleotides, of which adenosine di- and tri-phosphates are the most potent.

The regulation of activity of the amidotransferase by purine ribonucleotide products offers a mechanism for control of purine biosynthesis capable of responding rapidly to environmental changes. Such a control mechanism would account for the orderly synthesis of purine ribonucleotides and the maintenance of relative constancy of concentrations of purine ribonucleotides within the cell.

Effect of Substitution in the Side-Chain on β-Oxidation of Aryloxy-alkylcarboxylic Acids by *Nocardia opaca*

THE rate of β-oxidation of γ-substituted butyric acids by washed suspensions of species of soil *Nocardia* has been found to depend on the nature of the substituents[1,2]. γ-Phenoxybutyric is oxidized more slowly than γ-phenylbutyric acid, and substitution in the phenoxy group, particularly in the *ortho* position, further retards the process. β-Hydroxy acid intermediates were generally formed from γ-aryloxybutyric acids. It has now been found that the substitution of CH_3— for H— on the γ carbon atom of the γ-phenoxybutyric acids further retards β-oxidation.

In this work washed suspensions of *Nocardia opaca* (strain T_{16}), and the techniques of paper chromatography and infra-red analysis previously described[1] were used to study the conversion of DLγ-phenoxy-γ-methylbutyric, DLα-(4-chloro-2-methylphenoxy)-α-methylacetic, DLγ-(4-chloro-2-methylphenoxy)-γ-methylbutyric and DLε-(4-chloro-2-methylphenoxy)-ε-methylcaproic acids. We are indebted to Dr. B. J. Heywood of May and Baker, Ltd., for generous supplies of the first three compounds. DLε-(4-chloro-2-methylphenoxy)-ε-methylcaproic acid was prepared from DLγ-(4-chloro-2-methylphenoxy)-γ-methylbutyric acid by reduction to the alcohol (b.p. 146° C. at 0·1 mm.) with lithium aluminium hydride and formation of the bromide (b.p. 127° at 0·4 mm.) with phosphorus tribromide followed by condensation with malonic ester (in butanol). The dibutyl ester obtained decomposed to some extent on distillation, and the crude DLε-(4-chloro-2-methylphenoxy)-ε-methylcaproic acid obtained by hydrolysis and decarboxylation in the usual way was purified by conversion to the ethyl ester (b.p. 140° at 0·3 mm.) which was distilled and saponified. The syrupy product (found C, 61·35; H, 6·86, $C_{14}H_{19}O_3Cl$ requires C, 62·02; H, 7·05 per cent) gave only a single spot on the paper chromatogram, but this was not well separated from DLγ - (4 - chloro-2 - methylphenoxy)-γ - methylbutyric acid.

Table 1 indicates that DLγ-phenoxy-γ-methylbutyric acid is metabolized at a slower rate than γ-phenoxybutyric acid, when these substances are exposed to suspensions of T_{16} in the Warburg flask.

Table 1

Substrate	μlitres oxygen/3 hr.
None	55·7
M/250 γ-phenoxybutyric acid	123·3
M/250 γ-phenoxy-γ-methylbutyric acid	86·9

Each vessel contained 1·0 ml. cell suspension (10·6 mgm./ml. dry wt.) + 0·5 ml. M/15 phosphate buffer pH 7·2 + 0·5 ml. substrate (as sodium salt) + water to give a final volume of 2·5 ml. The centre well had 0·2 ml. 5 per cent potassium hydroxide.

Confirmation of this was obtained in a large-scale experiment in which cells were incubated with these compounds. Paper chromatography of ether extracts of suitable aliquots showed that whereas γ-phenoxybutyric acid had been completely converted in 3 days, only about 60 per cent of DLγ-phenoxy-γ-methylbutyric acid had been converted. Infra-red analysis of the final products confirmed that γ-phenoxybutyric acid had been completely converted to phenoxyacetic acid, which was isolated in crystalline form, but that 50 per cent of the product from γ-phenoxy-γ-methylbutyric acid consisted of the β-hydroxy acid. A small amount of phenoxy-α-methylacetic acid was also present. After a further addition of cells comte oxidation to the acetic acid was achieved, wing that both D- and L-isomers had been meta-ized.

A large-scale experiment was also set up to study behaviour of DLα-(4-chloro-2-methylphenoxy)-α-thylacetic acid and DLγ-(4-chloro-2-methylphen-γ)-γ-methylbutyric acid. After six fresh additions washed cells at 7-day intervals it was found that substantial change had occurred in either. evious work[1] with γ-(4-chloro-2-methylphenoxy) tyric acid under these conditions showed conver-n to the corresponding β-hydroxy acid. The fore-ing experiments clearly demonstrate that the com-unds with the unbranched side-chain are much re easily oxidized than those with a branched side-ain.

This effect, as with ring substitution[1], is most arked with a short fatty acid side-chain. Thus it found in Warburg experiments that there was a l increase in oxygen uptake by cells of T_{16} DLε-(4-chloro-2-methylphenoxy)-ε-methylcap-l when compared with DLγ-(4-chloro-2-noxy)-γ-methylbutyric acid suggesting a rapid breakdown of the side-chain of the s was confirmed in a large-scale incubation where it was shown by infra-red analysis -chloro-2-methylphenoxy)-ε-methylcap-d been converted to DLγ-(4-chloro-2-xy)-γ-methylbutyric acid in 4 days. crystalline product was isolated.

these results suggest that many plants ze γ-(4-chloro-2-methylphenoxy) butyric il to convert DLγ-(4-chloro-2-methyl-nethylbutyric acid to the herbicidal -2-methylphenoxy)-α-methylacetic acid[3].

Crystallization of Gramicidin

GRAMICIDIN, an antibiotic produced from a strain of *Bacillus brevis*, is reported to be soluble in the lower alcohols and to be crystallizable from dioxan and/or acetone[1-3]. With some special batches of gramicidin, Synge[4] has obtained a few crystals from ethanol after slow vapourization of the solvent.

In all manuals a melting point of 228–231° C. is quoted for crystalline gramicidin.

All batches of gramicidin so far tested by us have yielded crystals from ethanol not only after vapourization of the solvent but also on prolonged standing at room temperature.

X-ray diffraction studies of this product and of that crystallized from acetone revealed essentially the same basic picture. However, the diffraction pattern of the former was much easier to see, disclosing a larger number of lines and thus indicating better structure of crystals obtained from ethanol (Table 1).

Table 1

Line No.	Acetone form		Ethanol form	
	Distance (cm.)	Description	Distance (cm.)	Description

Further investigations revealed distinct differences in solubilities and melting points of the two 'gramicidin forms'. To obtain additional information, we have re-crystallized the 'acetone form' from a number of solvents. Some characteristics of the most thoroughly investigated products are listed in Table 2.

The solubility of four 'gramicidin forms' in 96 per cent ethanol was investigated at different temperatures (Fig. 1). In order to avoid too much interference by transformation processes in all these investigations, a short equilibration period (1-hr. shaking) had to be used. Even under such conditions, it was difficult to obtain consistent results—especially with different batches.

Recrystallization was also carried out with mixtures of solvents. The melting point followed that obtainable with the solvent last vapourized in the process.

The conclusion seems to be that the solvent used for the crystallization, or the solvent persisting longest during the process of drying, determines the melting point and the solubility of the final product. It is our impression that in the case of crystallization from acetone a considerable number of solvent molecules are embedded into the crystalline structure but removed upon drying. This is indicated both by the voluminous consistency in acetone of the slurry and the moist cake—not observed in the case of crystallization from alcohols, higher ketones, ether or cyclic solvents—and the marked influence of the drying conditions upon the melting point. Also the inferior crystalline structure and lower melting point

Table 2

Recrystallized from	Solubility at room temperature		Melting point, corrected (° C.)
	In ethanol	In methanol	
Acetone	21·0%	>25·0%	228–231* 232–235*
Methanol	3·5%	3·9%	244–247
Ethanol	3·3%	>25·0	247–249†
n-Butanol	2·4%	39·0%	246–248

* Depends on the drying conditions, the higher melting-point range being obtained in a very slow drying process.

† Recently we have obtained a melting point of 251–253° C. (corr.) with a batch recrystallized several times from ethanol.

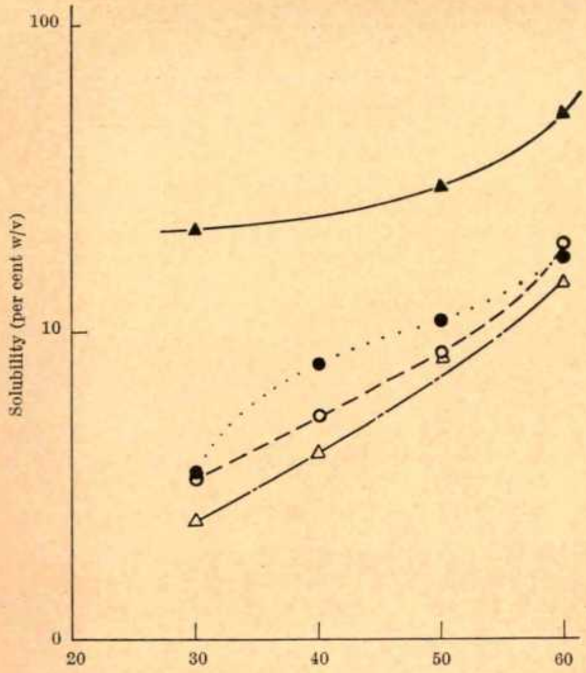

Fig. 1. ▲, Acetone form; ●, methanol form; ○, ethanol form; △, *n*-butanol form

indicate a kind of deterioration of the structure which might be due to the removal of acetone. This seems to confirm Hodgkin's[5] hypothesis, at least in the case of acetone.

The different 'forms' of gramicidin may, under proper conditions, be quantitatively (on weight as well as biopotency basis) transformed into each other.

We are indebted to Dr. M. Danø, Department of Mineralogy, University of Copenhagen, for the X-ray analysis.

ANIMAL PHYSIOLOGY

Ganglionic Block and Monoamine Oxidase Inhibitors

RECENTLY, certain monoamine oxidase inhibitors have been reported to be useful in the treatment of hypertension, and some of the clinical data suggest that ganglionic blockade may be caused by such agents[1,2]. To date, however, there have been no pharmacological studies to support these clinical impressions. In re-examining data, presented by Gertner, Paasonen and Giarman[3], demonstrating the presence of 5-hydroxytryptamine when the superior cervical ganglion was perfused with iproniazid, it w seen in these experiments that iproniazid block ganglionic transmission. Furthermore, a defin dosage–response relationship was found; minin blocking effects were seen with 100 μgm. of iproniaz per ml. of perfusion fluid and complete blockade wh 400 μgm./ml. was used. The appearance of 5-hydrox tryptamine in the perfusate occurred a consideral time after the appearance of ganglionic blockade. ascertaining the effects of the *p*-tolyl ether of cholir the authors found that it, too, would block trar mission, but no 5-hydroxytryptamine appeared the perfusate.

Recently, in examining two additional pote monoamine oxidase inhibitors, β-phenyl *iso*propy hydrazine (*JB*–516, Lakeside Laboratories)[4] and t alkaloid harmine[5], it was found that both these agen blocked transmission, in a manner similar to ipr niazid. When the ganglion was perfused wit Locke's solution containing 10 μgm./ml. of β- *iso*propylhydrazine, a gradual block of trans resulted, which increased in magnitude over [illegible] of 1 hr. This block could be reversed by [illegible] to drug-free Locke's solution. β-Phenyl [illegible] hydrazine at 20 μgm./ml. produced a mor [illegible] greater block of transmission, and in [illegible] concentration to 50 μgm./ml. resulted [illegible] and immediate blockade, which was g [illegible] partially reversible if the ganglion was [illegible] this substance for periods of an hour. [illegible] concentrations of 10 μgm./ml. produce [illegible] transmission which was similar to th [illegible] β-phenyl *iso*propylhydrazine. This effect [illegible] over a period of 1 hr. and completely rev [illegible] increasing the concentration of harmine t [illegible] a complete block was observed in 15 min. [illegible] entirely reversible. In all these experim [illegible] of the perfusion fluid was very carefully [illegible] 7·3.

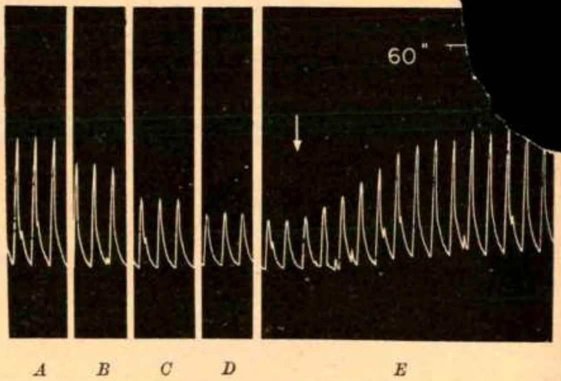

Fig. 1. Effect of harmine on the superior cervical ganglion of the cat. Contractions of the nictitating membrane to stimulation of the cervical sympathetic trunk at 0·5 m.sec., 10 c.p.s. and maximal voltage (*A*); control (*B*); 15 min. after start of perfusion with harmine, 10 μgm./ml. (*C*); 30 min. later (*D*); 1 hr. later (*E*). At arrow Locke's solution lacking the inhibitor was re-instituted

β-Phenyl *iso*propylhydrazine is a substance similar in structure to iproniazid. The action of this compound in blocking transmission would therefore appear to be analogous to the action of iproniazid, another hydrazine. Isoniazid, however, another hydrazine derivative, which lacks the ability to inhibit monoamine oxidase[6], was found to be without action on the ganglion in concentrations up to 400 μgm./ml. Harmine is of a completely different cæmia[9] in which there is a deficiency of an essential substrate for the brain. The results of this study resemble those of insulin hypoglycæmia, and suggest that perhaps with pyridoxine deficiency also there is interference with the supply or utilization of an essential substrate for the brain.

The convulsions caused by pyridoxine antagonists in experimental animals have been found to be associated with a decreased level of γ-amino-butyric acid in the brain and to be arrested by administration of this compound[2]. γ-Amino-butyric acid is formed only in the central nervous system by the decarboxylation of glutamate, which is dependent on pyridoxal phosphate, but there is some uncertainty whether it functions in the brain as a neurohumoral mediator of cerebral inhibitory functions or as a substrate for metabolic oxidations[1,10]. In the former case, its deficiency might be expected to lead to convulsions with increased consumption of cerebral oxygen because of increased neuronal functional activity; in the latter, reduction in cerebral metabolic rate would be expected. The results of this study tend to support the latter hypothesis.

Arginine Esterase Activity of 'Blood Thromboplastin'

THE presence of a thromboplastin-generating system in blood has been shown by Biggs, Douglas and Macfarlane[1]. It is now recognized that at least six different factors participate in the formation of 'blood thromboplastin' and that a series of reactions resulting in the production of hypothetical intermediates such as product I and product II (Table 1) precede the appearance of the active prothrombin-converting substance[2,3].

Table 1

System	Tosyl – arginine methyl ester esterase activity
Product I	
Aged plasma treated with barium sulphate	
Serum	
Calcium chloride	
Buffer	52
Product II	
Product I	
Azolectin	71
'Blood thromboplastin'	
Product II	
Purified human plasma *Ac–G*	107

Plasma and serum components were prepared from fresh normal human blood. '*Ac–G*-free' plasma was prepared by incubating plasma for 24 hr. at 37° C. This plasma was treated with barium sulphate until it had a prothrombin time of at least 60 min. The serum was incubated at 37° C. until it did not produce a fibrin strand for 60 min. when added to purified bovine fibrinogen. A 30-mgm. per cent aqueous emulsion of azolectin (soybean phosphatides) served as a platelet substitute. Purified human plasma *Ac–G* was prepared according to Lewis and Ware (ref. 4). Suitable dilutions of the various components were made with 0·025 *M tris* buffer, *p*H 8·2. Pre-incubation of the generating systems was allowed to proceed for 6 min. at 37° C. Tosyl – arginine methyl ester esterase activity levels were determined for a 90-min. period at 37° C. using a modification of the method of Rhodes, Hill and Feeney (ref. 5).

We have found that complete thromboplastin-generating systems prepared with normal human plasma and serum components exhibit tosyl–arginine methyl ester esterase characteristics and that similar, although less marked, activities were also shown by product I and product II mixtures (Table 1). Although special precautions were taken in this work to ensure the absence of prothrombin and thrombin in both plasma and serum components of the thromboplastin-generating mixture, the possibility that a small amount of thrombin was formed during the pre-incubation of the complete system cannot be excluded.

The addition of soybean trypsin inhibitor to the complete thromboplastin-generating system following its pre-incubation resulted in marked inhibition of its tosyl–arginine methyl ester esterase activity. Essentially identical results were also obtained when the thromboplastin-generating system was made up with plasma and serum components from patients maintained on long-term prothrombin-depressant anticoagulant therapy. When, on the other hand, plasma and serum components from patients with histories of thrombo-embolic episodes were used the esterase activity still measurable in the presence of soybean trypsin inhibitor is more than twice that found with the other two groups (Table 2).

Soybean trypsin inhibitor does not interfere with the clotting activity of purified thrombin and we have

Table 2

Type of patient	Tosyl – arginine methyl ester esterase activity of 'blood thromboplastin'	Tosyl – arginine methyl ester esterase activity of 'blood thromboplastin' in presence of SBTI*
'Normal'	89 (70–127)	14 (0–36)
Long-term anticoagulant therapy	74 (53–90)	8 (0–12)
Past history of thrombo-embolism	111 (52–173)	43 (22–69)

* Soybean trypsin inhibitor

The figures represent the averages of the results obtained with six different patients in each of the three groups, and the figures in the brackets show the range of the individual determinations. Soybean trypsin inhibitor was added to the system following the 6-min. pre-incubation period to give a final concentration of 60/μgm./ml. Other details of the procedure were the same as those described in the legend for Table 1.

observed a similar lack of inhibition of the activity of its tosyl–arginine methyl ester esterase. Whether or not the thromboplastin esterase activity still measured in the presence of the inhibitor is actually due to thrombin is not known at present, although the clotting of purified fibrinogen by the complete thromboplastin-generating system suggests that this may, in fact, be the case. Evidence for the formation of trace amounts of thrombin in a similar pre-incubation system has been presented by Johnston and Jensen[6].

The findings reported here are of particular interest in view of some recent observations on differences in activities of tosyl–arginine methyl esterase of freshly collected, citrated plasmas of the same three groups of patients[7]. The possible relationship between the two sets of observations is now being studied and will be reported in greater detail elsewhere.

This work was supported by the Medical Research and Development Board, Office of the Surgeon General, Department of the Army, under Contract No. *DA*-49-007-*MD*-275.

■

Aortic Medial Calcification and Lowered Metabolism in Ground Squirrels

THIS study was intended to test in mammals the concept that some animals have a potential physiological limit of energy which may be utilized at different rates depending upon environmental temperatures. McArthur and Baillie[1] were able to triple the life-span of *Daphnia* (Crustacea) by a 20-deg. drop in temperature. The total heart beats during the life of the *Daphnia* differed by less than 2 per cent whether the duration of life was a few days due to high temperature or several months due to low temperature. Similarly, Carlson and Hoelzel[2] prolonged the life-span of white rats by reducing their metabolism by partial starvation.

In our investigation, two groups of thirteen-lined ground squirrels: a control group (N-14) always maintained at room temperature, and a group which hibernated (N-15 → 12) for 4 months each of three winters under controlled conditions (12 months of hibernation). All animals (with one accidental exception) were born in the laboratory, and each litter was divided between control and experimental groups. Each hibernator when in the cold showed bouts of deep hibernation for about 6 days at a time in the classic state of very reduced body temperature, heart-rate, breathing-rate and metabolism. The periodical awakening lasted about 12–24 hr. Observation methods and results have been detailed elsewhere[3,4]. During the second winter of hibernation one hibernator died and two others died during their usual summer stay in the warm room, which had heated up briefly to more than 32° C. due to a spell of hot weather. Since no control ground squirrels died of natural causes, we may speculate that for some ground squirrels hibernation may be directly or indirectly a stress. At the end of the hibernation period of the third winter, when the specimens were 3 years old, physiological measurements were made at room temperature on 12 hibernators and on the 14 control squirrels. Then both groups were killed, and a series of biochemical and morphological tests were made. At this time the squirrels should be considered at least middle-aged although the life-span of the thirteen-lined ground squirrel has not been determined. 13 of the series (5 hibernators and 8 non-hibernators) were examined histologically. The results were checked against 53 recently caught wild ground squirrels. The rest of this report will concern only the blood vessel findings in the histological observations. Some of the other results have been reported earlier[3,4].

Table 1. DISTRIBUTION OF AORTIC MEDIAL CALCIFICATION IN GROUND SQUIRRELS RAISED IN LABORATORY (N = 13)

Aortic calcification	No calcification
Hibernators:	
Male*	Male (*a*)
	Female (*a*)
	Female
	Female
Non-hibernators:	
Female (*a*)†	Male
Male	Male (*b*)
Female	Female (*b*)
Female	Female

* More than four years old (trapped as adult); all others are three years old (born in laboratory).
† Letters, if present, identify litter mates.

Calcified plaques were observed in the media of the aorta in 5 ground squirrels (see Table 1). The lesions were histologically indistinguishable from human vascular medial calcification (also referred to as Mönckeberg's sclerosis or senile arteriosclerosis). The anatomical location, however, differed. In ground squirrels the lesion was found only in the proximal aorta (absent in the abdominal aorta and ileofemoral arteries) while the human lesion is more frequent and more severe in the larger muscular arteries of the extremities. The plaques were found in the inner three-quarters of the aortic media (Fig. 1). The largest plaques were two-thirds of the circumference of the aorta and three-quarters of the thickness of the aortic wall. Most plaques were sufficiently calcified to obscure all cytological detail in hæmatoxylin- and eosin-stained sections; after decalcification with hydrochloric acid, elastic lamellæ and smooth muscle cell nuclei were distinguishable in some, but others showed only amorphous debris. In some sections near the plaques there were many bluish, apparently calcific granules both along the elastic lamellæ and diffusely distributed in smooth muscle cytoplasm; also a few barely visible, bluish-staining granules (calcium ?) were found in the proximal aorta of 2 hibernators and the 1 non-hibernator all free of plaques. In some aortæ there was swelling and vacuolization of some smooth muscle cell cytoplasm, not consistently associated with calcification.

The findings in the laboratory animals were checked against the 53 wild ground squirrels. These were studied and dissected, and at least 50 per cent were determined to be more than one year of age. None

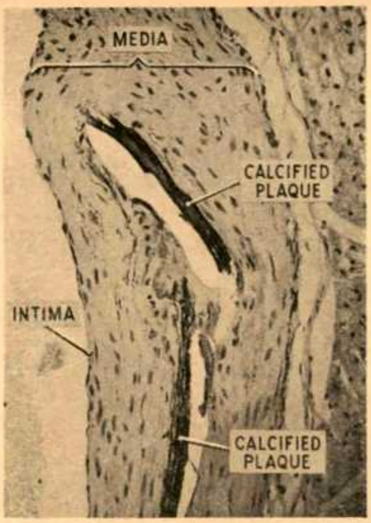

Fig. 1. Medial calcification in aorta of ground squirrel which did not hibernate during its life-span (three years). (× 110)

had aortic or ileofemoral arterial medial calcification. There was no atherosclerosis in any of the squirrels studied, wild or raised in the laboratory

Spontaneous aortic lesions like those in the ground squirrel have been described by Fox[5] in rabbits, cows, horses, wild canines, cats, marsupials and shore birds. It was not possible to determine from his account whether his material was more comparable to our laboratory series or to the field series. The lesions have also been produced experimentally by several methods, all relatively harsh[6]. Apparently diet did not produce the lesions in the present series since there was no evidence from a separate study of the teeth, weights and other indices, of any dietary abnormality in the laboratory squirrels. Spontaneous medial calcification increases with age in man[7,8], in the rabbit[9] and in the cow[5]. The same relationship would be expected in ground squirrels raised in an environment as nearly normal as laboratory conditions permit; yet none of the 3-year hibernating ground squirrels showed medial calcification (although found in 50 per cent of the controls). This evidence suggests that lowering metabolism (by hibernation) in some way reduces the occurrence of medial calcification in ground squirrels in the laboratory and probably also in the field environment of this local geographical area.

This investigation was supported by a grant from the National Science Foundation.

Reduced Activity of Histaminase in Rats sensitized by *Bordetella pertussis*

SINCE Parfentjev and Goodline[1] published their work on histamine hypersensitivity induced by inoculation of *Bordetella pertussis* (reviewed by Kind[2]) a number of papers on the subject have appeared; but little has been reported of the related biochemical changes in connexion with susceptibility to histamine. Inactivation of histamine by lung tissues from mice inoculated with *B. pertussis* was reported by Kind *et al.*[3] to decrease as compared with tissues from uninoculated mice. But this interesting result was not repeated by the same authors. More recently, Fishel[4] has examined changes in amino-acids, histamine and glutathione contents in various organs from inoculated mice, revealing no specific changes referable to histamine hypersensitivity. The present communication deals with the results concerning reduced activities of histaminase in tissue of rats inoculated with *B. pertussis*.

Bordetella pertussis, phase 1, No. 18-323, was cultivated in a synthetic medium originally described by Kuwajima *et al.*[5] at 37° C. for 96 hr. The grown cells were centrifuged and the supernatant was incubated in the presence of 1/5,000 merthiolate at 37° C. for 48 hr. to detoxify lethal toxin. Male albino rats (Wistar strain) weighing 100–200 gm. were sensitized by a single intraperitoneal injection of 3 ml. of the supernatant. Tissues from the inoculated and the uninoculated rat were taken on the fifth day and homogenized in a glass homogenizer with 5 vol. of cold phosphate buffer (*p*H 7·4, *M*/15). A supernate obtained by centrifugation of the homogenate was dialysed against the same buffer at 4° C. for 20 hr. and assayed for histaminase by the method of Kapeller-Adler[6]. The standard assay system contained 5·5 ml. of the supernatant, 4·0 ml. of phosphate buffer (*p*H 7·4, *M*/15), 3·0 ml. of $1{\cdot}43 \times 10^{-3} M$ indigo disulphonate (Merck), 20 μgm. of flavine adenine dinucleotide and 3·0 ml. of $5{\cdot}5 \times 10^{-3} M$ histamine dihydrochloride or water. One drop of chloroform was added as a preservative. 2½ ml. of an aliquot taken at each incubation period was assayed in duplicate for histaminase activity.

Table 1. HISTAMINASE ACTIVITY OF LUNGS OF RATS SENSITIZED WITH *B. pertussis*

Normal	Sensitized
622*	257*
789	330
697	330
856	293
767	—
Mean 746 ± 112	330 ± 55·7

Statistically significant ($F_s = 85{\cdot}3 > F'_7 (0{\cdot}01) = 12{\cdot}25$).

* Histaminase activity: expressed as μgm. histamine degraded per gm. tissue, in 24 hr., at 37° C.

As shown in Table 1, the histaminase activity of sensitized rats was significantly reduced as compared with normal rats. In six subsequent experiments with 3 animals per group, a decrease in histaminase activity was again produced and examined statistically (ratio for decrease between the inoculated and the uninoculated rats is 59·5 ± 10·5 per cent for lung, 38·0 ± 14·3 per cent for liver). With tissues other than the lung and the liver, no definite histaminase activity was detected because the activity of such tissues was too low and because of the relatively higher blank titres. The decrease in histaminase observed can scarcely be ascribed to a general depression of the metabolic activity, or to a shortage of prosthetic groups, because the inoculated animals were apparently healthy and enzymes other than histaminase, such as succino-oxidase or monoamine oxidase, showed no significant difference in their activities between the normal and the inoculated rat liver. The succino-oxidase activity was 274 and 296 µl. oxygen/100 mgm. tissue in 30 min. in the normal and the inoculated liver respectively. Monoamine oxidase was assayed with tyramine according to Creasy's method[7]. The uptake of oxygen was 237 and 220 µl./gm. tissue in 30 min. in the normal and the inoculated liver respectively. It is considered that reduced activities of histaminase may provide a clue to the explanation of histamine hypersensitivity in animals inoculated with *B. pertussis*.

SINCE the work described above was carried out we have investigated the reduced inactivation of histamine by liver and brain from mice sensitized with *B. pertussis*. Histamine was added to a homogenate of the organs. Then the amount of histamine remaining after various intervals of incubation at 37° C. was determined by extracting histamine by a modified McIntire's method[1] and using guinea pig ileum. The extract responded to atropin and antihistamines in much the same way as histamine did. The liver and brain of sensitized mice showed a statistically significant reduction in the histamine-inactivating activity over non-sensitized mice.

The failure of reproduction of a reduced inactivation of histamine in mice sensitized with *B. pertussis*, as reported by Kind and Woods, may be due to their use of a more dilute homogenate than ours and a crude mixture instead of histamine extract.

Secretion of Two Types of Saliva by an Aphid

NEARLY all phytophagous Hemiptera, including aphids, secrete a salivary material which coagulates rapidly on ejection to form a 'stylet-sheath' enclosing the path of the stylets in food materials and even in agar gel[1] and liquids[2]. It has been reported[3] that some Heteroptera secrete in addition a separate watery and water-soluble saliva which is emitted and sucked back both on the surface of substrates and within them. However, opinions differ on whether jassids secrete one type of saliva from which water-soluble substances diffuse before it gels[4] or two distinct types of saliva[5]; and among the Homoptera generally, only a sheath-forming secretion has hitherto been demonstrated conclusively.

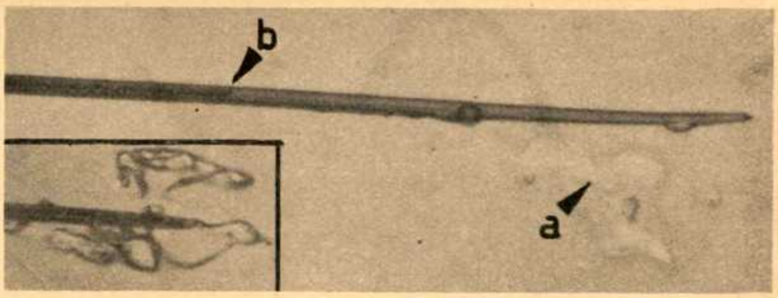

Fig. 1. Photomicrographs of the stylet bundle (with food canal uppermost) and salivary secretions of *Aphis craccivora*. (*a*) Sheath material secreted on to the underlying glass slide; (*b*) the meniscus of a watery secretion which has been discharged from the salivary canal and sucked back into the previously empty food canal. Inset, sheath material being extruded from the tip of the stylet bundle

The salivary secretions of aphids are of particular interest since they can act as vehicles for many plant viruses and may also inhibit them[6]. Due to the smallness of the insects it is difficult to determine whether, during feeding, they emit any non-coagulating saliva in addition to the sheath-material; but the following observations indicate that *Aphis craccivora* Koch does in fact produce two types of salivary secretion.

The insects were cemented by the dorsum to a pinhead, anæsthetized with carbon dioxide, and secured so that the stylets, which were first slipped out of the rostrum, lay flat on a clean, dry glass surface. It was observed under the microscope that as soon as the insect became active again, the contents of the food-canal were suddenly sucked back, leaving the canal totally or partially filled with air. The mandibles would then begin to slide backwards and forwards over the maxillæ, and almost invariably a highly viscous secretion was discharged in a manner suggesting the extrusion of artists' oil paint from a tube. This secretion solidified almost immediately it left the stylets and was evidently sheath material. Occasionally, it was also possible to see sudden flushes of watery liquid issuing from the tip of the stylets, but the most convincing evidence that another secretion was produced was the sudden sucking back of liquid up the empty food-canal. The rapid movement of this liquid and its appearance at times when no sheath material was being discharged precluded the possibility that it was the latter secretion. Further, since no liquid passed down the food-canal, regurgitation of gut contents could not have occurred. It is evident, therefore, that *Aphis craccivora*, similarly to Heteroptera, secretes a watery saliva distinct from the material which forms the stylet-sheath.

Bloat in Cattle

Much experimental work has been done on the causes of legume bloat in cattle and the prevention of its occurrence in the field (for reviews see Johns[1]). Several substances have been isolated from the feed or the animals' saliva, and have been reported to be responsible for the foam in the rumen of a bloated cow; but it has not been shown that any of these substances occur in the foam found in the rumen, and no attempt has been made to isolate the surface-active compound responsible for the foam directly from the rumen contents of a cow grazing clover or lucerne.

In my experiments, serial samples of rumen fluid were taken from cows through a permanent fistula, commencing before the beginning of either eating freshly cut clover and lucerne in the stall or grazing a new area and continuing for 6 hr. The pH, eH, total volatile fatty acid and ammonia nitrogen of the samples were determined. The remaining liquor was treated with 'Hyflo Supercel' to aggregate the suspended particles, and the straw-coloured filtrate was collected at the pump. The filtrate was found to foam considerably on shaking. The constituent responsible for the foam was not precipitable by mercuric chloride in the hot and was unaffected by a few minutes boiling with nitric acid or sodium hydroxide, but was decomposed by boiling for $\frac{1}{2}$ hr. with 3 per cent nitric acid. It did not pass through a dialysis membrane. The foaming constituent was precipitated from solution by the addition of ethanol to a concentration of 70 per cent at pH 4. After centrifuging off, the ethanol precipitate was redissolved in water to give a solution which foamed on shaking, indicating that the compound was not denatured by the alcohol precipitation. These results suggested that the constituent was carbohydrate in nature. The ethanol-precipitated material was hydrolysed for 4 hr. with 3 per cent nitric acid free from nitrogen peroxide containing a crystal of urea and the neutralized hydrolysate chromatographed on filter paper. The main constituents were the sugars normally found in the pectin and hemicellulose fractions of plants.

In each of the three experiments it was found, by using an accurate empirical laboratory method, that maximum foaminess occurs in the rumen 1–2 hr. after the cow began eating clover or lucerne, and fell away 4 hr. later to the pre-feeding level; the rumen contents of these cows were more foamy at all times than the contents from any cow eating grass or winter rations. This observation suggested that the foaming constituent appeared in solution in the rumen liquor after the plant had been physically broken down, and that it later disappeared, probably by the degrading action of the micro-organisms.

The whole picture of the fermentation, in the rumen of a cow eating clover or lucerne, is of a rapid reaction, as indicated by the high volatile fatty acid and ammonia nitrogen concentrations with copious gas production, the latter being entrapped in small bubbles in the rumen liquor owing to the presence of the pectins and/or hemicelluloses. It is important to note that under these feeding conditions, both the requirements for foaming to occur, namely, high gas production and the presence of a surface-active agent, are satisfied together and bloating may therefore occur. Each factor occurring on its own in this or any other situation may have no detrimental effect on the animal. The postulation that plant pectins and hemicelluloses are the substances responsible for the formation of a foam in the rumen of bloating cows does not preclude absolutely that other factors may be involved.

I wish to thank Dr. G. S. Pope for assistance with the chemical tests on some samples of rumen liquor.

PLANT PHYSIOLOGY

Effects of Auxins on Membrane Permeability and Pectic Substances in Bean Endocarp

It has been shown[1,2] that auxins delay the onset of senescence in bean endocarp and various leaf tissues (*Rhoeo*, *Mesembryanthemum*) maintained *in vitro*. In the absence of auxin, liquid-logging of intercellular spaces is followed by cellular dissociation and rounding off of cells. Similar changes have been observed in the abscission zones of *Coleus*, *Cestrum* and *Fuchsia*. When de-seeded bean pod segments are maintained in Petri dishes on wet filter paper, liquid-logging is evident in 2½–3 days and an exudate appears on the upper tissue surfaces. Cellular dissociation is usually complete by the fifth day. These changes are essentially prevented by the addition of an auxin (3-indoleacetic acid or α-naphthaleneacetic acid) to the culture medium. There are no significant differences in increase in fresh weight or respiratory activity between water- and auxin-treated endocarp segments over a ten-day period. The cells of liquid-logged segments are still capable of plasmolysis and deplasmolysis. The results indicate that the liquid-logging and exudation are manifestations of changes in permeability. A second process involves changes in the composition of the cell-wall cementing substances which take place in the absence of auxin and give rise to cellular dissociation and rounding off of cells.

Previous studies[3-6] have implicated pectin methylesterase as one of the enzymes directly affected by auxins. For pectin methylesterase, auxin appears to act through an adsorption–desorption mechanism which controls the activity of the enzyme in the tissue.

The results presented herein concern the nature of the permeability changes and the role of pectic enzymes in the processes causing cellular dissociation. Bean segments were prepared as before[2], and the exudate from water-treated segments collected for analysis. On addition of 3 vol. of ethanol, a precipitate was formed which was collected by centrifugation. The precipitate was dissolved in alkali, reprecipitated by acidification, and digested with a commercial pectinase preparation. The only substance detected in the digest was galacturonic acid. Analysis of ethanol-soluble substances in the exudate showed the presence of amino-acids, traces of organic acids and a large amount of a non-reducing sugar, which was identified as sucrose by paper chromatographic methods as well as identification of the hydrolytic products. Quantitative determination of the sucrose in the earliest-obtainable exudate gave a figure of $0 \cdot 029\ M$. The osmotic pressure of the same exudate was found to be $0 \cdot 050\ M$, thereby showing that sucrose is the major osmotic constituent. Ash analyses indicated that inorganic ions contribute much of the osmotic pressure not accounted for by sucrose. Since the exudate is continuous with the liquid in the free space of the tissue, there are large amounts of solutes, including soluble pectic substances, in the walls of exuding segments. The presence of sucrose in the exudate indicates an increase in permeability as sucrose is not a hydrolytic product of wall polysaccharides.

The nature of the permeability changes was further investigated by measuring the apparent osmotic volume of the tissue with respect to sucrose, and relating these changes to the liquid-logging and exudation occurring in segments maintained in the absence of auxin. The apparent osmotic volume was measured by the method of Briggs *et al.*[7]. In this measurement permeability changes are indicated by a large decrease in the apparent osmotic volume of the tissue with respect to the solute used for the determination. The results for two different batches of beans show that the time at which the osmotic volume of water-treated segments commences to fall rapidly is correlated with the onset of liquid-logging and exudation, and that all these changes are markedly reduced or prevented by the addition of auxin to the medium.

The similarity of the microscopically observable sequence of events which occur in abscission zones of certain plants and in bean endocarp segments, coupled with the fact that auxin alters these events in a similar way, presented the opportunity to test a hypothesis[8] which purports to explain the auxin-controlled changes occurring in the cell-wall cementing substances of abscission zones. This hypothesis invoked the combined action of pectin methylesterase and endopolygalacturonase. The latter enzyme has been shown to act much more rapidly on de-esterified pectins, and an increased reaction-rate is therefore a natural consequence of the presence of an active esterase. It was proposed that the solubilization of pectic substances in abscission zones could be brought about by desorption (activation) of pectin methylesterase at low levels of auxin. If the hypothesis is correct and the auxin-controlled processes of abscission zones and bean endocarp are indeed analogous, it follows that pectin methylesterase should be present in the exudate from water-treated endocarp segments. Assays were carried out using a manometric technique described previously[5] and the presence of the enzyme in the exudate established. The actual amount of enzyme increased in an approximately linear manner over the 4-day period.

In further support of the above hypothesis explaining solubilization of pectic substances, evidence has been obtained for the presence of a polygalacturonase-like enzyme capable of reducing the molecular size of pectic acid. The occurrence of this enzyme has been reported only in a few instances in higher plants (tomato[9], avocado[10], pear[11]). Viscosity measurements were carried out on pectic acid solutions using either tissue slices or a cell-free extract as the enzyme source and with appropriate controls. Significant reductions in viscosity were measured in both cases.

These results show that a low level of auxin in bean endocarp gives rise to permeability changes and to alterations in pectin metabolism which are correlated with liquid-logging, surface exudation and cellular dissociation. The results suggest that the action of auxin may be a surface phenomenon affecting the physico-chemical characteristics of cellular membranes and interfaces as previously proposed by Veldstra and Booij[12]. Two of the manifestations of this effect would be changes in membrane permeability and changes in the amount of pectin methylesterase adsorbed at cellular interfaces. Full details of this work will be published elsewhere.

Carbohydrate Constituents of the Mycelium of *Penicillium chrysogenum* grown in Media with Different Sources of Carbon

THERE are several reports on the carbohydrate constituents of the mycelium of different strains of *Penicillium chrysogenum* grown under different conditions. The presence of mannitol, erythritol, a polysaccharide containing glucose, mannose and galactose[1], pentosan[2], phosphates of mannose, and inositol[3] and of glucose, fructose, pentose and heptose[4] have been reported. Shu and Thorn[5] grew *P. chrysogenum* *Q*176 in Czapek–Dox medium with 5 per cent glucose, galactose and xylose individually as the sole carbon source and reported that the mycelial hydrolysate in each case consisted of glucose.

We have grown *P. chrysogenum* (strains *HA*-6 and *HA*-9, used in production here) in shake flasks in the synthetic medium of Gitterman and Knight[6] with 2 per cent sucrose, lactose, glucose, galactose, fructose, L-sorbose, mannitol, *myo*-inositol, *myo*-inosose-2, glucuronolactone, ribose, xylose, L-arabinose, glycerol and sodium acetate as the sole carbon sources. The inoculum was the centrifuged and re-suspended 'seed mycelium' (used for inoculating the big fermentors) grown in the 'seed tanks' of the plant in corn-steep–sucrose medium with aeration and agitation for 48 hr. after inoculation with spores. When the carbohydrate in the medium was almost exhausted (3–8 days), the cells were collected, washed with water and dried. In addition, three samples of 'seed mycelia' (S_1, S_2, S_3) and three samples collected from the fermentors (*F*-1374, *F*-2380 and *F*-2382) at the end of fermentation (98–110 hr.) were also taken up for comparative study.

The dry, well-powdered mycelium (100 mgm.) was extracted three times with ether, three times with *iso*propyl alcohol (which removed mannitol), and then three times with cold water to give a total of 10 ml. of the cold-water extract (*A*). The residual mycelium was treated with 1 ml. of 80 per cent

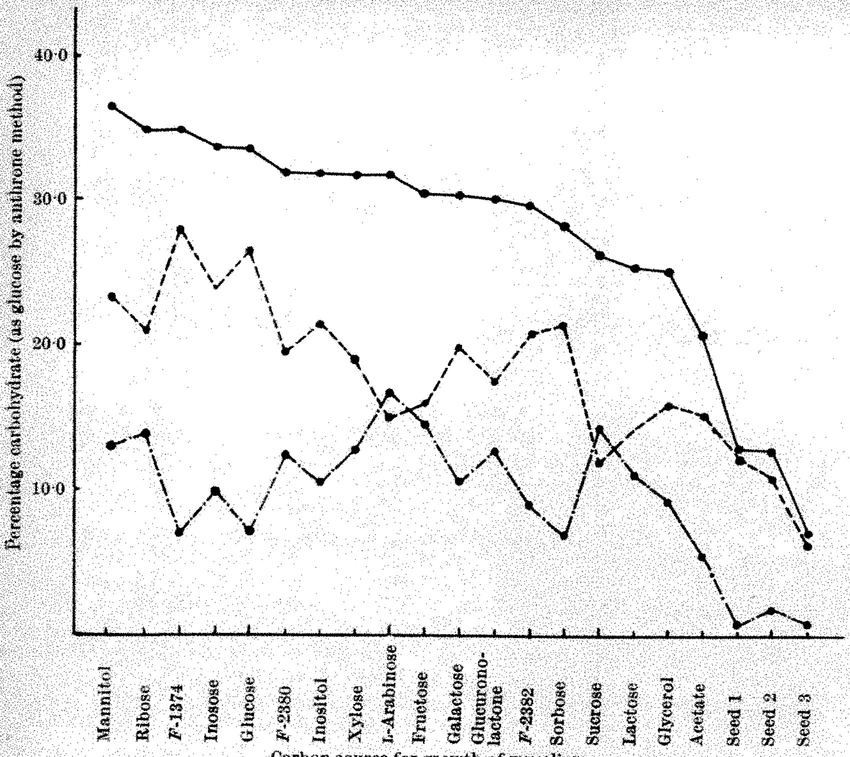

Fig. 1. The carbohydrate content of the aqueous extract (*A*), the polysaccharide (*B*), and total carbohydrate (*A* + *B*) as estimated by anthrone method and expressed in terms of glucose. The samples are arranged in the descending order of total carbohydrate content. —·—·, *A* ; – – – –, *B* ; ———, *A* + *B*

sulphuric acid, allowed to stand for about 2 hr. for solution and then diluted to 10 ml. The insoluble material (probably chitin) which separated was filtered off, and the filtrate (*B*) heated on a boiling water-bath for 3 hr. to give the hydrolysate (*C*). The carbohydrate content of (*A*) was assayed by the anthrone[7], Somogyi[8] and periodate[9] methods (to detect the relative amounts of polysaccharides, reducing sugars and sugar alcohols), of (*B*) by the anthrone method (to estimate the polysaccharides) and of (*C*) by the Somogyi method. The results obtained are presented graphically in Fig. 1.

The aqueous extracts and neutralized hydrolysates were passed through 'Dowex 50' (H⁺) and analysed for sugars by the spectra with unsulphonated and presulphonated resorcinol according to the method of Devor, Conger and Gill[10] and by descending paper chromatography on Whatman No. 1 paper, using 80 per cent *iso*propyl alcohol as the solvent and silver nitrate, aniline phthalate and phloroglucinol as dip reagents. For confirmation, water eluates of the paper strips cut out from the chromatogram corresponding to the various spots were analysed by the resorcinol spectra[10]. The results obtained and the points of interest that emerge from these studies are as follows :

(1) *Total carbohydrates* (*A* + *B*). This varies from 20·6 to 36·5 per cent, depending upon the nature of the sugar used, with no correlation being apparent between this percentage and the structure of the sugars.

(2) *Water extract* (*A*). This accounts for 20–52 per cent of the total carbohydrates in the various samples. The component sugars seem to be almost the same in all the samples, though there are quantitative differences. Glucose accounted for about 90 per cent of the total, probably with traces of galactose. Chromatography revealed five more carbohydrates—ribose, three disaccharides giving glucose on hydrolysis, one of which is most probably trehalose, and one with R_G 140 which does not appear to be glucuronolactone.

(3) *Hydrolysates* (*C*). All the samples were found to consist of the same sugars. Glucose was again the predominant sugar with perhaps traces of galactose. In addition, there were a sugar with R_G 50 which is not inositol, the compound with R_G 140, and a compound with R_G 110 which is not fructose or sedoheptulose and gives a complex resorcinol spectrum. Ribose was not detected. There is an inverse correlation between the percentage of the sugar content in the aqueous extract (*A*) and the hydrolysate (*C*), the significance of which is not clear at the moment.

(4) *Seed Mycelia*. These stand out as a class by themselves. The total carbohydrate content and also the percentage of the sugar in the aqueous extracts are low. The aqueous extract consisted of fructose, ribose, a small quantity of glucose, traces of trehalose and the sugar with R_G 140. On hydrolysis of this aqueous extract with *N* sulphuric acid for 30 min., the sugar content apparently increased two- to three-fold, and galactose appeared as the predominant sugar in the hydrolysate. The hydrolysate of the water-extracted residual mycelium was found to be of the same pattern as the hydrolysates (*C*) of the other mycelia, except that ribose was also detected here.

P. chrysogenum can utilize a variety of sugars and carbon sources for growth, though the degree of growth varies. It is striking that, irrespective of the nature of the sugar or the carbon source used in the medium, the component sugars in the aqueous extract (*A*) and the hydrolysate (*C*) remain the same, glucose being most predominant. There exists, therefore, a mechanism for the conversion of all the sugars and carbon sources first into glucose, which afterwards becomes converted into the polysaccharide. To elucidate these metabolic pathways, we are analysing the culture fluids for intermediates in the growth experiments with the various sugars. The concentration of sugars in the 'free sugar pool' of the aqueous extract would be the resultant of the quantity of the sugars synthesized from the media component and the drain by the conversion into the polysaccharides. It could be expected that, when the rate of growth of the mycelium is low with little demand from the 'free sugar pool', there would be an accumulation of these sugars in the pool and vice versa. The latter situation seems to be prevailing in the fast multiplying seed mycelia. The difference we have noticed between the 'seed mycelia' and the full-grown one in the fermentors probably explains why the former produces no penicillin at all while the latter does[11]. The presence of free glucose and ribose and also the large percentage of sugars in the 'free sugar pool' of the aqueous extracts is of interest. Whether the sugars exist as such or are produced during the processes of extraction is being studied. The free ribose detected need not be a degradation product of nucleic acids, but could be the excess produced over what is diverted for the synthesis of the nucleotides and also used up for conversion into glucose.

Full details will be published elsewhere.

Control of Superficial Scald in Stored Apples

Although superficial scald of apples is effectively controlled by wrapping in paper impregnated with mineral oil the labour involved in doing so renders the method expensive, and the search for alternative methods of control continues. Fidler[1] has shown that the view that superficial scald is attributable to an injury to the tissues caused by volatile products of the metabolism of the fruit fails to explain many of the observed phenomena. He has suggested that an interaction between a heavy volatile substance *Y* which cannot be removed from proximity to the fruit by ventilation and a non-volatile substance *X* produces a compound or compounds toxic to the skin. Recent observations made during the course of experiments on the control of low-temperature injury would seem to support Fidler's view.

Apples of the variety Bramley's Seedling were picked from twelve large trees at three different dates. Comparable samples were made up within each harvest and were stored on trays in air at 0° C. Four trays from each harvest were placed at 15·5° C. for 5 days commencing with the date of picking and afterwards at intervals until the thirtieth week. Up to the twelfth week the warming was applied at fortnightly intervals. No tray of fruit was subjected to warming more than once.

Fig. 1 shows the percentage of fruits affected in the second harvest after 34 weeks from the date of storing. The relationship shown is characteristic also of that obtained with the two other harvests, although the amount of scald in the last pick was small, as is usual with fruit of more advanced maturity. There was a progressive reduction in the percentage of apples with superficial scald and a diminution of severity with warming at successive intervals of time from the second to the twelfth week and a complete absence of scald when the apples were warmed at the sixteenth and twentieth weeks. Scald was very marked on the fruit treated at the thirtieth week. It has hitherto been considered that the damage to the fruit, although it does not become manifest until later, is incurred before the sixth–eighth week after putting into store[2]. These results suggest that this is not necessarily so.

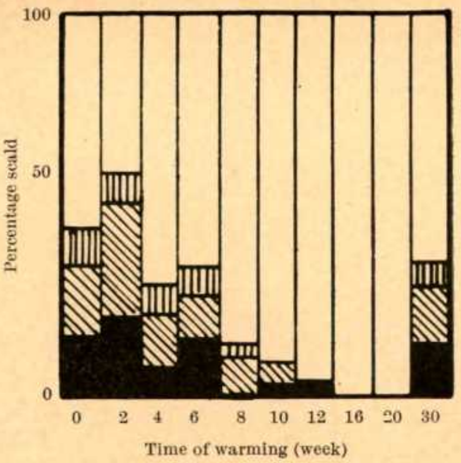

Fig. 1. Effect on the occurrence of superficial scald of keeping Bramley's Seedling apples for 5 days at 15·5° C. at successive stages during storage at 0° C. Vertical hatching, slight scald; oblique hatching, moderate scald; black, severe scald

Kidd and West[3] observed that very brief intermittent warming of Newton Wonder apples during storage at 3° C. reduced the amount of scald. Treatment, however, commenced early in the storage life and was continued throughout the period.

A possible explanation of the result described above is that the combination of substances *X* and *Y* is cumulative and reversible at higher temperatures, so that when warming is carried out prior either to the build-up of a sufficient concentration of the toxic substance or before the substance has had time to react lethally upon the cells, no scald injury results. If, however, the time-interval exceeds a certain limit, scald will appear in an amount increasing with extension beyond this limit. Although in Fig. 1 no observations are recorded for warming at intervals between the twentieth and thirtieth week, it can safely be assumed that, had they been made, an upward gradation in the amount of scald would have appeared in this interval.

From the practical point of view change of temperature would seem to be a possible method for control of superficial scald provided the fruit could be stored at 0° C. without low-temperature injury or provided the same effect could be secured at a temperature of storage above the critical level for low-temperature injury.

BIOLOGY

The Possibility of distinguishing between Substances shown on Electron Micrographs

THE electron microscope can be used to investigate the morphological features of a specimen right down to the molecular level, but there is as yet no way of identifying the chemical nature of the substances seen, except on the rare occasions when these happen to be crystalline. In a specimen of uniform thickness, a region of high electron opacity may, in general, be said to be one containing substances of a greater weight density than those of the surrounding less opaque region[1], but this gives little help in deciding on their chemical composition. The lack of any direct way of knowing what substances one is looking at is perhaps the most serious shortcoming of electron microscopy.

It thus seems worth describing a simple way in which the image formed by an element of high atomic number differs from that of an element of low atomic number. Biological substances seldom vary significantly in the mean atomic number (calculated on a weight basis) of the elements composing them, but the method to be described can be used, for example, to identify which parts of a specimen have taken up an added 'stain' of high atomic number.

It is well known that the contrast between the different features of a biological specimen can be increased by reducing the size of the objective-lens aperture. This observation is in good accord with the theory of electron scattering deduced from considerations of quantum mechanics[2,3]. Hall and Inoue[4], for example, found that when the angular aperture of the objective was reduced from $4 \cdot 2 \times 10^{-3}$ to $2 \cdot 1 \times 10^{-3}$ radian, the scattering cross-section of polystyrene latex increased by 30 per cent. Lenz's theory[2,3] predicts an increase of about 25 per cent. But with an element of high atomic number, theory suggests that the size of the aperture will have little effect on contrast. I have made observations which in fact confirm this; for, unlike carbon, films of gold, platinum and tungsten show no detectable change in opacity when the objective aperture is changed for one of half the size.

The method of differentiating substances of high atomic number from biological or other material of low atomic number thus consists simply of taking two electron micrographs of the same field using a different-sized aperture for each. With many microscopes, changing the aperture involves only a simple manipulation that does not even require the beam to be switched off. The two plates are similarly exposed and developed. All substances with a mean atomic number (Z) less than 12 should show an image of markedly different density on the two plates. Two conditions, however, must be satisfied for this change to be seen. First, the image of any object under test must be considerably less dense than the background of supporting film (that is, the object must have a sufficient electron opacity): secondly, the plates must be exposed for long enough to give this image an optical density of about $0 \cdot 5$ or more (that is, distinctly darker than an unexposed part of the plate). If these conditions have been satisfied, then an object showing no change in opacity may be safely identified as one containing a large content of material with an atomic number greater than 20.

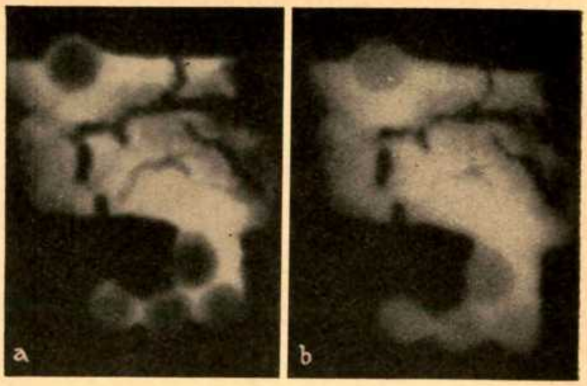

Fig. 1. Electron micrographs of polystyrene latex spheres surrounded by phosphotungstic acid (× 45,000); (*a*) using an objective aperture of 10^{-2} radian; (*b*) using an objective aperture of 5×10^{-3} radian

As an example of the method, Fig. 1*a* shows an electron micrograph of some polystyrene latex spheres surrounded by a dried-down mass of phosphotungstic acid. The latex spheres were less opaque than the phosphotungstic acid and can be clearly distinguished. A second plate was exposed of this same field but using an objective aperture of half the size. The plate was reproduced in exactly the same way and is shown in Fig. 1*b*. (Both figures are printed as negatives, that is, as the original plates.) The latex particles are now almost indistinguishable from the surrounding material, the polystyrene latex (mean $Z = 5 \cdot 6$) having gained considerably in opacity while the phosphotungstic acid (mean $Z = 58$) did not. The demonstration is made more vivid if the plate shown in Fig. 1*a* is projected in red light and the image superimposed on that of Fig. 1*b* projected in green light. The objects of low atomic number then appear green against the material of high atomic number, which looks yellow.

A full mathematical treatment of this topic will be given elsewhere, but it seems that a quantitative application of the method would allow one to differentiate calcium ($Z = 20$) or even phosphorus ($Z = 15$) from, say, protein (mean $Z = 7$). It would not, however, be possible to distinguish between the chief biological materials, proteins, carbohydrates, lipids and nucleic acids in this way, or to distinguish between any of the higher elements ($Z > 25$).

Enzymic Hydrolysis of Fucoidin by *Pseudomonas atlantica* and *Pseudomonas carrageenovora*

FUCOIDIN, a common polysaccharide sulphate in brown seaweeds, has been shown by methylation[1,2] and acetolysis[3] to consist of a chain of L-fucopyranose units joined in α-glycosidic linkages through carbon atoms 1 and 2 of adjacent units, each unit being sulphated on carbon atom 4. The results obtained from methylation studies also indicate that 1 : 3 and 1 : 4 linkages are present. A fucoidinase would greatly assist further studies on the structure of fucoidin. The object of this communication is to report the discovery of such an enzyme obtainable from two species of marine bacteria.

Fucoidin was prepared from *Fucus vesiculosus* by extraction with hot water[4]. Bacterial cultures were taken from a private collection of marine bacteria which had been used for degradative studies of agar and carrageenin. They had been isolated from seawater and marine algae in the neighbourhood of Halifax, Nova Scotia. *Pseudomonas atlantica*[5] hydrolysed agar and a Gram-negative rod hydrolysed carrageenin[6]. The latter was afterwards shown to have a polar flagellum and is now named *Pseudomonas carrageenovora* n.sp.

The micro-organisms were grown for 72 hr. at 20° C. on a rotary shaker in a medium which contained sodium chloride, 30·0 gm.; dipotassium hydrogen phosphate, 1·0 gm.; crystalline magnesium sulphate, 0·5 gm.; sodium nitrate, 0·5 gm.; ferric chloride (1 ml. of a 2·0 per cent solution); fucoidin, 2·5 gm./l. of distilled water.

The utilization of fucoidin by the marine bacteria was determined from the fucose equivalents of aliquots removed from the control and fermentation flasks. The fucose equivalent of fucoidin was obtained by hydrolysing an aliquot of the medium with 0·5 *N* hydrochloric acid in a sealed tube for 18 hr. in a steam-bath. The hydrolysate was cooled, neutralized and the concentration of fucose determined by the method of Somogyi[7] with fucose as standard. The amount of fucoidin utilized by *P. atlantica* was 31·5 per cent and by *P. carrageenovora* 29·9 per cent.

The cell-free medium was used as the enzyme solution. One volume of enzyme solution was added to two volumes of 0·9 per cent solution of fucoidin in 0·2 molar phosphate buffer. Aliquots were removed at intervals, and the increase in reducing power, expressed as fucose, was determined by Somogyi's method[7].

The relationship between *p*H and enzyme activity is shown in Fig. 1. The enzyme activity was greatest around *p*H 7·0. After 24 hr. at 40° C. and *p*H 7·0 the apparent degree of conversion of fucoidin to fucose by enzmye preparations from *P. atlantica* and *P. carrageenovora*, was respectively 24·2 per cent and 15·9 per cent (Table 1).

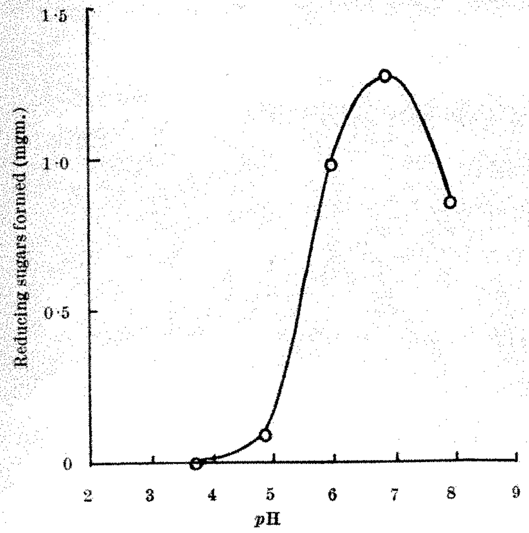

Fig. 1. The relationship between *p*H and enzyme activity. Reducing sugar as fucose after 3 hr. at 40° C. Enzyme solution from *Pseudomonas atlantica*

Table 1. ENZYMIC HYDROLYSIS OF FUCOIDIN

Enzyme from	Fucose (mgm.)		Hydrolysis of fucoidin (per cent)	
	3 hr.	24 hr.	3 hr.	24 hr.
P. atlantica	1·07	2·10	12·3	24·2
P. carrageenovora	1 19	1·39	13·7	15·9
*P. atlantica**	—	0·81	—	8·9

* Enzyme solution heated for 10 min. at 100° C.

The enzyme solution was heated for 10 min. at 100° C. and then added to the fucoidin. Results in Table 1 show an 8·1 per cent hydrolysis of fucoidin in the cell-free mixture. A similar effect was noted in previous experiments with a *K*-carrageenase. Further studies are planned on the purification of the enzyme and identification of the hydrolytic products.

Marlins in British East African Waters

THE first confirmed report of the striped marlin (*Makaira audax*) in the Indian Ocean was that of Smith[1], who recorded details of a 160-lb. specimen of 89 in. (2,260 mm.) standard length from Mossel Bay, South Africa. Morrow[2] reported having seen the striped marlin off Pemba Island and Mombasa in 1950; but no specimens were caught or examined. Copley[3] records a so-called striped marlin taken by him off Mombasa in 1934 (weight, 127 lb.) but does not mention the striped marlin at all in his "Game Fishes of Africa"[4].

I agree with Smith[1,5] that the name *M. audax* Phillipi 1887 for the striped marlin has priority over *M. mitsukurii* (Jordan and Synder) 1901 used by LaMonte[6] and most American workers prior to that publication. LaMonte hoped that a change in the law of priority under "The Rules" would allow *M. mitsukurii* to stand, but this was not so. *M. audax* has been used by later American workers, such as Royce[7] in his paper on the Central Pacific spearfishes, although Morrow[8] still retains the name *M. mitsukurii* in discussing races of the striped marlin in the Pacific.

During recent cruises of the *Manihine* (the research vessel of the East African Marine Fisheries Research Organization) during October–December 1958, a deep long-line was used for the capture of yellow-fin tuna (*N. macropterus*) and among the catch were 15 striped marlin—a further seven were lost while hauling. Catches were made between Malindi, Kenya (3° 20′ S.), and Mafia Island, Tanganyika Territory

Table 1. LENGTH AND WEIGHT OF *M. audax* IN EAST AFRICAN WATERS

	1954	1958														
Total length (mm.)	2,590	2,200	2,530	2,485	2,515	2,580	2,480	2,700	2,590	2,770	2,560	2,650	2,800	2,735	2,760	2,830
Standard length (mm.)	2,250	1,860	2,150	2,185	2,160	2,210	2,125	2,300	2,250	2,325	2,180	2,360	2,510	2,360	2,450	2,395
Weight (lb.)	115	75	105	115	120	127	130	130	135	145	148	150	160	165	185	190

(8° S.), 10–20 miles offshore. It would seem, therefore, that striped marlin are not so rare in these waters, at least during the last three months of the year, as records, or the lack of them, would suggest. A marlin taken by trolling on October 5, 1954 (at 7° 35′ S., 39° 54′ E.), and recorded in the annual report of this Organization for 1955–56 [9], as *Tetapterus brevistoris* Playfair was, from the details, undoubtedly a striped marlin. In Table 1, total and standard length in mm. and weight in lb. are given for East African specimens of *M. audax* taken so far.

Certain proportions for the East African specimens are compared with those for LaMonte's Pacific specimens and that of Smith from South Africa in Table 2.

Table 2. COMPARISON OF *M. audax* FROM THE PACIFIC OCEAN AND SOUTH AND EAST AFRICAN WATERS

	LaMonte Pacific specimens. Range	Smith South African specimen	East African specimens. Range
Head in standard length	2·46–2·72	2·61	2·64–3·02
Depth in standard length	5·4–6·58	6·59	5·70–7·03
Depth in pectoral length	1·0–1·8	1·53	1·16–1·43
Height of dorsal lobe in depth	= or less than 1	0·75	0·78–0·97
Height of dorsal lobe in pectoral length	1–1·3	1·15	1·04–1·34

East African striped marlin are brilliantly coloured —cobalt blue above and white below on the belly; the number of pale lavender coloured stripes varies considerably. On death, the fish becomes a uniform slate-grey above and pale below; the pale stripes persist after death for some time, but after refrigeration for a few days the stripes may be lost altogether.

It is interesting to note that no other species of marlin has been taken by this Organization (1951–to date) or seen by us in the fish markets of East Africa. It seems probable, however, that the black marlin is also present in these waters, although the records are somewhat dubious. Morrow[2] records a black marlin (*M. nigricans marlina*) from Pemba of 259 lb. and 2,151 mm. standard length, although Smith[5] points out that this is approximately 100 lb. greater than the average weight at that length. Similarly, Copley[10] records a so-called black marlin taken off the Kenya coast of 360 lb. at 3,365 mm. standard length, considerably less than the average for a black marlin of that size. *Histiophorus brevistoris* Playfair, said by Smith[5] to be the black marlin, is, I think, to be more correctly treated as *species indeterminata*, as did LaMonte[6], although Playfair's fish does possess more features like the black marlin than the striped. Playfair's type from Zanzibar was destroyed; the only species of marlin seen in Zanzibar markets in the past eight years has been *M. audax*.

Further details on the biology of the striped marlin will be given at a later date when the whole problem of long-lining off the East African coast will be discussed.

I must point out that *Marlina jauffreti* Smith 1956 [5], from Mauritius, was named purely on the details of a marlin visible in a not very clear photograph and a few notes received by Smith. Although a new species of marlin may be present in Mauritius waters, the establishing of a new species of fish on the basis of a photograph and without access to the fish itself at a later date (it appears to have been destroyed) is likely to introduce confusion to the system of nomenclature and is to be deprecated, especially in such a closely related group as the marlins.

Development of Ovarial Teratomas in Viviparous Toothcarps by Pathological Parthenogenesis

RECENTLY, I described three cases of pathological parthenogenesis in viviparous toothcarps, in which the stimulus required for the development of the unfertilized oocytes consisted in a local infection with the *Ichthyophonus* parasite, the phycomycete *Ichthyophonus hoferi* Plehn-Mulsow[1].

As some years ago I had observed in a *Lebistes* female an ovarial teratoma which also showed a close relation with an *Ichthyophonus* process[2,3], I was under the impression that teratomas can develop parthenogenetically in the viviparous toothcarps as well. I therefore decided to continue the systematic examination of the virgin females, hoping in this way to make some contribution toward explaining the origin of teratomas in general.

In this investigation one ovarial teratoma was observed on 1,484 adult virgin females of *Lebistes reticulatus* as well as on 1,179 adult virgin females of *Xiphophorus maculatus*, whereas on 946 adult virgin females of *Xiphophorus helleri* no ovarial teratoma was present.

The *Lebistes* teratoma, which was present in a 41-mm. female, was composed of connective tissue, musculature, cartilage, bone, blood vessels and nervous tissue, whereas in the *Xiphophorus* teratoma, occurring in a 68-mm. female, also intestinal structures, glandular structures and cysts could be demonstrated.

In both cases an *Ichthyophonus* process was present in the ovaries and in their surroundings, of which the cysts varied in size and were localized in the cranial part as well as in the caudal part of the organ.

For microscopic confirmation of the virginity of the fishes, the sperm chambers of the ovaries were examined; no spermia were found. On the strength of this finding, self-fertilization—a phenomenon accidentally occurring in the viviparous toothcarps and explained by the presence of a bisexual gonad producing spermia and oocytes—could be excluded.

The coincidence of the ovarian teratoma on one hand, and the occurrence of the *Ichthyophonus* infection on the other, justifies the assumption that the development of a tumour is caused by the *Ichthyophonus* toxin, which provided the artificial stimulus for the parthenogenetic development of an unfertilized oocyte to teratoma. In this case the pathological process resulted in the parthenogenetic development.

It is not known why, in the cases formerly described, the local *Ichthyophonus* process caused a parthenogenetical development of the unfertilized oocytes and in other cases a pathological development to teratoma. In the latter cases, the damage to the unfertilized oocytes by the agent causing inflammation may have been such that normal embryological development was no longer possible.

It may be remarked that Spurway[4] did not mention the occurrence of teratomas in the virgin *Lebistes* females.

Ultrastructure of Pineal Eye Sensory Cells

WORK on the ultrastructure of photoreceptor elements in the lateral eyes of vertebrates[1-3] has advanced to the extent of becoming incorporated in a recent edition of a well-known text-book[4]. Ultrastructural research is also being done on invertebrate compound eyes[5,6]. So far as could be ascertained no work has yet been published on the ultrastructure of the eye-like pineal structures occurring in several vertebrate classes. For various reasons, such as compactness of pineal epithelia[7], small size of the structures involved[8] and bad preservation arising from fixation difficulties[9], there is considerable divergence of opinion and uncertainty regarding the nature and structure of the pineal sensory cells and their appendages as seen with the light microscope.

I have examined the ultrastructure of the inner and outer segments of the sensory cells in the adult pineal eye of the lizard *Cordylus polyzonus*. The structure of the appendages in this species has already been studied with the light microscope[10].

The material for the present study was fixed for 2 hr. in 1 per cent osmic acid buffered to *p*H 7·5 (veronal acetate) at 2° C. The fixation procedure previously employed[10] which involved injection of fixatives into, and their drainage from, the subdural cavity was abandoned in favour of, after paraldehyde anæsthesia, simply cutting out a flap of cranial roof containing the pineal eye and immersing this material in the fixative. This method, ensuring prope penetration, gave superior structural preservation The material was embedded in *n*-butyl methacrylate sectioned with a Porter–Blum ultramicrotome an studied under a Siemens electron microscope.

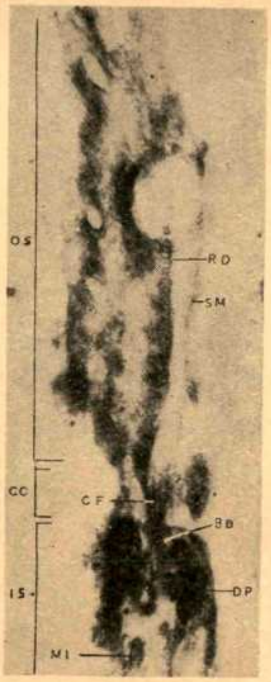

Fig. 1. Electron micrograph showing parts of the inner and outer segments of a sensory cell from the pineal eye of *Cordylus polyzonus*. The microstructure of these segments appears to be completely identical with that of the corresponding elements in the lateral eye. *BB*, basal body; *CC*, connecting cilium; *CF*, ciliary fibril; *DP*, dense particles; *IS*, inner segment of sensory cell; *MI*, mitochondria; *OS*, outer segment of sensory cell; *RD*, rod disks; *SM*, surface membrane. (× 16,000)

The results obtained indicate that, among possibl more than one type of sensory cell in the pineal eye there are sensory cells with inner and outer segment almost completely comparable in structure to th same elements in the vertebrate lateral eye. Thu the inner segment (projecting into the pineal ey lumen) contains mitochondria, dense particles and basal body in which a connecting cilium terminates This latter connects the inner segment to the oute segment, and is composed of a so far unknown number of ciliary fibrils, no cross-sections through th connecting cilium being available yet. Some of thes ciliary fibrils show up clearly, however, in Fig. 1 illustrating a longitudinal section through part of sensory cell. In the outer segment the surfac membrane and so-called rod disks are clearly recognizable, and appear to be identical with their counterparts in the rods of the vertebrate lateral eye. I view of the great similarity in the structure of th photoreceptory cells wherever they occur in th animal kingdom (that is, in lateral eyes of vertebrates in the compound eyes of insects and arachnids), th conclusion would seem to be justified that the cell of the pineal eye possessing a microstructure of th same type are actually photoreceptory cells. Furthe investigations on this subject are in progress.

I should like to record my appreciation of th interest shown in this work by Prof. B. I. Balinsky who gave me facilities for this work, and to than Miss A. de Kock and Mr. J. W. Matthews for skille technical assistance. I wish also to thank Dr. A. Brink and Mr. J. W. Kitching for their aid in connexion with material.

The work is supported by a grant from the South African Council for Scientific and Industrial Research.

Delayed Denervation and Accessory Limb Formation in Urodeles

FROG kidney adenocarcinoma implants and normal adult frog kidney implants made subcutaneously on the dorsal radioulnar surface of non-regenerating larval salamander forelimbs cause the host limbs to respond to their presence by forming supernumerary hand-wrist structures. Larval host limbs may on occasion fail to elicit any morphological response[1]. On the other hand, adult salamander host limbs may form: (*a*) an accessory structure comparable with the larval response; (*b*) nothing; (*c*) single or clustered subcutaneous cartilaginous nodules as in Fig. 1 [2,3]. Although these nodules are commonly found in adult host limbs, they had never been produced by larvæ in hundreds of cases assayed.

Serial denervation of larval host limbs, by resection of brachial plexi, begun at 4 days post-implantation, will prevent the production of supernumerary structures[4]. The necessity of innervation for amphibian limb regeneration is well known[5], and in this case the trauma of foreign implant material did not act as a substitute for the influence of the nerve.

The experiments reported here entail denervations of brachial plexi of host limbs, which were delayed 12, 13, 14, 16 and 19 days post-cancer implantation, in 14 larval *Taricha granulosa* and 15 larval *Amblystoma opacum*. The technique has been reported previously in detail[4]. No supernumeraries were recovered in the 12-, 13- and 14-day groups, although three were obtained from the 16- and 19-day groups. The significance of the results is not simply that delayed denervation effects supernumerary development but is in the fact that 5 cases of cartilage nodule formation were obtained in these larval limbs.

These results with the larvæ suggest some ideas regarding this process. They indicate that delayed withdrawal of innervation may be tantamount to removing the growth stimulus to the blastemal mesenchymal cells, cells which are chondrogenically oriented with respect to their developmental potential[6] and, as a consequence of withdrawal of the growth stimulus, these aggregations differentiate into cartilaginous nodules. The common occurrence of nodules in adult host limbs might similarly be explained by co-ordinating certain assumptions and experimental facts to bring about 'theoretical delayed denervations'. The assumptions represent equal and opposite alternatives, and are as follows: (*a*) the terminal innervation pattern of adult urodele limbs may be reduced from the larval condition; a possible extrapolation of the results of Van Stone[7,8], or (*b*) the terminal innervation threshold necessary to support regeneration may be higher in adult than larval limbs, see Singer[5]. Each would have the effect of making it more difficult to obtain innervation sufficient to support accessory morphogenesis in adult host limbs.

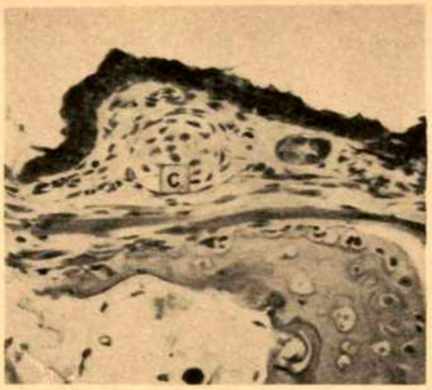

Fig. 1. Longitudinal section of an adult *Triturus viridescens* host limb bearing a subcutaneous accessory cartilage nodule *c*, which was induced to form by a frog kidney adenocarcinoma implant. (× *c*. 120)

Although implant trauma may aid in bringing about dissociation of soft mesodermal host limb tissues to establish a mesenchymal population, these cells will only undergo accumulation into a blastema under the influence of innervation. If the innervation continues to be adequate to support growth and morphogenesis, then a supernumerary will result. If, however, it becomes reduced, subsequent to accumulation and some growth, nodule formation will be obtained.

How, then, can we account for this type of neural reduction in adult host limbs? It seems likely that the implant-induced situation may share with the amputated regenerating limb the possession of a temporarily increased terminal nerve supply[5], and in adult host limbs we have two factors which could combine to bring about a premature return to the normal adult-level. First of all, we know that due to an increased foreign body response in adult Amphibia, the implant will be destroyed more rapidly in adult limbs than in larvæ. Secondly, we know that blastemal formative processes, and indeed all morphogenetic processes, of adult limbs are considerably slower than these same processes during larval limb regeneration. Thus the combination of a more rapid disappearance or at least reduction of the traumatic stimulus and slower blastemal and morphogenetic events could easily account for a premature return to normal innervation patterns with nodules, rather than a supernumerary, the more usual end result.

Previously, I referred to the dissociation of soft, mesodermal tissues of the host limb to provide cells for the future blastema. This statement should be clarified by pointing out that it is usual in implant-induced accessory limb formation that the skeleton of the supernumerary does not articulate with or grow out from the 'mother' limb skeleton. If, however, the traumatic influence bringing about the dissociation of host tissues reaches the skeletal region, then articulation and even some perichondrial outgrowth will be established. (The separateness of perichondrial growth and nodule formation has been clearly pointed out in an experiment by one of my students, J. Andrew Armer. Deviated, cut brachial nerves of the upper forearm of adult *Taricha granulosa* are capable of inducing, in distinct fashion, humeral perichondrial growth *and* nodule formation in soft tissue regions. It should be noted, lest this appear to be contradictory to the thesis of the preceding, that in these instances little or no nerve *growth* could be discerned by silver stain techniques, indicating low-level innervation.) The implant-induced situation might be likened to the regeneration of amputated dehumerized limbs in that the skeleton of the accessory structure usually forms without the aid of adjacent stump or host limb skeleton. The nodules, which now may be considered as having been formed as the result of abortive attempts at supernumerary formation, follow the same pattern in the sense that they appear anatomically separated from the 'mother' limb skeleton.

These investigations were supported in part by a research grant (*C*–2913) from the Research Grants and Fellowships Branch, National Cancer Institute, National Institutes of Health, Bethesda, Maryland.

Induction of Subcutaneous Nodules in Rabbits with the *SE* Polyoma Virus

THE *SE* polyoma virus grown in mouse embryo cell cultures is capable of inducing a wide spectrum of histologically different neoplasms in hybrid $(C_3Hf \times AKR)F_1$[1] and randomly bred Swiss mice[2], and sarcomas and angiomatous lesions in hamsters[3], and rats[4], if injections are made when the animals are new-born. Tumours in these animals increase in size and number and eventually kill the animals. Contrary to experience with these rodents, new-born rabbits of mongrel breed reacted by developing multiple subcutaneous nodules that later regressed.

The virus was propagated in mouse embryo cell cultures maintained with synthetic medium 199[5] containing 2 per cent horse serum heated to 56° C. for 30 min. The medium was replaced at weekly intervals and only fluid from cultures incubated with the virus for 14 or more days was used for transferring to new cultures or for inoculating animals.

Thirty-two mongrel rabbits less than one day old were injected subcutaneously in the nuchal area with 1 ml. each of undiluted tissue-culture-grown virus of five different sub-lines[6]. 13–64 days later, 19 of the rabbits developed subcutaneous nodules—an incidence of 59 per cent. Most of the nodules were discrete, small and hard; some were large and filled with reddish or amber-coloured fluid. From the largest of such nodules 11 ml. of fluid was removed (Fig. 1).

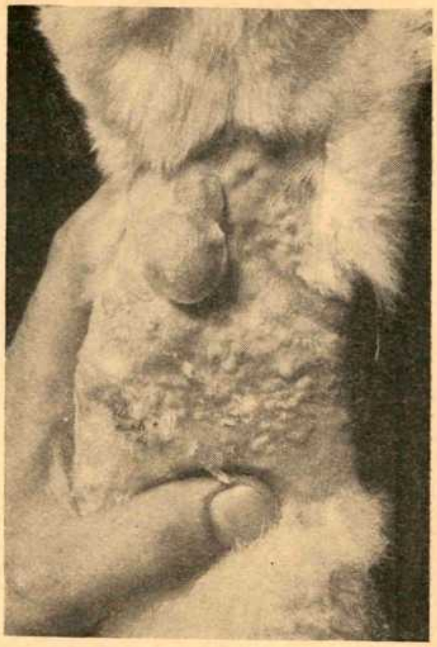

Fig. 1. Multiple subcutaneous nodules induced in a rabbit 56 days of age by injection with *SE* polyoma virus when new-born

A nodule from a rabbit 56 days of age was minced and added to mouse embryo cell cultures and these cultures were maintained and fluid passed to new cell cultures, as has been described[1–4]. New-born hamsters, inoculated with 0·2 ml. each of fluid from second tissue-culture passage of this material, developed neoplasms in the heart and liver when 18 days old. Third tissue-culture passage of fluid from the minced rabbit nodule showed cytopathic changes and fourth tissue-culture passage fluid was used for inoculating a litter of new-born rabbits. 1 ml. of tissue-culture fluid was injected into each rabbit One rabbit developed subcutaneous nodules and died at 13 days of age; another died on the fourteenth day and no nodules could be found. Multiple subcutaneous nodules developed in each of the six remaining rabbits at 25 days of age. The results of the inoculation of rabbits with tissue-culture-grown *SE* polyoma virus are summarized in Table 1. With the exception of the last litter of rabbits that were injected with virus 63 days before, the nodules disappeared when the rabbits were 93–134 days old.

It may be noted that no tumours developed when the animals were inoculated with one virus line

Table 1. INDUCTION OF SUBCUTANEOUS NODULES IN RABBITS INOCULATED SUBCUTANEOUSLY WHEN < 1 DAY OF AGE WITH *SE* POLYOMA VIRUS PROPAGATED IN MOUSE EMBRYO CELL CULTURES

Virus line	Litter No.	No. of rabbits			
		Injected	Dead and no nodules	With nodules	Living and no nodules
3919	1	5	2	2	1
581	2	7	1	0	6
695	3	7	1	6*	0
877	4	3	0	3	0
877	5	2	1	1	0
*R*1517	6	8	1	7	0
Total		32		19 (59%)	

* Tissue from a subcutaneous nodule from one rabbit was used to initiate virus line *R*1517.

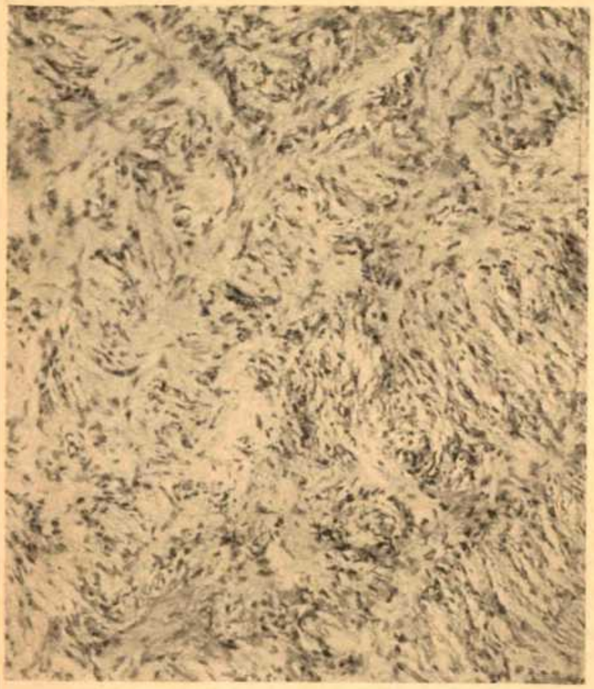

Fig. 2. A cellular area of a subcutaneous nodule. Interdigitating bundles of proliferating fibroblasts may be noted (hæmatoxylin and eosin). (× 135)

preparation. *In vitro* tests[7,8] had not been developed at the time these animals were injected, so it is unknown whether the tissue-culture fluid had a low virus content or whether the rabbits were resistant to the virus.

Nodules were excised from the living rabbits, fixed in Tellyesnicsky's formalin–acetic acid alcohol fluid[9], embedded, sectioned and stained with hæmatoxylin and eosin.

Histologically, the subcutaneous nodules were well circumscribed but not encapsulated (Fig. 2). There were interdigitating bundles of proliferating fibroblasts with plump nuclei seen against a background of pink collagenous tissue. The nodules were more cellular at the periphery and became relatively acellular toward the centre, when a tendency to form collagen was seen with an increase in hæmatoxylin-staining properties of the cells. In areas where cellular detail was sufficient the cells were fusiform with elongated nuclei and fibrillated cytoplasm. Some of the nodules were surrounded by a band of lymphocytes and neutrophils.

These nodules resembled certain fibrous growths in humans. They have been described and characterized by Stout[10] and are generally called fibromatoses. The fibrous growths are of limited growth potential and often regress as did the nodules in the rabbits.

The development of benign rather than malignant growths may be a reflexion of species differences in response of the host to the *SE* polyoma virus. The malignant growths in the different species of animals thus far studied vary. In the mouse, pleomorphic parotid gland tumours are most frequently seen but a variety of other neoplasms are also present. As many as eight histologically different tumours have been induced in one mouse. Multiple sarcomas and angiomatous lesions develop most often in the heart, liver and kidneys of the hamster, and sarcomas or angiomatous lesions occur in the kidneys or subcutaneous tissue of the rat.

(Since these experiments were completed, humoral antibodies for the *SE* polyoma virus have been demonstrated in rabbits after the nodules had regressed. Mice and hamsters bearing virus-induced tumours also develop humoral antibodies[11,12].)

Freeze-drying of *Harposporium anguillulae* Lohde in its Nematode Host

RECENT attempts to use predacious fungi for the biological control of nematodes have shown the desirability of maintaining adequate supplies of infective material for laboratory and field studies. Many of these fungi can be grown in pure culture on synthetic media, but some grow with difficulty and others only in their hosts.

The freeze-drying of masses of fungus mycelium and spores might be a useful method of maintaining stocks of these obligate parasites. This was attempted using the endozoic fungus *Harposporium anguillulae* Lohde, which was recovered from the sandy soil of a Florida citrus grove infested with the burrowing nematode *Radopholus similis* (Cobb) Thorne. At this time, Aschner's[1] work on the isolation of this fungus in pure culture was not known, and the fungus was carried in living nematodes of the genera *Rhabditis* and *Panagrellus* growing on corn-meal agar plates. Cultures were readily transferred to disease-free nematodes growing on other corn-meal agar plates or swimming in tubes of sterile distilled water. Thousands of infected nematodes were reared in this fashion. The signs of infection appeared after 3–5 weeks at 22° C. Both types of cultures were freeze-dried.

The apparatus consisted of a 'Cenco Hyvac' pump, a 2-l. Dewar flask charged with a mixture of ethylene glycol and dry ice, a 2-l., three-necked flask for freezing the water vapour, and two 500-ml. drying flasks. All fittings were 'Pyrex' brand standard taper glass. The drying was carried out at about − 28° C. and at a vacuum of less than 0·5 mm. of mercury. The agar and fungus-infected nematodes were removed from the Petri dishes, placed in a Waring blendor, some sterile distilled water added and the mass homogenized for 1 min. The viscous mass was diluted with sterile distilled water to make up 100 ml. and 50 ml. were frozen into a thin film on the inner wall of each of the drying flasks, which were immediately evacuated. Drying took 8–10 hr. The resultant fluffy powder was dispensed into a glass jar which was sealed and kept at 22° C. Microscopic examination of the powder revealed large numbers of dead but intact nematodes, and the presence of mycelium and spores of *Harposporium* as well as other fungi.

At weekly intervals 10 mgm. lots of the powder were placed on corn-meal agar plates containing disease-free nematodes. After 3–5 weeks nematodes infected with *Harposporium* were observed, indicating that the viability and virulence of the frozen, dried fungus was not materially reduced. The disease developed in the usual manner and no morphological changes appeared in the fungus after freeze-drying. To date, the dried *Harposporium* powder has retained its activity and virulence for periods ranging up to 4 months from the date of drying.

In view of these results, attempts will be made to freeze-dry other predacious fungi, including those which can be readily grown in pure culture.

GEOLOGY and PALÆONTOLOGY

How old is the Cambrian System ?

IN a recent contribution in *Nature*, Mayne, Lambert and York[1] have reported the results of age determinations on some British igneous rocks studied in the University of Oxford, and have concluded that the geological time-scale established in the works of Holmes (and of Marble and Belousov) is seriously in error. They claim that the age of 450 million years commonly assigned to Upper Cambrian strata is much too young, and that the base of the Cambrian System should be dated not at 500–520 m.y., but at about 750 m.y. This proposed drastic revision of the most significant date-line in geochronology conflicts somewhat with a large body of recent information to which, apparently, the authors have not had access.

The dating of the Cambrian system has hitherto been based largely upon determinations of the age of Swedish kolm, a mode of calibration which (as the Oxford authors correctly conclude) is very much open to criticism. Kolm is a uranium-rich hydrocarbon occurring within the trilobite sub-zones *Peltura minor* and *Peltura scarabaeoides* in the Upper Cambrian alum shales of Sweden, particularly in Närke and in the Billingen-Falbygden district of Västergötland. It forms lenses, sometimes coalescing into continuous seams, averaging 4 cm. but exceptionally reaching 20 cm. in thickness ; and some twenty unpublished analyses of representative samples made for me when I carried out an economic survey of the Västergötland field in 1945 show an ash content roughly from 19 to 45 per cent, with between 2·91 and 0·51 per cent U_3O_8 in the ash. The oil-shale country-rock carries 0·02–0·04 per cent U_3O_8. The apparent age of the kolm, from determinations by Nier and by Cobb and Kulp[2], is : lead-206/uranium-238, 355–455 m.y. ; lead-207/uranium-235, 420–480 m.y. ; lead-207/lead-206, 650–945 m.y. This discordant pattern of these ages has been attributed by all previous workers to loss of radon and perhaps some loss of lead, notwithstanding an inability to demonstrate a high loss of radon at ordinary temperatures and the manifest incompatibility between hypotheses demanding loss of radon through notional thermal alteration and the presence in the alum shales of a commercial content (4–7 per cent) of oil.

The usefulness of kolm as a geochronological date-line rests wholly upon the hitherto undebated assumption that it acquired its uranium content when the associated trilobites were alive. But there is no evidence to support this premise and much to refute it. Many recent studies have shown that sedimentary hydrocarbons continue to adsorb uranium and other metals from percolating ground-waters long after they were deposited : as an extreme example, a Palæozoic coal may become enriched in uranium from a Mesozoic or Cainozoic radioactive deposit nearby. While, therefore, it seems likely that the kolm originated as a penecontemporaneous segregation of sapropelic gel during the diagenesis of the bituminous sediments, the probability is that for long after lithification it continued to adsorb uranium and perhaps a little lead. For the source of these metals, epigenetic to the kolm, one has to look no further than the surrounding uraniferous oil-shales, in which the metals are syngenetic. As these shales contain old radiogenic lead, the isotopic composition of lead within the kolm will not necessarily be related in any equivalent manner to the uranium there, though because of the extreme simplicity of the regional tectonics there will be but little local variation in the lead – uranium ratios. This interpretation explains the many chemical differences between the kolm and the shale (for example, the much higher sulphur content in the latter, calculated ash-free) and for the first time rationalizes the anomalous age determinations. The most that can be deduced from these figures is that the Upper Cambrian is younger than 650 m.y., the age given by the lowest recorded lead-207/lead-206 ratio.

Fortunately, the claim that "it would be particularly desirable to have unambiguous dates from the Ordovician and Cambrian"[1] has already been answered by Russian investigators[3–5]. For the earlier system a lower limit is set by the age of granite pebbles occurring in a Cambrian basement conglomerate in the Patomskoe uplands of Northern Irkutsk, where there is but a slight hiatus between Upper Proterozoic and Lower Cambrian strata. A granite pebble from this conglomerate gives a potassium/argon age of 464 m.y. determined on the rock, and 566 m.y. determined on mica from the rock. (Another pebble gives a value of 626 m.y., with 763 m.y. on the mica.) An upper limit is set by the Mainsk and Tannuol'sk granites of Tuva, which are intruded into Middle–Upper Cambrian strata and which shed pebbles into overlying Lower Ordovician conglomerates. The Tannu Ola granite is dated by Ivanova and Polevaya, in two potassium/argon determinations on the rock, at 443–448 m.y. Confirmatory determinations are to be found in an argon dating of basalt lava interstratified with reputedly Lower Cambrian (unfossiliferous) sediments in the Volynian series of Belorussia, with an age of 480 m.y., and in a comparable value, 490 m.y., arrived at for an extrusive porphyry interbedded with Lower Cambrian trilobite-bearing strata in Tuva. Even if these latter figures were increased by 20 per cent to bring 'rock-ages' (possibly low through escape of argon from feldspars) into line with 'mica-ages', the Lower Cambrian would not be more than 600 m.y. old.

Additional evidence of quite a novel kind, based on the calcium-40/potassium-40 ratio in sylvite, has just become available from the Radium Institute of Leningrad[6] in a paper which reports the age of a fossiliferous Lower Cambrian potash salt deposit in the Irkutsk region of 620 ± 20 m.y.

A greater age for the Cambrian system is also ruled out by the history of mineralization in Katanga, Belgian Congo[7,8]. Here the uraninite of Shinkolobwe, Kalongwe and Luishya has an age of 600–620 m.y., this being one of the firmest dates in the geological record; and this uranium mineralization is now known to have accompanied the last stages of folding in the Kundelungun geosyncline, at a period which cannot have greatly post-dated the youngest Kundelungun sediments[9,10]. These strata have locally a lithological character potentially very favourable to the preservation of fossils; but a full examination in the course of mining operations has demonstrated that they are devoid of vestiges of life other than stromatolites, micro-algæ and sponge spicules. In other words, at round about 650 m.y. ago a Cambrian fauna had not yet developed.

Recently, Polevaya[3] has published argon datings on twenty-nine post-Proterozoic lavas collected from known geological horizons throughout the stratigraphical column. All but one of her values, without any correction for argon leakage, fit quite well into the Holmes-Marble scale. That loss of argon must have taken place is nevertheless evident from Gerling's extensive studies on the White Sea pegmatites[4], where the average argon leakage from feldspar is 23 per cent, argon datings on micas agreeing excellently with well-established uranium ages. Presumably, therefore, an empirical correction not exceeding 20 per cent must be made in the argon dating of rocks such as liparites, felsites and porphyries when the determination is made on the whole rock and not on separated mica. Such a correction will result in an extension of the Holmes scale going nearly half-way towards the proposals of the Oxford group. On this revised chronology, the base of the Cambrian is dated at about 600 m.y.

PROF. C. F. DAVIDSON has presented no new evidence free from unambiguous interpretation which would refute our proposed extension of the Holmes *B* time-scale; or indeed on which an alternative scale could be based. The examples which he cites form only a part of a large number of such data which we have considered. We have rejected them because either the stratigraphy of the samples or their measured age is not free from unwarranted assumptions. We have used only samples which are above criticism on these points. We would, however, like to correct Prof. Davidson's remark that we "claim that the base of the Cambrian System should be . . . at about 750 m.y.". In fact, we have avoided using the rather meaningless term 'base of the Cambrian', and we have but estimated, by extrapolation from our oldest measured date at around 500 m.y., that the upper Cambrian "should be closer to 650 m.y.". Prof. Davidson's recapitulation of a possible geochemical history of the kolm emphasizes our conclusion that this material provides a poor calibration point. The pattern of discordancy[1] found for lead ages of the kolm material would not justify his argument that the kolm is younger than 650 m.y. Nevertheless, such an age is not incompatible with an extrapolation of our scale. Considering that the precision of measurement is not better than 5 per cent, this extrapolation could give an age for the top of the Cambrian between 600 and 650 m.y., and clearly this age also depends greatly on the (unknown) length of the Ordovician.

It has been known for a long time that loss of radiogenic argon can occur to a variable extent in some minerals which show no apparent alteration, notably potassium felspar. Thus Prof. Davidson's interpretation of the Russian argon/potassium age values is not justified. This variable loss is often found to be greater than the 23 per cent measured by Gerling for pegmatitic felspar from a particular locality. Its extent is unpredictable *a priori* in any particular sample, although many measurements in the range 300–600 m.y. show a loss greater than 30 per cent. (It is because of this uncertainty that we attach little importance to our interpretation of the age of the Mynydd Mawr microgranite, and the Dubuque felspar.) It is therefore meaningless to use an average percentage loss in order to assess the true age with sufficient precision from whole rock analysis. The whole-rock age-value of lavas and similar very fine-grained rocks may be even more seriously affected on account of the extremely fine grain of the potassium minerals in it. Whole-rock analysis is not yet sufficiently precise for defining a time-scale; and there is certainly no foundation for presuming that "an empirical correction not exceeding 20 per cent must be made in the argon dating of rocks such as liparites, felsites and porphyries, when the determination is made on the whole rock and not on separated mica". In fact, the empirical correction would be particular to each sample, and largely unknown—especially for lavas. Thus the only Russian measurements which are relevant are those on the mica separated from granite pebbles found in Lower Cambrian rocks. Two values are given, 566 m.y. and 763 m.y., and there seems to be no reason to prefer the younger of these as Davidson has done, or indeed, with such disagreement, either of them.

The calcium–potassium method of dating was first used by Inghram *et al.*[2]. The results of its application have shown poor agreement with best-age values, and the analytical errors may be high[3]. Sylvite is an unsuitable mineral to use for dating geological events, since it is subject to recrystallization. We have no knowledge of the geological or analytical details of the Leningrad sample, so it is difficult for us to decide if it fulfils the stringent requirements of a calibration sample. The problem of dating the Ordovician and Cambrian remains.

A close examination of the geology of the Shinkolobwe uranium deposit shows that it is far from being "one of the most certain points in the geologic time scale" (Prof. J. L. Kulp, in Robert, ref. 4, p. 17). Thus, although the age of 630 ± 35 m.y. (as quoted by Robert) is generally agreed to be unusually good, the Shinkolobwe deposit is of no use in defining a time-scale. The precise facts are that the uranium minerals are present in veins of mesothermal type occurring within folded dolomites of the Système Schisto-dolomitique of Katanga. These dolomites and other similarly folded dolomites overlying them in nearby areas contain *Collenia* and *Stromatolithes*, fossils known to exist from the early pre-Cambrian to the Cambro-Ordovician inclusive. The stratigraphic definition of the uranium deposits is therefore of the poorest. The absence of ordinary marine lower-palæozoic faunas is of no weight in this argument, as they are generally unknown from South and Central Africa. We have discussed these remarks on the African samples with Prof. J. L. Kulp, and we learn that his original statement did not refer to the stratigraphy, but to the measured age.

Synthetic Carbonatite Magma

JUDGING from the literature during the past decade, there is a growing interest in problems related to the genesis of carbonatites and associated alkaline igneous rocks. The interest has undoubtedly been fostered by the discovery of large reserves of rare earths in these rocks. Many field geologists believe that carbonatites were emplaced as liquid magmas ; but hitherto there has been no conclusive experimental evidence to support the existence of carbonatite liquids. In fact, from the available experimental evidence it seemed unlikely that such liquids could exist at the low temperatures indicated by field studies. We have recently obtained experimental evidence that simplified carbonatite magmas can exist at moderate temperatures through a wide range of pressures.

Results[1] from a study of the join calcite–water in the ternary system $CaO–CO_2–H_2O$ show that calcite begins to melt at a temperature of 740° C. at 1,000 bars pressure of water vapour. Only a trace of liquid was developed at this temperature, but the amount increased with increasing water content and with increasing temperature. This evidence implied, but did not prove, the existence of carbonatite magmas.

Subsequent studies on the system $CaO–CO_2–H_2O$ have shown that the minimum liquidus temperature at 1,000 bars pressure is 675° C. ± 5° C. At this temperature and pressure, a liquid with the composition calcium oxide 64, carbon dioxide 18, water 18 (weight per cent) is in equilibrium with calcite, portlandite and vapour (almost pure water). At 680° C. and the same pressure, a liquid develops on the calcium oxide side of the $Ca(OH)_2–CaCO_3$ join ; this is in equilibrium with calcite, portlandite and calcium oxide and has a composition calcium oxide 68, carbon dioxide 19, water 13 (weight per cent). At 685° C. the two liquid fields coalesce and at still higher temperatures the range of composition of the liquid field increases. The minimum liquidus temperature in the system has been determined for a range of pressures. At 500 bars the temperature is 680° C., and at 4,000 bars it is lowered to 640° C. At pressures lower than 50 bars, the minimum liquidus temperature decreases, and at 27 bars pressure the appropriate composition is completely liquid at 665° C. The high melting temperature of calcite is therefore lowered markedly by the addition of calcium oxide and water under pressure. The low-temperature liquid may be regarded as a simplified carbonatite magma. Although calcite is generally the dominant mineral in carbonatites, dolomite is frequently an important constituent, while apatite and mica are constant accessories. Experiments are under way to find the effect of additional components (such as magnesium oxide, phosphorus pentoxide, silicon dioxide and alkalis) on the minimum liquidus temperature in the ternary system. Solubility determinations are also being made to see how the solubility of calcite varies with increasing content of carbon dioxide in the aqueous vapour phase. Many geologists believe that a high-temperature vapour, consisting of water and carbon dioxide, is able to dissolve large amounts of calcium oxide, magnesium oxide, ferrous oxide, etc.

Detailed results of these studies will be published in due course, but we take this opportunity of presenting these facts now because they will be of interest to geologists working on carbonatites.

Manganese in Modern and Fossil Gastropod Shells

VERY little work has been done on manganese concentrations in shell material and particularly in gastropod shells, although Doring in Vinogradov's book[1] reported several analyses and found from 0·1 to 0·0001 per cent manganese by weight in gastropod shells. Krinsley and Bieri[2] have determined manganese in the shells of modern and fossil pteropods.

This trace element was examined in modern and fossil shells to determine whether burial and subsequent diagenesis might have altered the original material.

Eighty modern and fossil shells of *Olivella biplicata* (Sowerby), 89 of *Tegula funebralis* (A. Adams) and

Z Middle Pleistocene San Pedro, California 33° 45′ N., 118° 17′ W.	11	100	10	17	81	10			

Localities *Y* and *Z* represent equivalent ages.

49 of *Fissurella volcano* Reeve were analysed for manganese with a 21-ft. grating spectrograph[3]. Aragonite percentages were determined with a North American Phillips X-ray diffraction unit, using the method reported by Chave[4] with modification. (Note that each locality listed in Table 1 represents the mean of approximately ten specimens analysed in duplicate.) The specimens were carefully hand-cleaned to eliminate any material on external and internal shell surfaces. The error involved in the spectrographic analyses was ± 20 per cent of the amount present.

Since manganese, because of its size, will theoretically fit more readily into the calcite than the aragonite structure, one would expect to find more manganese in calcitic shells than aragonitic ones. However, the amount of manganese in the shell material analysed is small, and the results are inconclusive (Table 1) with respect to modern specimens.

Post-depositional changes have increased the amount of manganese in some of the fossil shells (Table 1). *Tegula* and *Olivella* fossil shells have more manganese than modern shells with the exception of *Olivella* at locality *Y*, which has the same amount as modern specimens. *Fissurella* modern and fossil shells contain the same concentrations of manganese. One might at first suspect that the larger manganese concentrations in some of the fossils were due to surface contamination from the sediment matrix, even though the specimens were carefully cleaned. However, this is shown to be unlikely by the 19 analyses of fossil *Fissurella* at locality *X* and *Olivella* at locality *Y*, which do not differ from the modern shells.

No recrystallization of shell material has occurred in *Olivella* as indicated by lack of change in calcite–aragonite ratios in the fossils. Probably little or no recrystallization has occurred in *Tegula*; the aragonite percentages in fossil *Tegula* are higher than those in modern forms. Recrystallization always lowers the aragonite content.

Two groups of *Tegula* specimens were selected at Palos Verdes, California (Table 1). Group *D* was collected alive on rocks at the edge of the beach and killed, while group *C* was collected from shell heaps on the beach. All other *Tegula* specimens were collected alive. The age of group *C* is impossible to determine; but the shells have undoubtedly been subjected to alternate wetting and drying after death or may even have been under water for some time. In any event, no increase in manganese has occurred in group *C*, indicating that the processes which have added manganese to the shells probably occur largely after burial.

If the mean manganese content at a given fossil locality in a particular species is higher than in modern specimens, then the manganese variation in that population is found to be correspondingly high. Manganese would be expected to accumulate at different rates in individual fossils and thereby increase variation in the fossil populations. This increased variation, which is not characteristic of any of the modern specimens, is another indication that addition of manganese has occurred after burial. If no alteration of the shell material at a particular fossil locality has occurred, fossil variation will approximate modern variation.

The increase in manganese in some of the fossils is due partially to diffusion from the surrounding sediments into the shell material (assuming that the fossils originally had approximately the same composition as the modern animals). The size of the shell crystals, the differing construction of shell material in the various species examined[5], chance contact with other shells of higher manganese content and, more important, diagenetic conditions at a particular locality, probably determine whether increase of manganese in fossil shells has occurred. It is impossible at present to separate these factors; but diffusion experiments and a more thorough knowledge of the construction of shell material should help solve the problem.

STATISTICS

Matching and Prediction in the Social Sciences

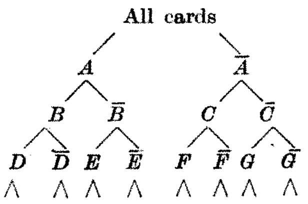
Matching processes are constantly in use in the social sciences. Often their use is explicit, as in studies of the relative effects of different experiences or procedures. In other cases they are implicit, as in the use of specific controls for the selection of consumer panels or in quota surveys. They are also implicit in many extrapolation processes. Even so, the variables used for matching processes are in most cases of non-empirical origin, and are selected on the basis of either custom or hunch. The result may well be that the matching is inadequate, sometimes completely so.

Empirical procedures can, of course, be used. The principle of the empirical method is that, for a variable to be relevant in matching, it must be correlated to some appreciable degree with whatever it is that is being studied (for example, a specific attitude, buying behaviour). If all the proposed matching variables are arranged in a correlation matrix, multiple correlation methods[1] can be used to select from them that combination of variables which gives the highest multiple correlation with whatever is being studied (that is, the criterion). These variables are then used as the basis for matching, and this usually proceeds through a form of prediction, perhaps involving the use of a regression equation.

This sort of work is, however, most arduous. Matching on the empirical principle requires that each fresh criterion must have its own set of matching variables. Also, the development of a correlation matrix is specially inadequate where many of the available variables involve a 'yes' or 'no' response.

Several years ago I developed a technique of the latter kind and have used it in various inquiries[2,3]. But a much simpler and more adequate technique can be used, and I have applied this in more recent studies[4].

The method involves matching on the principle of simple classification. Suppose the matching is being done to allow the study of the effect of different stimuli on criterion X. The following steps are involved. (*a*) Numerous proposed matching variables are included in the testing phase. (*b*) Each of them is then analysed against score on criterion X, and that one which has the greatest association with, or power to predict, the criterion score is selected as the first-stage predictor (or matching variable). This variable will then serve to split the record cards of the informants into at least two groups, A and $\bar{A}$. (*c*) Next, this process is repeated with all the cards in pack A, and the variable with the highest predictive power is selected as the second-stage predictor within that pack. Call this one B, and let it split the A pack into groups B and $\bar{B}$. (*d*) Now repeat the process with pack $\bar{A}$ and select the best predictor within that pack. Call this C and let it split $\bar{A}$ into C and $\bar{C}$.



The vital point here is that the second-stage predictor in pack A is not necessarily the same as the second-stage predictor in pack $\bar{A}$. In other words, what matters in one group may well differ from what matters in another. Multiple correlation procedures do not allow for this. (*e*) The splitting process is continued, so far as it can be taken, on the pattern shown above. The final set of categories or sub-groups defines the matching composite.

There is no need to employ only two-way splits of card packs. Three or more splits can be used at any stage.

The device for selecting any one predictor in the composite is a simplified version of the chi square calculation. The cards are analysed on a four-cell system: 'high' versus 'low' scores on the criterion test and 'yes' versus 'no' on the item being tested as a possible matching variable. The matching power of this trial item is given in the form of a direct count of the number of cases in the four cells which deviate from what might be expected on a null hypothesis (that is, a hypothesis of no association or predictive power at all). Matching power so derived is more accurate than when gauged from most correlation coefficients. It is on the basis of this selection procedure that the final matching composite is built up as described above.

The use of the selected composite of matching variables to achieve matching is also very straightforward. Suppose that in the study of criterion X (for example, buying behaviour), the record cards for sample I are to be matched to those for sample II. (*a*) Split each sample into sub-groups on the above pattern. Suppose this yields 40 sub-groups (for each sample). (*b*) Now equate the number of cards in each sub-group (in the sample I pack) to its equivalent sub-group in the sample II pack. This can be done on random principles, but the equating process must not involve throwing out more than a few record cards. Discarding of cards can be all but avoided if the device is used of multiplying all the pack II sub-groups by a constant sufficient to raise their numbers well above the general level of the numbers in pack I. This constant may be 2 or 3 or 4 depending on the relative sizes of the two samples. (*c*) Alternatively, the average criterion score for each sub-group in pack I can be weighted (separately) by the number of cards in the equivalent sub-group in pack II. In this way, there need be no loss of cards at all, though slight statistical problems may arise.

I have been using the 'classification system' of matching since 1957. There are points at which it is similar to the technique described in the recent communication by Williams and Lance[5].

FORTHCOMING EVENTS

*(Meetings marked with an asterisk * are open to the public)*

Monday, March 16

Royal Institution, Library Circle (at 21 Albemarle Street. London, W.1), at 5.30 p.m.—Four short talks on "Books from the R.I. Library".

Society of Chemical Industry, Pesticides Group (at 14 Belgrave Square, London, S.W.1), at 5.30 p.m.—Mr. J. E. H. Grose: "Problems in Stomoxys Research in East Africa".

Institution of Electrical Engineers, London Graduate and Student Section (at Savoy Place, London, W.C.2), at 6 p.m.—Mr. G. O. McLean: "Something for Nothing? Heat Pump Achievements".

Northampton College of Advanced Technology (at St. John Street, London, E.C.1), at 6 p.m.—Dr. Dimitri Riabouchinsky (L'Académie des Sciences de l'Institut de France): "The Hydraulic Analogy and Air Resistance".

Institute of Metal Finishing (at the Northampton College of Advanced Technology, St. John Street, London, E.C.1), at 6.15 p.m. —Prof. Ernst Raub: "Hydrogen Content of Electro-Deposits".

Tuesday, March 17

Institution of Chemical Engineers (at Church House, Westminster, London, S.W.1), at 9.30 a.m.—Spring Meeting.

Institution of Electrical Engineers, Measurement and Control Section (at Savoy Place, London, W.C.2), at 5.30 p.m.—Mr. G. Phillips: Informal lecture on "Electrical Uses of Atomic Spin".

Plastics Institute, London and District Section (at the Wellcome Building, 183–193 Euston Road, London, N.W.1), at 6.30 p.m.—Mr. D. S. Mahon: "Plastics—Why should I Worry?" (Chairman's Lecture).

Tuesday, March 17—Thursday, March 19

Oil and Colour Chemists' Association (at the Royal Horticultural Society's New Hall, Greycoat and Elverton Streets, London, S.W.1)—Eleventh Technical Exhibition.*

Tuesday, March 17—Saturday, March 21

Eighth Electrical Engineers (A.S.E.E.) Exhibition (at Earls Court, London).

Wednesday, March 18

Royal Society of Arts (at John Adam Street, Adelphi, London, W.C.2), at 2.30 p.m.—Dr. B. A. Southgate: "A Study of the Pollution of the Thames Estuary".

Physical Society, Colour Group (at the Institute of Ophthalmology, Judd Street, London, W.C.1), at 3 p.m.—Mr. A. W. S. Tarrant: "How Reproducible are Standard Illuminants?". 4.45 p.m.—Discussion on "Illuminants B and C" introduced by Mr. J. Guild and Mr. F. Warburton.

Geological Society of London (at Burlington House, Piccadilly, London, W.1), at 5 p.m.—Prof. B. C. King: "Problems of Pre-Cambrian Correlation in Western and Central Uganda".

Royal Meteorological Society (at 49 Cromwell Road, London, S.W.7), at 5 p.m.—Mr. H. H. Lamb: "The Southern Westerlies—a Preliminary Survey; Main Characteristics and Apparent Associations"; Mr. W. T. Roach and Mr. R. M. Goody: "Absorption and Emission in the Atmospheric Window from 770 to 1,250 $cm.^{-1}$".

Royal Statistical Society (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 5.15 p.m.—Mr. W. E. Thomson: "ERNIE—a Mathematical and Statistical Analysis".

Eugenics Society (at the Royal Society, Burlington House, Piccadilly, London, W.1), at 5.30 p.m.—Mr. R. W. Parnell: "Physique and Family Structure".*

Institution of Electrical Engineers, Radio and Telecommunication Section (at Savoy Place, London, W.C.2), at 5.30 p.m.—Mr. C. W. Oatley: "New Amplifying Techniques".

Royal Institute of Chemistry; The Classical Association; and the Haldane Society (at the William Beveridge Hall, Senate House, University of London, W.C.1), at 5.30 p.m.—Debate on the motion "That the Education of our Future Rulers should be Primarily in the Sciences rather than in the Humanities". Chairman: Prof. Sir Cyril Hinshelwood, F.R.S. Proposer, Sir Alexander Fleck, K.B.E., F.R.S. Opposer: Prof. B. Farrington. Seconder for the Motion: Prof. A. R. Ubbelhode, F.R.S. Seconder against the Motion: Prof. W. Beare.

University College, Department of Pharmacology (in the Physiology Theatre, Gower Street, London, W.C.1), at 5.30 p.m.—Dr. Valy Menkin (Temple University, Philadelphia): "Biochemical Mechanisms Involved in Inflammation".*

British Computer Society (at the Northampton College of Advanced Technology, St. John Street, London, E.C.1), at 6.15 p.m. —Mr. C. E. G. Bailey: "An Approach to Learning and Teaching Machines".

Society of Chemical Industry, Corrosion Group (at 14 Belgrave Square, London, S.W.1), at 6.30 p.m.—Mr. A. Keynes: "Economic Aspects of Corrosion".

Thursday, March 19

Physical Society, Optical Group (in the Physics Department, Imperial College, London, S.W.7), at 2.30 p.m.—18th Annual General Meeting.

Royal Society (at Burlington House, Piccadilly, London, W.1), at 4.15 p.m.—Meeting for Election of Fellows. 4.30 p.m.—Mr. D. Brennan and Mr. P. C. Fletcher: "The Atomization of Hydrogen on Tungsten"; Mr. G. A. Gilbert: "Sedimentation and Electrophoresis of Interacting Substances. 1: Idealized Boundary Shape for a Single Substance Aggregating Reversibly".

Institution of Mining and Metallurgy (at the Geological Society of London, Burlington House, Piccadilly, London, W.1), at 5 p.m.—Mr. F. A. Williams: "Recovery of Semiheavy Minerals in Jigs"; Mr. D. C. Shelton: "Santa Barbara Mill, Chihuahua, Mexico".

Linnean Society of London (at Burlington House, Piccadilly, London, W.1), at 5 p.m.—Dr. Kathleen I. M. Chesters: "Ecological Conditions in the Early Tertiary of Great Britain"; Prof. Tom Harris F.R.S.: "The Possibilities of Palæo-ecology in the Jurassic"; Dr. William S. Lacey: "Some Aspects of Palæo-ecology in the Karroo of Rhodesia and Nyasaland".

London Mathematical Society (at the Royal Astronomical Society, Burlington House, Piccadilly, London, W.1), at 5 p.m.—Prof. B. Huppert: "Composition-series of Finite Groups".

Royal Aeronautical Society (at the Institution of Civil Engineers, Great George Street, London, S.W.1), at 6 p.m.—Mr. E. C. Cornford: "Long Range Missiles".

Society of Chemical Industry, Road and Building Materials Group (at 14 Belgrave Square, London, S.W.1), at 6 p.m.—Mr. D. A. Dowdeswell: "Slag for Roadmaking".

British Institution of Radio Engineers, Medical Electronics Group (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 6.30 p.m.—Dr. H. Wolff: "Instrumentation in Field Physiology".

Royal Society of Tropical Medicine and Hygiene (at the Royal Army Medical College, Millbank, London, S.W.1), at 7.30 p.m. —Laboratory Meeting. Chairman: Sir John Boyd, O.B.E., F.R.S.

British Institute of Radiology, incorporated with the Rontgen Society (at 32 Welbeck Street, London, W.1), at 8 p.m.—Mr. D. A. Wilson: "Some Health and Safety Problems".

Thursday, March 19—Friday, March 20

Physical Society (at Birkbeck College, Malet Street, London, W.C.1), at 9.30 a.m. daily—Symposium on "Fluctuation Phenomena and Stochastic Processes".

Society of Chemical Industry, London Section (in the Beveridge Hall, Senate House, University of London, W.C.1), at 2.15 p.m. on Thursday and 9.30 a.m. on Friday—Symposium on "Costing in the Chemical Indnstry".

Institution of Electrical Engineers, Radio and Telecommunication Section (at Savoy Place, London, W.C.2)—Convention on "Stereophonic Sound Recording, Reproduction and Broadcasting".

National Association for Mental Health (at the Assembly Hall, Church House, Westminster, London, S.W.1), at 10 a.m. daily—Conference on "The Place of Work in the Treatment of Mental Disorder".

Friday, March 20

Society for Water Treatment and Examination (in the Library, Royal Society of Health, 90 Buckingham Palace Road, London, S.W.1), at 9.30 a.m.—Seventh Annual General Meeting.

Biochemical Society (in the Department of Biochemistry, The University, South Parks Road, Oxford), at 11 a.m.—381st Meeting.

Royal Astronomical Society (at Burlington House, Piccadilly, London, W.1), at 4.15 p.m.—Discussion of geophysical papers received during the Session. Chairman: Dr. R. Stoneley, F.R.S. Speakers will include Dr. A. H. Cook, Mr. C. Jones and Dr. R. L. G. Gilbert.*

Institute of Navigation (at the Royal Geographical Society, 1 Kensington Gore, London, S.W.7), at 5.15 p.m.—Captain F. J. Wylie, R.N.: "The Impact of Radar on the Rules of the Road at Sea".

Institution of Electrical Engineers (joint meeting with the Institutions of Civil and of Mechanical Engineers, at the Institution of Mechanical Engineers, 1 Birdcage Walk, London, S.W.1), at 6 p.m.—Sir Harold Plant: Fifth Graham Clark Lecture.

Institution of Electronics (in the Assembly Hall of the University of London Institute of Education, Malet Street, London, W.C.1), at 7 p.m.—Mr. L. E. A. Bourn: "The Electronic Organ".

Royal Institution (at 21 Albemarle Street, London, W.1), at 9 p.m.—Air Commodore W. K. Stewart: "Man as a Controller of Flight Vehicles".

Saturday, March 21

Linnean Society of London, Palæobotany Group (at Burlington House, Piccadilly, London, W.1), at 11 a.m.—Discussion on certain of the Proposals concerning the International Code of Botanical Nomenclature.

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Lecturer in Biochemistry—The Registrar, The Manchester College of Science and Technology, Manchester 1 (March 28).

Chair of Forensic Medicine; and Chair of Bacteriology in the University of Ceylon—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Ceylon, March 31).

Assistant Lecturers (2) in Pure Mathematics; Assistant Lecturers or Lecturers (3) in Applied Mathematics; a Lecturer in Statistics; an Assistant Lecturer (with special interests in experimental morphology or physiological ecology) in Botany; Junior Research Fellows (2) (with special interests in organic or inorganic chemistry) in Chemistry; a Lecturer (medically qualified) in Medical Genetics; and a Lecturer in Biochemistry—The Registrar, The University, Sheffield (April 4).

Assistant Lecturers or Lecturers in Pure Mathematics (two appointments); Physics, Civil Engineering, Mechanical Engineering, and Chemical Engineering: and an Assistant Lecturer in Geology—The Registrar, University College, Singleton Park, Swansea (April 4).

Research Assistant in the Department of Botany, to assist with research on aspects of nitrogen metabolism being conducted by Dr. G. E. Fogg and Dr. L. Fowden—The Secretary, University College, Gower Street, London, W.C.1 (April 4).

Senior Lecturer in Physics—The Registrar, The University, Sheffield (April 4).

Imperial Chemical Industries Fellows (preferably under 29 years of age) at Durham or Newcastle, for research in Engineering, Chemistry, Physics and allied subjects, including the biological application of chemistry—The Registrar, University Office, 46 North Bailey, Durham (April 6).

Research Fellow (with a Ph.D. degree or equivalent research experience) in the Chemistry Department, for work on fundamental aspects of heterogeneous catalysis, in collaboration with Dr. G. C. Bond—The Professor of Chemistry, The University, Hull (April 6).

Research Fellow (with a Ph.D. degree or equivalent research experience) in the Chemistry Department, for work on the kinetics of gaseous oxidation reactions, in collaboration with Dr. R. R. Baldwin—The Professor of Chemistry, The University, Hull (April 6).

Chair of Philosophy—The Registrar, University Office, 46 North Bailey, Durham (April 9).

Research Fellow (with an interest in physical-organic chemistry, and some postgraduate experience in preparative chemistry) in the Department of Chemistry—The Registrar, Queen Mary College (University of London), Mile End Road, London, E.1 (April 10).

Lecturer in Mathematics—The Secretary, The University, Aberdeen (April 11).

Lecturer (with good academic qualifications) in Botany—The Clerk to the Governors, Chelsea College of Science and Technology, Manresa Road, London, S.W.3 (April 13).

Lecturer in Physiology—The Secretary, The Queen's University, Belfast (April 15).

Lecturer in the Department of Metallurgy, to teach and carry out research in Physical Metallurgy—The Registrar, The University, Liverpool (April 18).

Lecturer or Assistant Lecturer in Experimental or Theoretical Physics at the University College of the West Indies—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (April 18).

Assistant Lecturer (honours graduate) in Chemistry—The Secretary, Bedford College (University of London), Regent's Park, London, N.W.1 (April 20).

Reader or Senior Lecturer in Soil Science; a Senior Lecturer or Lecturer in Horticulture; and a Senior Lecturer or Lecturer in Farm Mechanization and Irrigation at the University of Khartoum—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (April 20).

Assistant Director (with a good degree or equivalent qualification in a biological science, experience of annual and perennial crops, and preferably a knowledge of foreign languages and experience in editing scientific publications) of the Bureau of Horticulture and Plantation Crops, East Malling Research Station, East Malling, Maidstone, Kent—The Secretary, Commonwealth Agricultural Bureaux, Farnham House, Farnham Royal, Bucks (June 14).

Assistant Master to teach Mathematics up to University Scholarship level—The Headmaster, Tonbridge School, Tonbridge, Kent.

Head of the Chemistry Department—The Headmaster, Gordonstoun School, Elgin.

Master (not over 30, with at least a second-class honours degree) to teach Physics up to Lower Sixth form standard—The Headmaster, King's College School, Wimbledon, S.W.19.

Scientific Officer or Senior Scientific Officer (with a good honours degree or equivalent with training preferably in both physiology and physics), for research in the energy metabolism of farm animals using direct calorimetry—The Secretary, Rowett Research Institute, Bucksburn, Aberdeenshire.

Seed Mycologist (with a degree in botany, and preferably some postgraduate training) on the staff of the Official Seed Testing Station for England and Wales—The Secretary, National Institute of Agricultural Botany, Huntingdon Road, Cambridge.

Senior Scientific/Scientific Officer (with a first- or second-class honours degree in physics or physical chemistry or equivalent qualifications), to carry out research concerned with the development and application of solid-state electronic optical devices—The Senior Recruitment Officer, Atomic Weapons Research Establishment, Aldermaston, Berkshire, quoting Ref. 2174/34.

Soil Chemist (with an honours degree in chemistry, or in natural science including chemistry, and at least two years postgraduate training or experience as a Soil Chemist) at the West African Institute for Oil Palm Research, Nigeria, for the study and analysis of soil types with a view to improving soil conditions—The Director of Recruitment, Colonial Office, London, S.W.1, quoting BCD.197/199/016.

Statistician (with a good honours degree and preferably experience or an interest in agricultural experimentation) in the Department of Biometrics—The Secretary, The Grassland Research Institute, Hurley, near Maidenhead, Berks.

Technician or Junior Technician (G.C.E. (A)' standard), for biochemical and histological research—The Professor of Pathology, Royal College of Surgeons of England, Lincoln's Inn Fields, London, W.C.2, marking envelope "Path. Technician".

SP. 500 SPECTROPHOTOMETER

186 mμ

The Unicam SP.500 Ultraviolet and Visible Spectrophotometer is now fitted with a high grade silica prism which extends the useful working range of the instrument beyond 200 mμ to the region of atmospheric absorption at 186 mμ.

Better prism transmission gives the important advantage of reduced slit widths with a consequent reduction in stray light and increase in resolution, a facility which is especially valuable in the 190-240 mμ region.

A redesigned slit mechanism, in which static friction is virtually eliminated, allows the lowest slit widths to be accurately set and reproduced. Combined with the better transmission of the new prism, this feature greatly increases the scope of the instrument for high resolution determinations at the lower end of the spectral range.

PHYSICS AND HEAT TECHNOLOGY OF REACTORS

Supplement No. 1
of the Soviet Journal of Atomic Energy

Published in co-operation with
CONSULTANTS BUREAU, INC., NEW YORK

11 *in. by* 8½ *in.* 180 *pages* *Illustrated* 168*s. net*

The nineteen original papers in this important volume may be conveniently divided into two groups. The first deals with reactor physics: calculations; specialized experiments; reactor safety; and a variety of related problems. The second group is concerned more with engineering aspects: heat problems that arise in power reactors, and especially heat removal problems. Consideration is also given to the intimately related problem of radioactive loading of the reactor heat removal systems.

SCIENTIFIC CO-OPERATION IN THE COMMONWEALTH

THE U.S. National Academy of Science has undertaken, at the request of International Co-operation Administration, a study of the way in which the latter can most effectively use science and technology in technical assistance programmes in Africa south of the Sahara and north of the Union of South Africa. The broadening basis of co-operation is a theme of the latest annual report of the Rockefeller Foundation, and the increasing interest of the United States in scientific and technical work in Africa and in other relatively under-developed parts of the world has already been welcomed by Lord Hailsham. Quite apart from the Anglo-American agreement in the autumn of 1957 on scientific and technical co-operation, especially in defence, the general shortage of trained man-power has given scientific and technical co-operation to-day an importance even greater than it possessed before the Second World War. This is only partly due to the development of the technical assistance programmes both under the Colombo Plan and under the United Nations. It arises from the growing scale, complexity and costliness of scientific and technological research and from the growth, during and after that War, of obstacles to the interchange of knowledge and to the free discussion of scientific and technical work, as a result of political differences or real or imaginary considerations of national security.

Free movement of scientists and technologists from one country to another, both within and outside the British Commonwealth of Nations, has never been more desirable, both from the point of view of scientific and technical advance and from its contribution to international understanding and goodwill. Again, the free exchange of knowledge is increasingly essential from the economic point of view, while the recent international conference on scientific information at Washington indicated the impracticability of dealing with the immense volume of advancing knowledge except on a basis of international co-operation. Only international co-operation can enable mankind to reap the full benefits which nuclear power, radar, jet propulsion, radio astronomy and other advances have placed within our reach.

The address on scientific co-operation within the British Commonwealth which H.R.H. the Duke of Edinburgh delivered in Karachi on February 7 at the annual meeting of the Pakistan Association for the Advancement of Science (see *Nature* of February 14, p. 425) is thus particularly appropriate, for it is from such co-operation that any wider scientific co-operation of the United Kingdom should start. Following a lucid summary of the development of scientific co-operation within the Commonwealth, the Duke affirmed his conviction that the whole Commonwealth would benefit greatly from a larger movement of scientists, whether as students, research workers, teachers, or members of scientific expeditions, and he was concerned about how this could be encouraged in practice. Rightly he emphasized at the outset that informal co-operation arising out of personal and informal contacts between individual scientists is of supreme importance and even in volume probably exceeds organized co-operation.

That point needs to be kept in mind before proposing a new or elaborate organization for co-operation. The first essential is to secure the conditions which permit and encourage mobility and interchange in general, to remove the obstacles to personal contact, to free discussion and to the communication of ideas and knowledge. If the political and financial conditions are appropriate, even informal effort will go far to secure what is essential, and one important outcome of the new programme of Commonwealth scholarships and fellowships adopted in principle at the Montreal Commonwealth Trade and Economic Conference last September should be to foster such mobility; though it will be recalled that the conference which this year is to formulate the programme is also to review existing arrangements for co-operation between Commonwealth countries in the field of education generally.

The Duke of Edinburgh pointed out that the present pattern of scientific co-operation within the Commonwealth has five aspects: the regular discussion of general scientific problems and of problems particular to the Commonwealth; the discussion of problems of the administration of science and research; the regular exchange of scientific information; the movement of scientists; and technical help and advice. The last is particularly fostered under the Colombo Plan, the Scientific Council for Africa South of the Sahara, the Technical Assistance Administration of the United Nations, the expanded programme of technical assistance, as well as the 'Point Four' programme of the United States. The Colonial research reports give some idea of the amount of scientific co-operation that already takes place within the British Commonwealth. The latest report on the Colombo Plan for co-operative economic development in south and south-east Asia gives an impressive picture of the Commonwealth effort in technical assistance in that area alone. Besides the £3·71 million and 317 experts provided by the United Kingdom under the Technical Co-operation Scheme from its inception up to June 30, 1958, Australia has provided £2·8 million and 284 experts as well as 2,286 training awards; Canada, 5·2 million dollars, 126 experts and has trained 1,005 Fellows and scholars; while New Zealand has provided £897,000, 89 experts and training for 549 persons. India has provided training for 886 persons, while by the end of June 1958 member countries had contributed 6,952 scholarships and training awards. About half the total technical assistance expenditure under the Colombo Plan has been devoted to study and training courses, and there is now a marked tendency towards more rapid development of technical training facilities in the Colombo Plan area.

The cumulative effect of these developments must be considerable, and there is to be added to it that of the United States' own programmes of expanded aid, of the United Nations technical assistance programmes and that specifically provided to the dependent territories under Colonial Development and Welfare Schemes. The Commonwealth scholarship scheme proposed at Montreal last September will in due course add to the flow, and there are also the activities of commercial firms as well as of the Rockefeller Foundation, the Nuffield Trust, the Fulbright Programme, the British Council and the Marshall Aid Commemoration Scholarships. All these also encourage mobility, and the movement of students, scientists and technologists from one country to another.

Probably the most important point is to encourage initiative and make it relatively easy for those who wish to do so to move from one country to another, widening their professional experience and exchanging ideas and techniques. Professional bodies have a contribution to make, as have the universities and other educational institutions, but a major responsibility must rest on the Governments even in respect of unorganized and private mobility. Primarily, Government policy will largely determine whether or not financial and other conditions, including pension schemes, are weighted so as to discourage the mobility which is as desirable professionally and from the point of view of science and technology as it is from that of international understanding.

From this point of view the extension of the system of British Commonwealth scientific liaison officers suggested by the Duke of Edinburgh might be as useful as in relation to co-operation in research which he appeared to have primarily in mind, particularly if the system of scientific attachés were extended at the same time. Any increase in the effectiveness with which representations can be made to governments about the conditions which determine the successful prosecution of scientific work are highly desirable. Too often, failure in Government circles, and frequently, too, at lower levels among officials, to appreciate these factors leads to waste of effort and frustration and can even defeat the whole purpose of policies intended to extend scientific or technical activities. The status given to such scientific attachés is important not simply from the point of view of attracting men of the appropriate ability but also from that of the weight likely to be attached to their advice and representations.

The regular exchange of scientific information is a highly technical and complex problem on which the Duke did not touch and which was indeed not fully covered by the Washington Conference last November. There can be little dissent to-day from the view that it is only at the international level that effective solutions are to be found to the problems which arise from the sheer volume of scientific and technical information to-day. Even when all due weight is given to informal contacts as a means of exchanging information, the problem of communication is a fundamental aspect of the joint attack on common problems which the Duke of Edinburgh would like to see and it is also an important part of the work of the Commonwealth Agricultural Bureaux—a system, he suggested, which might be extended to other technologies. How far this is likely to be served by wider membership of research associations and fuller co-operation between them within the Commonwealth may well be a matter for some careful consideration. There are difficulties which stem from political as well as economic considerations but which might disappear in a change of political climate.

The context in which the Duke of Edinburgh discussed these problems was essentially that of promoting the speediest and most effective use of scientific knowledge for human welfare, primarily in the Commonwealth but equally throughout the world. The removal of any obstacles to human intercourse and the communication of knowledge is a first step, for without freedom of discussion and of publication there can be no effective co-operation. The people of the Commonwealth and of the world would indeed benefit by the freest possible movement of scientists, the unhampered exchange of scientific ideas and the removal so far as practicable of linguistic barriers. It is scarcely to be expected, however, that conditions for effective scientific co-operation will be created while obstacles are maintained to the circulation of ideas and of people in other fields of human endeavour, and scientific and technical co-operation should not be treated as a field apart. For the same reason, this establishment of such conditions should, however, precede the extension of any formal system of conferences, whether in relation to the attack on scientific problems or the administration and organization of research.

Science and technology depend largely on the funds placed at their service by the general body of citizens, and co-operation in these fields will only flourish when the essential conditions are sufficiently understood by Governments—and by the citizens who support them—to ensure that adequate funds are forthcoming and appropriate policies pursued. Co-operation in science and technology cannot, therefore, be divorced from consideration of educational issues, and measures directed to improve such co-operation, within or outside the Commonwealth, must include policies designed to raise the standard of general education accordingly. That is only in part, however, a matter of formal education. Much responsibility must rest on professional bodies, and on such bodies as the Parliamentary and Scientific Committee. Any attempt to improve the formal or informal framework of co-operation must be accompanied by a determined effort to enlighten public opinion, both as to what is required and as to the numerous ancillary measures which will make all the difference between the success of such aims and waste of public resources, frustration and even defeat of a calculated policy by sheer ignorance or neglect.

TRENDS IN GERONTOLOGY

A Classified Bibliography of Gerontology and Geriatrics

Supplement One, 1949–1955. By Nathan W. Shock. Pp. xxviii+525. (Stanford, Calif.: Stanford University Press; London: Oxford University Press, 1957.) 120*s*. net.

Experimentelle Alternsforschung

Symposium der Europäischen Abteilung des Biologischen und Medizinischen Forschungskomitees der Internationalen Gerontologischen Gesellschaft, Basel, 4–7 April, 1956. Herausgegeben von F. Verzár. (*Experientia* Supplementum 4.) Pp. 290. (Basel und Stuttgart: Birkhäuser Verlag, 1956.) 34 Swiss francs; 34 D.M.

Ciba Foundation Colloquia on Ageing

Vol. 4: Water and Electrolyte Metabolism in Relation to Age and Sex. Edited by G. E. W. Wolstenholme and Maeve O'Connor. Pp. xii+327. (London: J. and A. Churchill, Ltd., 1958.) 45*s*. net.

Trends in Gerontology

By Nathan W. Shock. Second edition. Pp. viii+214. (Stanford, Calif.: Stanford University Press; London: Oxford University Press, 1957.) 36*s*. net.

THE varied size and contents of this mixed collection of books make it difficult to review them in a connected fashion, but in their different ways the four books provide a general idea of what gerontologists have done, what they are doing, and what they hope to do.

There is not much to say about the Bibliography except to commend its completeness and accuracy (so far as I have been able to check) and to recommend it as a source book to anyone who, whether he calls himself a gerontologist or not, wants to know what work has been done both in the scientific approach to the study of aging and in the medical and sociological care of the elderly.

The next two volumes provide the material presented at symposia held in Basle and at the Ciba Foundation. On the former occasion most of the well-known names in the field were gathered together, and their papers, on the whole, are summaries of their already recognized and accepted contributions to the subject, and of their usual lines of approach to the many-sided topic of the symposium.

Among the 40 contributions (most of them in English or German, but some in French) there are descriptions of the age changes in various metabolic and organ systems to be found in a range of species, discussions of the psychological problems associated with aging, and several more directly geriatric contributions. Perhaps the most unfashionable topic to be discussed was the possibility that auto-intoxication plays an important part in aging. It was refreshing, here, to find a contribution from someone (R. B. Fisher) not usually associated with gerontology, suggesting that the intake of amino-acids in the diet is often too high and that such dietary errors could be disadvantageous to longevity, as well as the paper on more orthodox lines by Korenchevsky.

The subject-matter of the Ciba symposium, the fourth in the series, was confined to water and electrolyte metabolism. On this occasion the contributions by professional gerontologists were fewer, and the immediate relevance of some of the very excellent papers to gerontology rather more tenuous. One finds in the contents of the symposium more an attempt to exemplify the proposition that the age of an organism is an important biological variable which workers in any field must constantly bear in mind. By contrast, the topics discussed at the Basle symposium were more orthodoxly and recognizably gerontological. The Ciba volume gives the full transcript of the discussions which one has come to expect and to profit by. One gets a much clearer impression of a vital and interested meeting when one compares it with the much more scrappy transcript of the discussion in Basle.

The last of the quartet is a second edition of the book first published in 1951. The changes and the extent of development in the subject in the past eight years are very evident when one compares the virtually new chapters which Dr. Shock has had to write with the old ones. Dr. Shock confines his attention mainly to American experience and begins with a detailed statement of the economic and sociological facts—of age distribution of the population, employment, income, health services—which make a better understanding of aging processes such a compelling need. Subsequent chapters provide short abstracts of the sorts of work in the field which are going on all over the world. The scope of these chapters has extended very considerably since the first edition, but the method of stringing together short abstracts of individual programmes of work leaves one with a sense of piecemeal approach to the problem rather than a concerted attack.

There is so much change and new work in Dr. Shock's book so far that it is all the more surprising to find that his last chapter on plans for the future, where he outlines his ideas of how research in gerontology should be fostered, is unchanged. Dr. Shock proposes the setting up of a large-scale research institute, and details the way the proposal should be organized. His proposals do not really convince that this is the best way to foster the subject. The papers, at the Ciba symposium especially, reveal how frequently the parameter of age comes into all sorts of investigation and suggest that the advancement of gerontology as a reputable scientific subject now depends more on the interest that can be aroused among workers in all fields of biological study than on the provision of specialist institutes.

P. L. KROHN

AN INTRODUCTION TO ELECTRONIC THEORY

Electronic Theories of Organic Chemistry

An Introductory Treatment. By John William Baker. Pp. viii+224. (Oxford: Clarendon Press; London: Oxford University Press, 1958.) 30*s*. net.

THIS book, which is described as an introductory treatment to electronic theories of organic chemistry, is a welcome addition to the growing number of text-books now available in this field. The subject has become a well-established and indeed integral part of the teaching of organic chemistry, and it is opportune that a simple account should be available by an author who has made important contributions to it. The nomenclature and conventions follow those of the British school and more particularly of Sir Christopher Ingold and his collaborators, and the examples cited as well as the argument are drawn almost entirely from their work. This book itself follows closely the arrangement of the larger work by Ingold, including some diagrams and tabulated matter from the latter's book.

The material included comprises all the basic considerations of reaction theory, the classification of reagents as nucleophilic or electrophilic, the molecularity of reactions and the nature of various classes of rearrangements. In addition, some of the physical evidence for the existence of electron displacements, as well as a qualitative description of the quantum theory of valency, is included. Each topic is carefully and concisely explained and accompanied with appropriate examples. The book is adequately indexed.

Such criticisms as I have to offer are of a minor nature. As the author points out, Fig. 1, on p. 35, is not an adequate representation of an electronic charge-cloud. It is rather unfortunate, therefore, that some other device was not adopted the better to demonstrate the charge distribution ; particuarly in an introductory text-book such as this. Secondly, the evidence for the direct linking of the carbon–sulphur bond in bisulphite addition products may now be considered well established as a result of isotopic studies, Raman and ultra-violet spectra. This might have been made clearer in the discussion of these compounds (p. 121).

The book is well produced, as may be expected of the Oxford University Press. The lettering and the diagrams are clear and well distributed. The text is, moreover, remarkably free from casual errors, the only one that I have noticed being a missing 'h' on p. 168.

This book is to be recommended as an authoritative account of its subject-matter and one which will well repay an attentive study. The demands the book makes on a previous knowledge of structural organic chemistry may be a little severe for any but the most advanced sixth-form schoolboys, but should be within the capacity of the other readers for whom it is intended.

R. I. REED

ECONOMICS OF TELECOMMUNICATION

Telecommunication Economics

By T. J. Morgan. Pp. 452. (London: Macdonald and Co. (Publishers), Ltd., 1958.) 50*s*. net.

IF the difference between 'pure' science and engineering could be expressed by a single word, that word would well be 'economics'. Yet the amount of economics which enters into the basic training of most professional engineers is still very small. Of all branches of engineering, surely telecommunication is one of which the social, economic function is most apparent (the very word 'communication' means 'sharing'), for its primary function is to widen relationships between people, extend the speed of their actions, of their trade and business. But there are very few text-books of telecommunication suitable for students which even touch upon the economic aspects, and this thoroughly readable work will be very welcome.

The author, Mr. T. J. Morgan, is a member of the planning staff of the Post Office, which well qualifies him to write this book, having extensive experience of large-scale planning, both in Britain and elsewhere. He recognizes the relative poverty of economic studies among engineers by wisely starting his book with an apology for attempting their enrichment, continuing with an elementary account of the general principles of economics, and adding a chapter on the mathematics of statistics and probability. An excellent bibliography provides a list of texts for further detailed reading in these fields.

The influence of economic principles upon the planning and operation of large-scale telecommunication systems is gently introduced to the student, by first stressing that all engineering plant has a finite life and requires regular outlay for upkeep and operation, in addition to initial capital cost, so dictating a certain minimum utility, charges, justified development and additions, etc. ; this material is well illustrated by examples and is extended to include considerations of forecasting of future needs.

More sophisticated and specialized aspects are treated in detail, including the economics of manual and of automatic exchanges, of various types of transmission, of buildings and other ancillary structures, of traffic routing and many others.

The book is well indexed and provided with extensive references, with tables of data and illustrations. It will be welcomed by professional engineers and may well serve as a text-book for college students.

COLIN CHERRY

PROGRESS IN VITAMIN AND HORMONE RESEARCH

Vitamins and Hormones

Advances in Research and Applications, Vol. 16. Edited by Prof. Robert S. Harris, Prof. G. F. Marrian and Prof. Kenneth V. Thimann. Pp. xi+437. (New York: Academic Press, Inc.; London: Academic Books, Ltd., 1958.) 11.60 dollars.

THIS book contains nine review articles, three of them dealing primarily with nutritional matters, five of them mainly concerned with hormonal affairs, and one, entitled "The Dependence of Gonadal Function upon Vitamins and other Nutritional Factors", by C. Lutwak-Mann, with both. In this article Dr. Lutwak-Mann ranges widely and engagingly, discussing not only mammals but also birds, amphibians, fishes, marine invertebrates, and insects and trematodes. An article which extends its interest from the queen substance in honey-bees to the diet of Charles Dickens's Oliver Twist cannot fail to stimulate.

The discussion of "Nutritional Effects of Parasitic Infections and Disease", by Q. M. Geiman, is another interesting treatment of a subject ripe for review. Dr. E. E. Snell opens his article on "Chemical Structure in Relation to Biological Activities of Vitamin B_6" by posing the general question of specificity of structure and function of physiologically important compounds, and referring to the fact that any alteration in the structure of pantothenic acid diminishes its vitamin activity although, so far as we now know, the functional portion of coenzyme *A* is not present in the pantothenic acid part of the molecule. He then poses the arresting question : "Is the specificity in structure merely a developmental accident, a genetic fixation upon a useful compound that happened to be present when life first arose ?" He examines in an authoritative manner such questions in relation to pyridoxamine, pyridoxal, and their chemical relations, substances in which, as he points out, a knowledge of the relationship of structure to function is more extensive than for that of any other vitamin.

The great interest at present shown in the origin of cardiovascular disease is illustrated by the review "Vitamins and Other Nutrients in Cardiovascular Disease", by W. C. Felch, L. Sinisterra, T. B. Van Itallie, and F. J. Stare, and also by that on "Hormonal Aspects of Coronary Artery Disease", by M. F. Oliver and G. S. Boyd. "The Physiology of Secretin" is ably reviewed by M. I. Grossman, while the "Chemistry and Physiology of the Thyroid-stimulating Hormone" is discussed by M. Sonenberg. In the chapter on "Glucagon", by O. K. Behrens and W. W. Bromer, the biology and the chemistry of glucagon are succinctly surveyed, and the concluding article, entitled "Synthetic Derivatives of Cortical Hormones", by J. Fried and A. Borman, includes a consideration of the synthesis and biological activities of eleven different types of artificially produced chemical relation of the naturally occurring adrenal cortical hormones.

The book includes a cumulative index for Volumes 11–15 of "Vitamins and Hormones", which is shorter and more compact than the two previous cumulative indexes, and adequate author and subject indexes for Volume 16.

This volume should be of interest to biochemists, physiologists, to medical men, and to biologists in general, as well as to those whose interest is mainly in the chemistry of substances of biological importance. Without exception, the articles are authoritative and well written.

BIOCHEMICAL ANALYSIS

Methods of Biochemical Analysis

Vol. 6. Edited by Prof. David Glick. Pp. ix+358. (New York: Interscience Publishers, Inc.; London: Interscience Publishers, Ltd., 1958.) 8.50 dollars.

THE sixth volume of this valuable series contains ten contributions. The first two are concerned with the determination of nucleic acids; chemical means are dealt with by J. M. Webb and H. B. Levy, and microbiological assay methods by H. K. Miller. Both contributions describe a number of different methods and both sets of authors are confident that reliable results can be obtained when these methods are applied to suitable starting materials. However, there are warnings that care must be taken if either type of analysis is applied to material of a new type and it is suggested that a new material should initially be analysed by at least two independent methods.

Formaldehyde and serine estimations are described by W. R. Frisell and C. G. Mackenzie, and purine analysis by F. Bergmann and S. Dikstein, who describe the relatively new mercury salt procedures.

Serotonin and related compounds are considered by S. Udenfriend, H. Weissbach and B. B. Brodie, who include related indoles and also the preparation and assay of enzyme systems related to serotonin metabolism. They conclude with a short section on related drugs and also include an interesting account of spectrophotofluorimetric analysis.

A determination which is now becoming of great clinical importance is transaminase, which is described by A. J. Aspen and A. Meister. A variety of procedures are included, although the section is orientated more towards the classical analysis of enzymes in tissue preparations rather than the rapid simple serum methods which to-day are used by many more laboratories.

N. S. Radin contributes a section on glycolipide determination which has valuable sections on the extraction and handling of these compounds which may be unfamiliar to workers in other fields. He also describes details of the laboratory techniques which he has found advantageous, and these are applicable also to any type of work which involves the quantitative handling of small volumes of volatile organic solvents.

The determination of thiamine by animal and microbiological assay and by chemical methods, including the well-known thiochrome technique, is described by O. Mickelson and R. S. Yamamoto. A. Kolin describes his elegant techniques of electrophoresis combined with physical gradients and shows a number of examples of the separations he obtained. Finally, S. Gardell describes hexosamine determination. His contribution and the purine chapter are the only ones by non-American authors.

The production and appearance of the volume are of the standard which we associate with Interscience Publishers.

SCIENCE AND TECHNOLOGY OF RUBBER

British Compounding Ingredients for Rubber

Compiled by Brian J. Wilson. Pp. xx+528. (Cambridge: W. Heffer and Sons, Ltd., 1958. Published for the Research Association of British Rubber Manufacturers.) 60*s*. net.

Rubber

Fundamentals of Its Science and Technology. By Dr. Jean le Bras. Translated by Dr. Irene E. Berck. Pp. 464. (London: Crosby Lockwood and Son, Ltd., 1957.) 65*s*. net.

Chemistry of Natural and Synthetic Rubbers

By Prof. Harry L. Fisher. Pp. vii+208. (New York: Reinhold Publishing Corporation; London: Chapman and Hall, Ltd., 1957.) 52*s*. net.

TWO of these three books have been written by authors connected with national research organizations. The third has been written by an author well known for his contributions to rubber chemistry.

The books of le Bras and Fisher are eminently readable and can be perused with pleasure even by those who have spent many years in the study of rubber. They are to rubber men what such a book as Lachmann's "Spirit of Organic Chemistry" was to organic chemists of the past generation.

Wilson's book, however, is essentially a reference book similar to that published in France several years ago by Jacobs. It is limited to British products; but this has not the restricting influence that one might at first expect since so many foreign producers have associated organizations within the British Commonwealth. This book has four main sections on compounding ingredients for natural and synthetic rubbers; compounding ingredients, processing and modifying agents for natural and synthetic latices; special-purpose products such as mould lubricants, anti-tack agents, etc.; and indexes of manufacturers and trade names. The book has been produced with the thoroughness and reliability which one has come to expect from the Research Association of British Rubber Manufacturers. It is a book which no rubber manufacturer can afford to be without.

"Rubber: Fundamentals of its Science and Technology", by le Bras, is a masterpiece of conciseness. It covers the whole field of rubber in less than 500 pages. The diagrams are fascinating and carefully designed and with few exceptions explain the apparatus or plant without the necessity of referring to the text. The first four chapters are particularly excellent, and reflect the author's life-study of natural rubber. From its very size and coverage it is obviously not a reference book, and the limited references at the end of each chapter must be regarded as the personal selections of the author and not necessarily the most important. It can be recommended to students of rubber technology who have a basic knowledge of chemistry and who have already read the exhaustive treatises on particular fields as a 'refresher' before taking their examinations.

"The Chemistry of Natural and Synthetic Rubbers", by Fisher, covers, as can be judged from the title, a narrower field. It can be recommended to those rubber technologists who already possess a sound knowledge of organic chemistry. Unlike the previous book by le Bras, the chapters on synthetic rubbers are more thorough than those on the natural product. The book is essentially descriptive, and where the author has dealt with the theory behind the facts it can be taken that the most modern views have been given; for example, free radical mechanism is given as the basis of the attack on rubber by oxygen. In addition to its practical use to the young student of rubber technology, it is a book which can be read with pleasure by those to whom the facts contained in it are already known.

W. J. S. NAUNTON

TO VIEW OR NOT TO VIEW?

Television and the Child

An Empirical Study of the Effect of Television on the Young. By Hilde T. Himmelweit, A. N. Oppenheim and Pamela Vince. Pp. xix + 522. (London: Oxford University Press, 1958. Published for the Nuffield Foundation.) 42*s*. net.

THE widespread interest aroused by this report is easily understood. It is the first study of its kind to be conducted among English-speaking peoples and, indeed, probably in the world. Unlike so many other pronouncements about the effects of this popular new medium on children, it is truly a scientific survey conducted on a large enough scale to make its findings weighty and authoritative. It should, for example, cause many school medical officers to hesitate before they include in their annual reports pontifical and unsubstantiated judgments about the harmful effects of television on children's eyes, posture and behaviour.

The report is of value not only for the observations it makes but also for the deductions which may be made from them. Among the more cheering conclusions is that children of healthy interests and appetites seldom become addicted to television and that there are comparatively few children who do. Nor do children view continuously from the time they get home from school until they go to bed. Most children view selectively and exercise a good deal of discrimination; working-class children do not view more continuously than those from the middle-classes. In general, television does not cause listlessness, loss of sleep, bad dreams, lack of concentration, or eye strain. Children are not made more passive or become more aggressive, or kept away from youth clubs by television.

Against this are a number of conclusions which, on balance, suggest that television, as at present administered, has more harmful than beneficial influence on children. Most viewing by children is done up to 9 p.m. and, since the introduction of the second channel, is done by switching from channel to channel to find their favourite programmes. These programmes often consist of plays or playlets which, while differing superficially, show much uniformity in the values and stereotypes which they present and have a slow but cumulative effect on the outlook of the child viewer. Since the world of television drama tends to be that of upper middle-class urban society, the occupations of people of this level are depicted as worth while, whereas manual work is presented as uninteresting. Although television plays teach that self-confidence and toughness are needed to achieve success they also show that goodness of character is not enough; that life is difficult, especially for women; that marriages are frequently unhappy, and parent-child relationships often strained. Events rarely turn out satisfactorily, and virtue seldom brings happiness in its train. Violence is an inevitable part of life, and good people often resort to it. For the adult observer a hackneyed view of life emerges, similar in many ways to that offered in the cinema or theatre; for the child television may afford a glimpse of adult life which he would otherwise gain less often and only at a later age. What television can do is indicated by the conclusion that, probably as a result of B.B.C. programmes about foreign (and especially European) countries, viewers made fewer value judgments about foreigners; where stereotypes were given, they tended to reflect those offered by television.

All in all, the values of television can make an impact if they are consistently presented in dramatic form, and if they touch on ideas or values for which the child is emotionally ready. Extrapolating from these findings, one would expect that in crime and detective series the constant display of aggression by both the criminal and the upholder of the law would also make an impact on those children sensitized to such cues.

The main recommendation made by Dr. Himmelweit and her colleagues is that the B.B.C. and I.T.A. must collaborate much more over the balance of programmes; worthwhile programmes should go out on the air at the same time. They also recommend that producers should be supplied with more information about the effects of programmes on their audiences. Here the Granada Television Company should be commended for its initiative in sponsoring a fellowship at the University of Leeds to examine the impact of programmes on audiences.

What the authors do not openly recommend is that before the Government authorizes the use of a third channel, the B.B.C. and I.T.A. should prove themselves worthy trustees. The I.T.A. particularly would need clear direction and close supervision before it could be entrusted with a task which all its previous performance suggest it is unfitted to perform.

Parents and teachers who read this report would do right to insist on substantial guarantees.

Gem Testing

By B. W. Anderson. Sixth edition, revised and reset. Pp. 324. (London: Heywood and Co., Ltd., 1958.) 42*s*. net.

A CENTURY ago the identification of gemstones was the speciality of experts in the trade who, by long experience and from lore handed on from masters to apprentices, had learned to judge their gemstones by sight and touch with little beyond a lens and perhaps a file to help them. The use of simple scientific methods for determining density and the optical characters of gemstones as a means of identification had long been advocated by a few enthusiasts but not generally adopted. It was not until the appearance on the market of synthetic rubies, sapphires and spinels that the scientific methods began to gain more general acceptance. New methods had to be devised to distinguish natural from synthetic stones and, later, to distinguish cultured pearls from natural ones. The London Chamber of Commerce set up a laboratory for testing diamonds, pearls and precious stones, the Gemmological Association of Great Britain was founded, and lecture courses on gemmological subjects were commenced. The author of this book is the head of the laboratory and for many years he has taught and examined for the Association. His book is the best on this subject, and in the sixth edition there is much that is new.

The author is a strong advocate of the use of a direct-vision spectrometer for identification of gemstones by their absorption spectra, and the chapter on this part of the subject has been largely re-arranged and illustrated.

A neat method of comparing the refractive indices of a number of gemstones is described. It depends on observing, or photographing, the shadows the stones throw when immersed in a liquid with a refractive index near their own while illuminated from above. The use of a contact photograph and ultra-violet light can be made to show at a glance the difference betweeen natural and synthetic rubies,the latter being definitely more transparent to ultra-violet light. More use is being made of the study of inclusions in gemstones, a branch of the subject extensively studied by Dr. E. Gübelin of Berne. Many of his photomicrographs of inclusions are used in this book.

These are only a few of the tests the author describes. W. CAMPBELL SMITH

Behavior and Psychological Man

Essays in Motivation and Learning. By Prof. Edward Chace Tolman. Pp. xiv+269. (Berkeley and Los Angeles: University of California Press; London: Cambridge University Press, 1958.) 1.95 dollars; 17*s*. 6*d*.

THIS volume is a reprint of Tolman's "Collected Papers in Psychology" first published in 1951 and it includes a warm and appreciative foreword by his colleagues at the University of California. The papers have been chosen to indicate the successive stages in the development of Tolman's theoretical system.

Prof. Tolman's contributions to psychological theory and experiment are equally outstanding. This will be granted without necessarily sharing his views. He is the exponent of 'molar' behaviourism, in contrast to the 'molecular' behaviourism of the school of Clark Hull at Yale; and he has gone further than any other behaviourist in trying to embrace within his system essential features of *Gestalt*, psychoanalytic, and hormic theory in terms of operationally defined variables.

The considerable achievements of Prof. Tolman mark a characteristic phase in the development of psychology. His experimental work, however, must be disentangled from its theoretical framework. The latter rests on a positivistic philosophy the validity of which is not self-evident. Indeed, it would seem that the behaviouristic positivism pursued by Prof. Tolman in the interests of scientific rigour has, in fact, been detrimental to the psychological 'all-inclusiveness' to which his system aspires. JOHN COHEN

The Excitable Cortex in Conscious Man

By Dr. Wilder Penfield. (The Sherrington Lectures, 5.) Pp. ix + 43. (Liverpool: Liverpool University Press, 1958.) 10*s*. 6*d*. net.

THIS book presents a summarized version of the data which the author has accumulated from the responses to electrical stimulation of the cerebral cortex during operations on the human brain. It also elaborates the author's hypothesis of a 'centrencephalic system' within the brain, concerned with higher integrative processes. The sensations which patients describe when the visual, auditory or somatic sensory area of the cortex is stimulated, are discussed, together with the movements elicited by stimulation of the motor cortex. The effects of stimulation of the temporal lobe, particularly psychic responses, are dealt with in more detail and in relation to temporal lobe epilepsy. The author points out that the clinician must contribute to science "as best he can from very different material and as chance presents it". Certainly he appears to have made good use of the material available to him in his long experience as a neurosurgeon.

While the book contains little that is not available in the other writings of this author, it presents this material in a very acceptable form, well illustrated, and with clinical examples. It should be easily understood by those with little knowledge of neurology and to the student it provides a useful introduction to this field of research. P. B. BRADLEY

Information Service in Libraries

By D. J. Foskett. (Crosby Lockwood's New Librarianship Series.) Pp. vii+142. (London: Crosby, Lockwood and Son, Ltd., 1958.) 13*s*. 6*d*. net.

IN this little volume Mr. D. J. Foskett presents a concise but thoroughly competent survey of the development of information service in libraries and the various aspects of that work to-day, as well as the qualifications demanded of those who carry such responsibilities. To anyone contemplating such a career he offers much sound advice, while to those already occupying posts as information officers or as librarians he indicates problems where further thought and much closer co-operation are needed. Mr. Foskett does not hesitate to express his own opinions or preferences; but his point of view is always reasonably argued and it is incidentally rather than by direct attack that he shows how trivial is the attempt to draw a division to-day between the librarian and the information officer or between the handling of scientific and technical literature or any other form of literature. The bibliographies appended to his several chapters are adequate and balanced, and this book should both provoke useful debate and help the beginner to master his profession. R. BRIGHTMAN

NON-FLAGELLAR APPENDAGES OF BACTERIA

By Dr. CHARLES C. BRINTON, jun.

Laboratoire de Biophysique, Institut de Physique, Université de Genève,
and Department of Biophysics, University of Pittsburgh

BACTERIAL pili (Latin, hair or fur) are recently discovered filiform appendages found growing from the surface of many different species of bacteria. They are thinner, straighter, and more numerous than flagella (Fig. 1) and have a uniform diameter of about 80–100 A. They are only visible in the electron microscope, and have been independently observed by several workers[1,2]. The first detailed study of pili, by my colleagues and me[3], demonstrated the existence of two distinct phases within one bacterial strain, piliated and non-piliated, distinguishable from each other either in the electron microscope or by microscope electrophoresis, the electrophoretic mobility of the piliate cells being about half that of the non-piliate cells. Each phase could spontaneously change into the other at a rate of the order of 10^{-3} per bacterium per division. The pili were fragile and could be removed almost entirely by mechanical agitation in a high-speed mixer (Fig. 2). The electrophoretic mobility of these depiliated bacteria was nearly the same as that of the non-piliate form; but, in a few minutes, the mobility decreased to its original value, indicating re-growth of the pili. Cell-free filtrates of piliated bacteria could apparently inactivate the even-numbered *T*-phages. Maccacaro and Angelotti[4] investigated the distribution of piliation in eleven strains of *Escherichia coli K*-12 having various combinations of genetic markers for fermentation, nutritional requirements, antibiotic resistance and bacteriophage resistance, and confirmed the existence of distinct piliate and non-piliate forms but observed no definite correlation between piliation and any of the above genetic markers.

Duguid *et al.*[5,6] surveyed a large number of bacterial strains of different genus and species for the presence of pili, and found piliation in most strains of *E. coli*, *Shigella flexneri*, *Salmonella*, *Klebsiella*, *Proteus*, *Chromobacterium prodigiosum* and *Bacterium cloaceae*. The ability to adhere to and agglutinate red blood cells was most often associated with piliation, although a few piliate strains could not agglutinate and some non-piliate strains could. These authors also confirmed the phenomenon of spontaneous reversible change between the piliate and non-piliate phases. Gillies and Duguid[7] prepared high-titre antisera against piliate strains of *Shigella flexneri* which agglutinated them and also inhibited their hæmagglutinating activity. A cross-reaction with *E. coli* was demonstrated.

Pili have been called by several different names: 'fine threads'[1], 'bristles'[8], 'fimbriæ'[5–7], and 'filaments'[2–4,9]. It is felt that the word 'pilus' is the most descriptive term, since the pili usually cover most of the bacterial surface and are continually growing out in a manner quite analogous to hair or fur.

The present article is a summary of results of investigations on the genetics, biological activity, chemistry, and electrophoresis of pili carried out during the past three years at the Biophysics Departments of the University of Geneva and the University of Pittsburgh. This work will be published elsewhere in detail.

Genetics

Quantitative genetic analysis has been greatly facilitated by the discovery that the piliated phase of *E. coli* forms smaller and smoother colonies (Fig. 5) on solid media than the non-piliated form[10]. This distinctive colonial difference has been found to exist for all piliate strains of *E. coli* examined so far. Conversely, that a colony difference means a difference in piliation, does not hold; rough and smooth colonial forms of the same strain can exist in the absence of any piliation. A relative count of piliate and non-piliate forms was made on the same suspension of *E. coli B* strain *L*(*E*) by three independent methods: (*a*) electron microscope count of morpho-

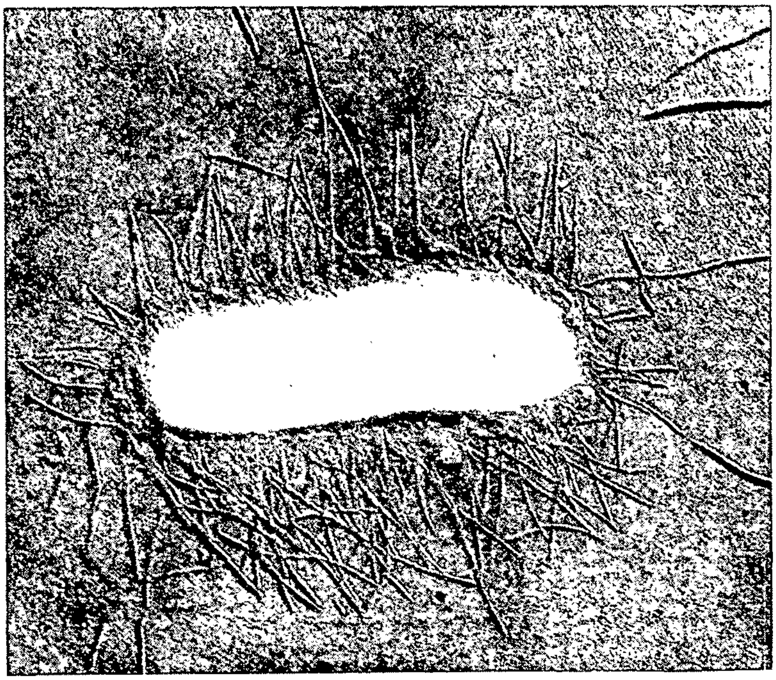

Fig. 1. A piliated bacterium growing on a collodion membrane overlying a nutrient agar base. Spheroidal surface material can be seen on or near the organism. Strain *E. coli B*-*L*(*E*)P^{+}

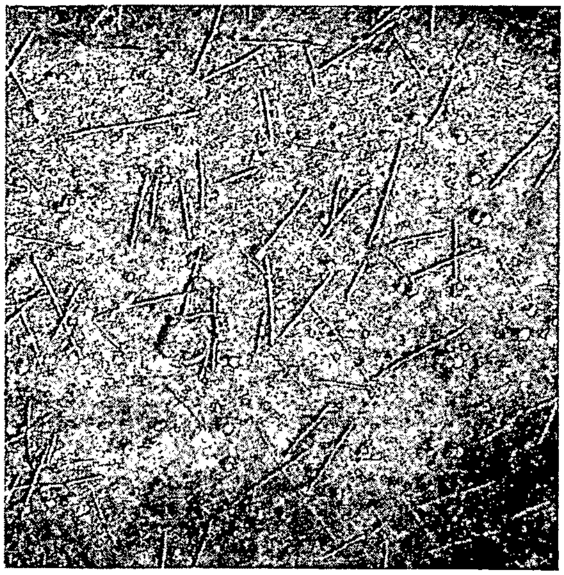

Fig. 2. Electronmicrograph of crude preparation of pili obtained by shaking a culture of piliated bacteria and centrifuging out the deflamented organisms

logically piliate and non-piliate forms; (*b*) electrophoretic count of 'fast' and 'slow' organisms; and (*c*) colony count of smooth and rough colonies. The averages of nine relative counts by each of the three methods were the same within an experimental error of 3 per cent. All three methods clearly distinguish between two distinct forms: completely piliate ($P+$) or completely non-piliate (P^-); if intermediate forms exist, they are rare. 14 of 19 strains of *E. coli B* and *E. coli K*-12 were found to possess the potentiality for piliation. It is quite possible that the remaining 5 strains also had this capacity, but that the P^- phase was dominant under the cultural conditions of the survey (aerated tryptone at 37°).

In order to obtain more basic, quantitative information, a single strain, *E. coli B*, *L*(*E*), was chosen for investigation because of its rich piliation (Fig. 1) and clean-cut difference between $P+$ and P^- colonies (Fig. 5). A 99·9 per cent pure $P+$ culture was prepared by inoculating a single smooth colony into aerated tryptone and growing to 10^8 organisms/ml. at 37°. From this culture, parallel tubes at 37° were inoculated with an average of 0·3 organisms per tube, which guaranteed that most of the tubes which eventually showed growth started from one or two bacteria. The fraction of non-piliate organisms, *f*, was followed as a function of time in each tube showing growth, and typical results are plotted in Fig. 6. The bacterial concentration was maintained in the neighbourhood of 10^8 organisms/ml. by dilution.

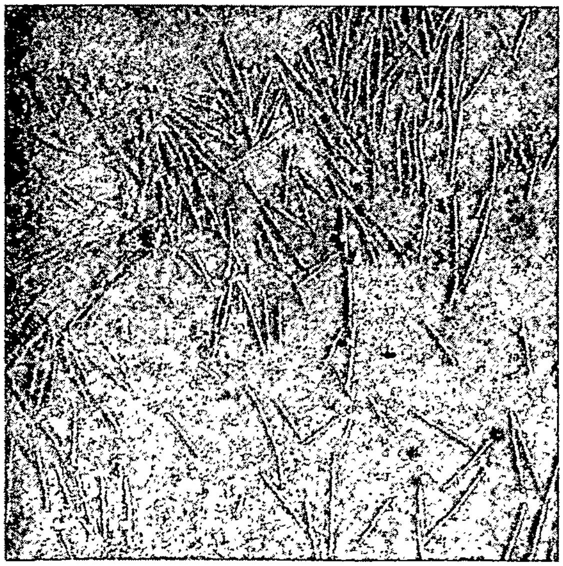

Fig. 3. Sample of pili taken from faster electrophoretic component

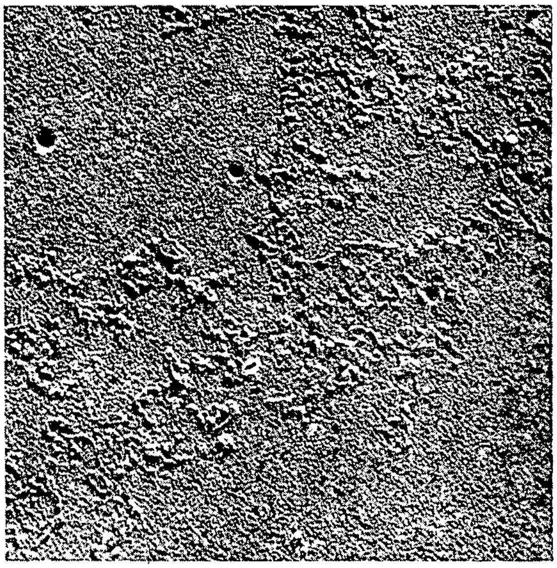

Fig. 4. Sample of spheroidal surface material taken from slower electrophoretic component

The shapes of the curves in Fig. 6 can be explained by assuming that the rate of the $P+ \rightarrow P^-$ 'mutation' (in the formal sense of a sudden, inheritable change having a constant probability per organism per division) is about 4×10^{-4} per bacterium per generation, the reverse mutation-rate is negligible and the $P+$ phase has a generation time about 10 per cent greater than the P^- phase. As soon as enough P^- bacteria have arisen by mutation they rapidly take over the culture because of their higher growth-rate. The theoretical statistical distribution for the average number of mutants per culture in a series of parallel cultures has been derived by Armitage[11]. For the case of no back mutation and unequal growth-rates of parent and mutant, equations 70 and 71 of Armitage may be used. The theoretical means of values of *f*, calculated assuming a mutation-rate of $\alpha = 4 \cdot 3 \times 10^{-4}$ and generation times of $t_p + = 32 \cdot 2$ min. and $t_p - = 29 \cdot 0$ min., is plotted as a function of number of generations in Fig. 6. These numerical values were assumed in order to fit the experimental data; however, the validity of this model is borne out by independent measurements of the mutation-rate and the growth-rates.

The $P+ \rightarrow P^-$ mutation-rate was determined by the 'zero-point' method, which is independent of any selection due to differences in growth-rate. The entire contents of parallel $P+$ clones were plated out when the clones contained an average of about 1,000 cells and the fraction of clones containing no P^- colonies was determined. The mutation-rate as

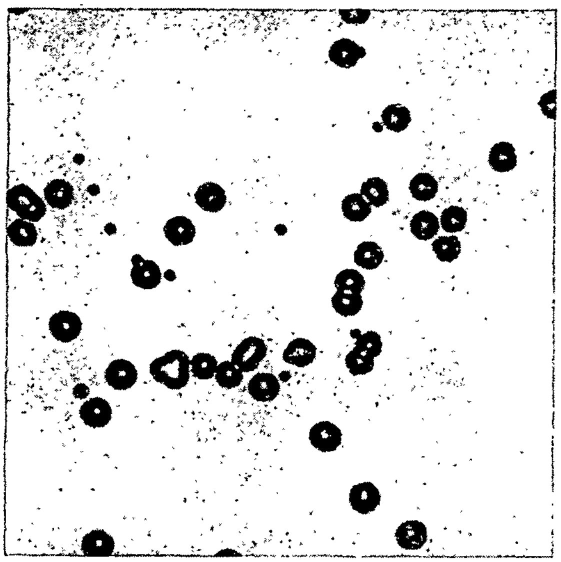

Fig. 5. Colonies of *E. coli B-L(E)* growing on nutrient agar. The larger, rougher colonies are the non-piliated form (P^-) and the smaller, smoother colonies are the piliated form (P^+)

given by the formula $\alpha = -\ln P/N$, where α is probability of mutation per bacterium per division[12], P is fraction of clones having no mutants, N is average total number of cells in the clones, was $3{\cdot}8 \times 10^{-4}$, which is in good agreement with the rate estimated from Fig. 6. The variance of the distribution of numbers of $P-$ mutants in parallel clones is approximately equal to the theoretical variance calculated from equations 70–74 of Armitage[11], which were derived from the hypothesis of spontaneous mutation.

The mutation-rates at four different temperatures were determined by the zero-point method and are plotted in Fig. 7. For a 10-deg. rise in temperature, the mutation-rate decreases by a factor of 10.

The generation times of the two pure phases in tryptone at 37° as determined by colony counts, and optical density measurements were found to be $P+$: 30·5 min. and $P-$: 29·0 min. When pure $P+$ and $P-$ cultures were mixed and grown at 37°, the fraction of P^- organisms increased with the slope expected from the differential growth-rate. The relative growth-rate of the $P+$ and $P-$ phases was also found to be dependent on temperature. In Fig. 8 the ratio of the $P+$ generation time to the $P-$ generation time is seen to decrease with temperature, passing through 1·0 at about 41°. When a mixture of $P+$ and $P-$ cultures was grown at 42°, the fraction of $P-$ cells in the culture decreased as expected.

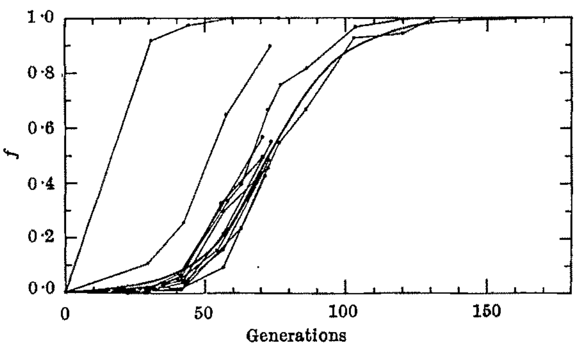

Fig. 6. The $P^+ \rightarrow P^-$ mutation in aerated tryptone at 37°. Points for individual cultures are connected by thin straight lines; the heavy smooth curve is the theoretical one calculated from Armitage's equations (ref. 11)

The dependence of mutation-rate and relative growth-rate on temperature shown in Figs. 7 and 8 formed the basis of methods for growing and maintaining pure $P+$ and $P-$ cultures. Pure $P+$ cultures were obtained by plating out a mixed culture and incubating at $> 41°$, picking a single smooth colony, and inoculating into broth with incubation at $> 41°$. Pure $P-$ cultures were obtained by inoculating a single rough colony and incubating at any temperature, since the $P- \rightarrow P+$ mutation has not been observed in this strain.

Strain $L(E)$ is somewhat anomalous in that the $P+ \rightarrow P-$ mutation is not readily reversible as in some other strains. Temperature effects on the stability of $P+$ and $P-$ forms have been observed in other strains. All genetic experiments were carried out in aerated tryptone; mutation- and growth-rates may be different in other media.

Electrophoresis

The electrophoretic mobility of piliate and non-piliate bacteria and of pili free in solution has been

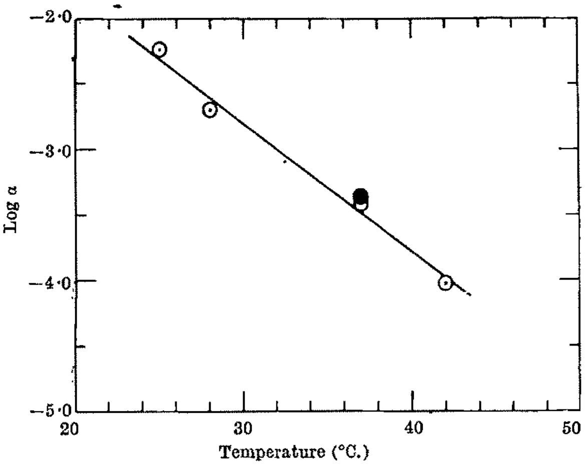

Fig. 7. The $P^+ \rightarrow P^-$ mutation-rate, α, as a function of incubation temperature. Open circles, experimental points; solid circle, value of α used for plotting the theoretical curve of Fig. 6

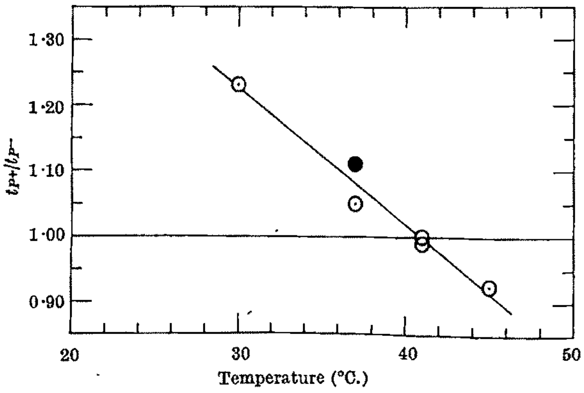

Fig. 8. Relative generation time, t_{P^+}/t_{P^-}, of P^+ and P^- bacteria as a function of temperature. Generation times were determined separately on pure or almost pure P^+ or P^- cultures both by optical density measurements and colony counts. The experimental points are the open circles; the solid circle is the point calculated from the values of t_{P^+} and t_{P^-} used to plot the theoretical curve of Fig. 6

determined as a function of pH and ionic strength. Over a wide range of pH (6–11) and ionic strength (0·0003–0·1000) the mobility of free pili is the same as the mobility of piliated bacteria, demonstrating that the mobility of piliated cells is determined solely by the pili. This means that calculations of the average surface charge density cannot be made using the usual equation employed for bacteria and cells valid only for flat, smooth surfaces ($\varkappa a > 100$)[13]. The radius of curvature used in the charge density equations must be at least as small as the 40–50 A. radius of the pili.

The forms of the salt concentration–mobility curves for the $P+$ cells and the P^- cells in acetate buffer are almost identical to the curves obtained by Moyer[13] for smooth and rough strains of *E. coli* and by Stearns and Roepke[14] for smooth and rough strains of *Brucellus abortus*. In all three cases, the smooth-colony form had the lower mobility.

When a culture of $P+$ bacteria is mechanically agitated in a high-speed mixer for 2 min. and the cells centrifuged out, a suspension of free pili and 'spheroidal surface material' is left behind (Fig. 2). The free boundary electrophoresis pattern of this suspension shows two distinct, homogeneous peaks. When samples of each component were examined in the electron microscope, the leading boundary sample was almost pure pili (Fig. 3) and the trailing boundary sample was pure spheroidal surface material (Fig. 4). The spheroidal surface material in Fig. 4 appears somewhat degraded compared with that shown in Fig. 2; this is possibly due to the high pH ($pH = 10·3$) used in this particular electrophoresis run. Free boundary electrophoresis provides a useful method for the separation of these two components, which is difficult by centrifugation or isoelectric precipitation.

Biological Activity

The cell-free culture fluid of shaken $P+$ cultures of *E. coli B–L(E)* has at least three biological activities: agglutination of red blood cells, inactivation of certain bacterial viruses, and antibiotic activity against another strain of bacteria (colicine *E* activity)[15]. The identification of these three activities with the two morphological components has been investigated.

Hæmagglutinating activity was measured by the ability to cause visible aggregation in small glass tubes of 0·2 per cent chicken red blood cells. A cell-free culture fluid prepared from piliate bacteria and concentrated about 1,000 times by isoelectric precipitation gave a hæmagglutination titre of 10,240; unconcentrated fluid gave a titre of 8. Pili from broth-grown $P+$ bacteria had about 30 times the hæmagglutinating activity of pili from bacteria grown in synthetic medium (*M*9). An agglutination test of electrophoretically separated pili and spheroidal surface material showed that all the activity was associated with the purified pili and none with the spheroidal surface matter. This is the first demonstration of hæmagglutinating activity associated with free pili; 0·5 μgm./ml. of this preparation was sufficient to give a positive test. Other convincing evidence that the pili themselves are the organs of hæmagglutination rather than some other material produced by piliate organisms was obtained. Low concentrations (1 bacterium per blood cell) of pure $P+$ cultures will hæmagglutinate while very high concentrations (1,000 bacteria per blood cell) of pure $P-$ cultures will not[10]. When the pili are removed from solution by centrifugation, isoelectric precipitation, or ammonium sulphate precipitation, the hæmagglutinating activity is also removed.

Anti-viral activity[3,16] was measured by mixing cell-free culture fluid with bacteriophage *T*2 and assaying for phage as a function of time by the plaque count method. Unconcentrated cell-free culture fluids of both $P+$ and $P-$ cultures showed the same activity (6 per cent survival after 60 min. at 37° of an initial phage concentration of 10^8/ml.), demonstrating independence of anti-viral activity and pili. The activity of electrophoretically separated samples showed most of the anti-viral activity to reside in the spheroidal surface material fraction and very little in the pili fraction. Electron microscopy of a mixture of phage *T*2 and cell-free $P+$ culture fluid shows the phage particles adsorbed to the spheroidal surface material and no apparent association of pili with the phage. The spheroidal surface material is only active against the even-numbered *T*-phages.

Colicine activity was measured by adding a strain of *E. coli* sensitive to killing by colicine *E* (strain 'Rowley') to various dilutions of cell-free culture filtrate and incubating for 30 min. at 37°, then plating on solid medium. The last dilution showing at least 50 per cent inactivation of the indicator strain was taken as the colicine titre and was about 10^4 for both $P+$ and $P-$ culture fluids. Removal of pili and spheroidal surface material by centrifugation left the colicine activity in the supernatant fluid.

Thus, the above experiments are consistent with the view that pili are the organs of hæmagglutination, spheroidal surface material is the antiviral agent, and colicine *E* is associated with neither.

A possible correlation of piliation with fertility was investigated, but both $F+$ and $F-$ bacteria of one strain (*E. coli K*-12, *W*677) were piliated while neither $F+$ nor $F-$ bacteria of another strain (*E. coli K*-12, 58–161) were piliated. A strain of *E. coli* showing high frequency of recombination (*Hfr* of Hayes[17]) was non-piliated.

No non-flagellated strain of *E. coli* was ever motile although many were piliated. Piliation seems to occur quite independently of flagellation and motility. The pili of motile strains are usually much shorter than in non-motile strains, presumably due to fracture of the pili by bacterial motion.

Chemistry

Preliminary chemical analysis of partially purified pili suspensions indicate that pili contain at least some protein. Kjeldahl analysis showed 4·6 per cent nitrogen; xanthoproteic and biuret tests were strongly positive; the ninhydrin test was slightly positive before and strongly positive after prolonged acid hydrolysis. The ultra-violet absorption spectrum has a maximum at 279 mμ and a minimum at 252 mμ, which is typical for many proteins. Pili are precipitable by ammonium sulphate or acid.

Pili seem to be quite stable. Morphologically, the pili of *E. coli B L(E)P* are unaffected by long standing at pH 3–12 at room temperature or by heating to 95° for 2 min. at pH 7 or 10. This is in agreement with the observations of Weibull[9] for *Proteus* pili and of Duguid *et al.*[5] for pili of *Shigella flexneri*. Weibull found that pili of *Proteus vulgaris* were resistant to 1 *N* hydrochloric acid or sodium hydroxide, trypsin, pepsin, ribonuclease, or deoxyribonuclease as judged by appearance in the microscope. He also found that flagella from the same strain disintegrated at a low pH while the pili did not. In the light of the resistance of pili to various protein denaturants it seems unlikely that they are pure proteins.

Serology

A pure rabbit antiserum against *E. coli B L*(*E*) pili was prepared by several courses of injection of an electrophoretically separated pili suspension. This antiserum agglutinated a pure $P+$ culture after 1 hr. at room temperature at a dilution of 2,560 but did not agglutinate a pure $P-$ culture even at a dilution of 2. This serum has not yet been tested for cross reactions.

The growth of $P+$ and $P-$ colonies on agar plates is completely unaffected by the presence of anti-pili serum at an agglutination titre of 500.

I wish to thank Dr. Edouard Kellenberger and Dr. Max A. Lauffer for constant advice and encouragement, and Mrs. Alice McGough for her competent technical assistance. This research has been supported in Geneva by the Fond Nationale Suisse.

THE REFINING OF URANIUM IN THE UNITED KINGDOM

By D. P. HAMILTON

Chemist Training Officer, Springfields Works, U.K. Atomic Energy Authority

IN the Atomic Energy Act of 1946, the Prime Minister (then Mr. C. Attlee) announced the setting up of an organization within the Ministry of Supply to produce fissile material. Ten years later, as a result of the efforts of everyone in this completely new industry, which embraces every branch of science and engineering, Calder Hall, the world's first nuclear power station, began generating electricity for the national grid. The growth of the organization during the years between had been so rapid that in 1954, a separate body, the United Kingdom Atomic Energy Authority, was formed, a step made necessary because flexibility and speed of decision were required, and these would be obtained more easily from an organization set up on industrial rather than Civil Service lines. In addition, the creation of the Authority facilitated co-operation with all branches of industry, and as a result, the functions of the Authority—"to cover the whole field of Atomic Energy and radioactive substances"—could be rapidly and most economically developed.

The success of the British atomic energy project depends entirely on the production of uranium in a highly refined state, and the Springfields Works of the Authority is thus in a position of prime importance in supplying the country's requirements of natural uranium fuel elements for reactors such as those used at Calder Hall, Chapel Cross, and those shortly to be commissioned by the electricity generating boards, besides the fuel required for experimental nuclear reactors. During the past ten years, Springfields Works has produced almost one million fuel elements of varying kinds, and now, to meet the demands of the national nuclear power station programme—which envisages an installed generating capacity of 5–6 thousand megawatts by 1966 from nuclear power stations, a new Springfields Works has been built to supply the fuel elements required by those stations. Those new Works were open recently to the Press and, as a result, it is now possible to describe briefly the work which goes on there.

Uranium ore arrives at the factory in sealed drums from various Commonwealth countries, in the form of uranium concentrates which have been prepared from low-grade uranium-bearing ores from Canada, South Africa and Australia, by leaching with sulphuric acid in the presence of an oxidizing agent (such as manganese dioxide or sodium chlorate) at the mining site, producing a material which contains 70–90 per cent uranium oxide.

The ore concentrate on arrival at Springfields is tested for its uranium content before being tipped into large stainless steel dissolvers, where it undergoes a 'stewing process' with nitric acid to dissolve out the uranium (and other metallic elements) as uranyl nitrate. This part of the process may be represented by the reaction:

$$\underset{\substack{\text{uranium}\\ \textit{ex.}\text{ ore}}}{U} + \underset{\substack{\text{nitric}\\ \text{acid}}}{4HNO_3} \rightarrow \underset{\substack{\text{uranyl}\\ \text{nitrate}}}{UO_2(NO_3)_2} + \underset{\substack{\text{nitric}\\ \text{oxide}}}{2NO} + \underset{\text{steam}}{2H_2O}$$

The uranyl nitrate along with undissolved material is fed to the trough of a rotary filter. As the solution of uranyl nitrate is sucked through the specially prepared filtering surface of the horizontally rotating drum and discharged from the centre of the drum, the insoluble impurities collect on the surface and are removed by an advancing knife-edge.

The filtered uranyl nitrate solution is freed from other dissolved matter by a solvent extraction process. Uranium has the property of selective solution in certain oxygenated organic solvents; with tributyl phosphate the uranyl nitrate forms a complex, $UO_2(NO_3)_2.2(C_4H_9)_3PO_4$, which is soluble in odourless kerosene, the latter being used in admixture with the tributyl phosphate as a diluent. The kerosene–uranyl nitrate–tributyl phosphate complex solution is mixed with a dilute nitric acid solution to remove the impurities and the mixed phases of different specific gravities are then allowed to settle out into two layers. This 'mixing–settling' process continues in a specially designed counter-current extractor so that removal of the uranyl nitrate from the aqueous phase and its transfer to the solvent phase may be made almost complete. From this extractor the solvent mixture emerges loaded with uranyl nitrate, and then enters a similar type of extractor to meet a backwash of demineralized water. The result is a flow of pure uranyl nitrate in aqueous solution.

The purified uranium is precipitated from the aqueous solution as ammonium diuranate by the addition of ammonium hydroxide :

$$\underset{\text{uranyl nitrate}}{2UO_2(NO_3)_2} + \underset{\text{ammonium hydroxide}}{6NH_4OH} \rightarrow \underset{\text{ammonium diuranate}}{(NH_4)_2U_2O_7} + \underset{\text{ammonium nitrate}}{4NH_4NO_3} + \underset{\text{water}}{3H_2O}$$

The diuranate is then passed in batches through the 'dryway process', where it is converted to uranium tetrafluoride in a reacting vessel placed in an electrically heated furnace. The atmosphere inside the vessel is changed at each of three stages of the process. In the first stage the diuranate is calcined to drive off ammonia and steam, thus converting it to uranium trioxide :

$$\underset{\text{ammonium diuranate}}{(NH_4)_2U_2O_7} \rightarrow \underset{\text{uranium trioxide}}{2UO_3} + \underset{\text{ammonia}}{2NH_3} + \underset{\text{steam}}{H_2O}$$

During the second stage, hydrogen is admitted to the reacting vessel to reduce the trioxide to the dioxide :

$$UO_3 + H_2 \rightarrow \underset{\text{uranium dioxide}}{UO_2} + H_2O$$

The third, and final, stage converts the dioxide to uranium tetrafluoride by means of hydrogen fluoride gas :

$$UO_2 + \underset{\text{hydrogen fluoride}}{4HF} \rightarrow \underset{\text{uranium tetrafluoride}}{UF_4} + 2H_2O$$

This conversion process from uranyl nitrate to uranium tetrafluoride is also to be modernized and made continuous instead of batchwise by the introduction of fluidized bed techniques, and the plant for this is at present under construction. When it is complete, the uranyl nitrate solution will be concentrated and then sprayed into the first of three linked reactors. The water will be removed and the nitrate decomposed to form uranium trioxide powder, which will be fluidized by an upward current of air and transferred to the second reactor. Here the fluidizing gas will be hydrogen, which will reduce the uranium trioxide to dioxide, and finally in the third reactor a stream of anhydrous hydrofluoric acid will complete the conversion to uranium tetrafluoride.

It is from this tetrafluoride that the thermal metallic reduction occurs to give pure uranium metal. The choice of a reducing metal is limited to calcium or magnesium, and at Springfields magnesium is used because it can be obtained in very pure form and also at a lower price than calcium, although there is the disadvantage that with magnesium the reaction must be carried out in a sealed reacting vessel, externally heated.

The tetrafluoride is intimately mixed with magnesium turnings and fed into a pelleting press which ejects pellets of the mixture for delivery to the reaction vessel. This is a long steel cylinder lined with graphite sleeves inside which the pellets are built up. The loaded reaction vessel is then placed in an electric furnace, where the reduction reaction occurs :

$$UF_4 + 2\,Mg \rightarrow U + \underset{\substack{\text{magnesium fluoride}\\ \text{(slag)}}}{2\,MgF_2}$$

Although a temperature of several hundred degrees is required to initiate the reaction, it is strongly exothermic and produces a high enough temperature in the crucible for the uranium to be formed in a molten state. Its high density causes it to collect as a solid billet in the base of the vessel, with a slag of magnesium fluoride above it.

On cooling, the vessel is dismantled and the slag and uranium billet removed. The latter is cleaned of adhering slag, sampled for chemical purity, and then passes from the purely chemical process to the metallurgical side of the process—the conversion of the pure uranium metal into a fuel element.

The uranium billet is melted in a graphite crucible in an induction vacuum furnace from which the molten metal drops into a number of vertically arranged cylindrical moulds via a distributor plate. After cooling, the mould assembly is dismantled and the rods removed, each casting being kept separate. In order to bring the rods into a satisfactory metallurgical condition, that is, to minimize distortion or 'creep' during irradiation in the pile, they now undergo two heat-treatment processes—quenching and annealing, the object of which is first to reduce the grain size of the uranium crystals and give them a random orientation, and then to release any stresses set up in the metal as a result of this operation. On completion of the heat treatment processes, the metal rods are machined on conventional types of lathes, checked for dimensional accuracy and rigorously inspected before being passed on for assembly into fuel elements.

It is necessary to seal the uranium rod in a suitable container to prevent escape of gaseous fission products into the pile coolant, to prevent possible reaction of the coolant with the uranium rod, and to restrict the deformation of the rod resulting from irradiation and repeated heating and cooling.

The cans used at Springfields consist of helically finned open-end tubes made from magnesium alloy known as 'Magnox'. These cans are made scrupulously clean by immersion in trichlorethylene, after which they undergo a comprehensive examination for possible errors in fabrication. Following this, one end is sealed by an argon-arc welding technique and the uranium rod is inserted into the can. The second end cap is then welded into position and the completed fuel element undergoes pressurizing in an autoclave to squeeze the can on to the rod to ensure good heat transfer from rod to can. The fuel element is then examined by X-rays in order to detect any flaws which may have arisen during the canning process, cleaned once more, a brace assembly fitted, end pieces attached, and finally inspected before dispatch for use in the nuclear reactor.

In the short space of ten years, Springfields Works has built up an unrivalled team of personnel skilled in the techniques of refining uranium and fabricating fuel elements, and they are confident that the United Kingdom nuclear power programme, and the performance of British reactors abroad, rests on the firm foundation of a reliable fuel.

OBITUARIES

Prof. F. J. Cole, F.R.S.

FRANCIS JOSEPH COLE was born at Clapham in 1872, and by his death on January 27, a week before his eighty-seventh birthday, British zoology lost an outstanding scholar. He was educated at Sir Walter St. Johns School, Battersea, where the only science subject he studied was physics. Reading Darwin's "Vegetable Moulds and Earthworms" in his teens inspired him to keep and study these creatures, and his first three publications were notes on his observations. He also started buying books, and E. B. Wilson's classical memoir on the development of the earthworm made a deep impression on him by the accuracy of description, careful illustration and extensive bibliography.

In 1892 he was assistant to Prof. J. Cossar Ewart in Edinburgh, and his experience while there played a significant part in shaping his subsequent career. He collaborated with Ewart in a paper on the cranial nerves of elasmobranchs, the forerunner of a series of publications on the cranial nerves of fishes which firmly established his reputation as an able comparative anatomist and were recognized by the award of the Rolleston Prize by Oxford in 1902. These researches contributed to the establishment of the now generally accepted 'component theory of the nervous system' and they brought to his notice the works of the old masters of anatomy.

In 1895 Cole went to Liverpool as lecturer under Prof. W. Herdman, continued his line of research, and with James Johnstone produced "*Pleuronectes*", which still remains the longest of the well-known Liverpool Marine Biological Committee (L.M.B.C.) memoirs and shows clearly his noteworthy dexterity in dissecting and illustrating. A proposed memoir on the sea lamprey, *Myxine*, became expanded into a detailed monograph and brought him into contact with Prof. G. B. Howes, whom he regarded as the most learned zoologist he had ever met and the main person to substantiate his interest in bibliography. The first part appeared in the *Transactions of the Royal Society of Edinburgh* in 1905 and was followed by five further parts which set a standard of meticulous accuracy that has not often been reached. As the result of the earlier parts of this and his other work, he received the Neill Gold Medal of the Society. While at Liverpool, arrangements were made for him to keep terms at Jesus College, Oxford, where he obtained his B.Sc., and later the University conferred on him the D.Sc.

Cole went to what was then University College, Reading, in 1905 to found a Department of Zoology, and the following year was appointed to the chair, which he held until his retirement in 1939. He threw himself whole-heartedly into the task of building up the Department and, indeed, by his example and wise counsel played an appreciable part in the development of the young University. One of his first objects was to set up a museum, which from the beginning contained deliberately chosen specimens most carefully prepared and mounted and catalogued and written up in several volumes. It formed an outstanding and widely admired feature of the Department and represented an enormous amount of hard work and thoughtful planning. He retained a connexion with Liverpool, for he continued to take his senior students to Port Erin Biological Station, and several of his students contributed important memoirs to the Liverpool Marine Biological Committee series. In 1926 he was elected a Fellow of the Royal Society.

His inquiring mind and interest in things historical turned Cole's attention to the medieval architecture of the churches in the countryside around Reading and to the writing of an interesting analysis of the church of St. Mary, Cholsey. He now devoted more attention to the bibliography and history of comparative anatomy and published a number of contributions on these subjects, including, in 1944, an important book on the "History of Comparative Anatomy: from Aristotle to the Eighteenth Century". Always interested in books, he gathered a most remarkable and valuable library in his own field, which contains a number of very rare early works and is exceptionally complete. Indeed, the museum of his Department and his library were his much-loved and cared-for 'scientific children'. His first contribution to *Nature* was in 1895, and then there was a long gap; but readers will recall the series of articles and reviews since his retirement that gave some indication of his wide knowledge and sound judgment. His particular period was the Dutch microscopists of the seventeenth century, especially Leeuwenhoek. Just before and during this time he played a much appreciated part in the development of the newly instituted subject of history and philosophy of science in the University of London. For twenty-five years he served as external examiner and for a year less as member of the Board of Studies.

He was a tall, impressive man who would have appeared somewhat forbidding if this were not contradicted by the twinkle in his eyes. Gifted with a most retentive memory and, in addition to his zoological and bibliographical lore, a good knowledge of classical music and of the old masters of the Dutch and Flemish Schools, his conversation was well worth while, particularly as it was spiced with a quiet, dry humour. His teaching was always thorough and inspiring, and his students retained a great respect and affection for him. He will retain a warm place in their memories and in those of his colleagues. He is survived by a wife and a son, to whom we offer our sincere sympathy. CHAS. H. O'DONOGHUE

Dr. Karl Jordan, F.R.S.

IT is not given to many men to cover a span of seventy years with worth-while contributions to any science. Karl Jordan's first published work was an account of the lepidopterous fauna of Göttingen, a university dissertation submitted on his doctorate. In the next three years he gave rein to his childhood passion for beetles by publishing numerous supplements to the list of beetles of Hildesheim, his home town, near which he was born on December 7, 1861. The seventh son of a small farmer, Heinrich Ernst Karl Jordan had many duties to perform, besides going to school; but it was while going about these tasks that he had become interested in insects. He often related that the Carabidae in particular fascinated him. It was not just because they varied so much in colour, nor was it the mechanism of this variation that attracted him; the great question was 'why' did they vary. It is this theme that runs like a thread through all his writings.

At Göttingen he had been awarded the coveted *Summa cum Laude* in botany and zoology and afterwards obtained a diploma in teaching—a fact which his own daughters learnt later to appreciate. A year of voluntary military training was followed by appointments in the grammar school at Münden and at the School of Agriculture at Hildesheim. In 1891 he was able at last to marry the girl who had waited for him since both were in their 'teens; their marriage could not have been happier.

At the age of thirty-two, already with wide experience behind him, Jordan seemed set for a distinguished academic career. It was then that chance brought him in contact with Ernst Hartert, who had just been appointed by Walter (later Lord) Rothschild to be director of the Zoological Museum which he had formed at Tring—in two small cottages. Jordan's first task on arrival at Tring was to reduce to order the immense but chaotic collection of beetles (the Lepidoptera were already in better shape) stored in various parts of Tring, without proper working conditions or even a microscope. It was just what he wanted, a marvellous enforced exercise in the study of geographical variation, and any odd corner served as a bench. However, it soon became apparent that not even his devoted labours, carried far into the night, could cope with both the Coleoptera and the Lepidoptera at Tring, and before long the collection of the former was abandoned, except the Anthribiidae, a group of weevil-like beetles the complexity of which never ceased to fascinate Jordan, and on which alone he published more than eighty papers.

Meanwhile, Walter Rothschild, who was deeply involved in a systematic revision of the swallow-tail butterflies of the Oriental Region, enlisted Jordan's help. In a long introductory passage, Jordan (1895) proved himself some fifty years ahead of his time: he clearly appreciated the importance of populations as basic taxons, distinguished between individual, environmental and geographical variation, according the last firmly and precisely subspecific rank and applying a trinomial system of nomenclature exclusively to it. Here, too, he recognized the importance of the type system. During the next ten or twelve years other similar monographs appeared, on the hawk-moths, on the American swallow-tails, on the genus *Charaxes*, on certain families of emperor moths. These impressive monographs were built soundly on the most painstaking attention to detail, whether concerned with morphological minutiæ, distribution or bibliography; all the essential evidence available at the time, and a very great deal of entirely new and original matter, were welded together concisely in masterly fashion. However, this systematic work was by no means an end in itself.

Simultaneously, Jordan was publishing on pure morphology, on sense organs, on mimicry among butterflies and its significance for evolution, on geographical variation in relation to evolution, on 'mechanical' selection, and so on. Throughout his writings there is the constant theme that experimental biology and systematics are interdependent; neither can be complete, or even wholly dependable, without the other. The study of systematics was to him a means for proving the truth of evolution, and, as another writer has said, he "exerted an influence on the development of systematics and on evolutionary thought that cannot be over-estimated". It is quite possible, however, that his unpublished influence was equally great, for no one could have been more generous than Jordan in the inspiring help he gave so freely to his innumerable correspondents in all parts of the world.

At the age of seventy-four, Jordan made his first really ambitious collecting expedition, to South West Africa. When well over eighty, he remarked that it was time he started on his catalogue of fleas, a task he felt he owed to Charles Rothschild. The story of their fruitful co-operation has been told elsewhere; it was left to Miriam Rothschild, one of his most ardent disciples and admirers, to undertake this task, with the help of the Trustees of the British Museum. On his ninety-fourth birthday the Royal Entomological Society of London published a special volume in his honour, an event unique in its history and more significant an indication of the esteem in which he was held than anything these few words can convey. My own lasting impression is one of effervescent enthusiasm, intense interest in discovery and in the future, of the unexpected wit with which he would enliven a dull discussion, of his unfailing, unstinted help and kindliness, and of the fruitfulness of his long and happy life. He died on January 12, in his ninety-eighth year. N. D. RILEY

Dr. J. Travis Jenkins, O.B.E.

DR. JAMES TRAVIS JENKINS died on January 12, at his home, Henbant Hall, Capel Dewi, Llandyssul, Cardiganshire. Born in 1876, the son of a schoolmaster, he attended school first at Pontardawe, Glamorgan, and then at the Merchant Venturers' School, Bristol. Afterwards he attended the University Colleges of Aberystwyth and Cardiff, and in 1897 graduated B.Sc. of the University of Wales. Only three years afterwards (1900) he was awarded the doctor of science degree of the University of Wales for a thesis on the anatomy of the oyster. His early preoccupation with marine zoology, and particularly with its economic aspects, was also shown in his work at Kiel, where a year or two later he was awarded a doctorate of philosophy.

In 1904 Jenkins was appointed superintendent of the Lancashire and Western Sea Fisheries Joint Committee, and this post he held until his retirement in 1946, except for a short period during 1908–10, when he was seconded to the Bengal Government to investigate and organize the fisheries of the Bay of Bengal. On Indian fishes and fisheries he published a number of papers, some under the seal of the Bengal Government, others in the *Records of the Indian Museum*. He retained his interest in the subject in later years, and even so late as 1938 an article by him on "The Fisheries of Bengal—Can they be Developed and Improved?" appeared in *Current Science*.

As superintendent of the Lancashire and Western Sea Fisheries Joint Committee, Jenkins was responsible for a long series of quarterly reports dealing with the mussel, cockle and other fisheries of the Committee's district and with the various laws and regulations relating to these. In addition to his scientific qualifications, he was admitted a barrister of Gray's Inn in 1910. He acted for many years as honorary secretary of the Association of Sea Fisheries Committees of England and Wales. His work for the inshore fisheries was recognized by his appointment as O.B.E. in 1941.

He will be chiefly remembered for a series of books relating to fisheries and fishes: "The Sea Fisheries" (1920); "A Textbook of Oceanography" (1921); "A History of the Whale Fisheries" (1921); "The Herring and the Herring Fisheries" (1927); "Whales and Modern Whaling" (1932); and, best known of all, "The Fishes of the British Isles", the first edition of which appeared in 1925 and the second in 1936. He had always a keen interest in the historical and literary aspects of the fishing industries, and his last publication, issued in 1948 by the Society for the Bibliography of Natural History, was a comprehensive "Bibliography of the Whale Fisheries".

Jenkins was for many years a member of the Council of the National Museum of Wales. I recall with appreciation not only his many donations of specimens to the Zoology Department of the Museum but also his companionship both abroad and on collecting trips on board the Lancashire and Western Committee's steamer, the S.S. *James Fletcher*.

COLIN MATHESON

Mrs. E. W. Sexton

THE death occurred on February 18, at the home of her son at Alfriston in Sussex, of Mrs. Alice Wilkins Sexton, at the age of ninety. Although without scientific academic training, Mrs. Sexton (known under her adopted initials of 'E. W.') became an authority of international repute on Crustacea. Living at Plymouth, where her husband was a dentist, she began to work at the Laboratory of the Marine Biological Association at the beginning of this century under the guidance of the late Dr. E. J. Allen, for whom she made beautiful drawings of polychætes. Later, she was appointed a member of the scientific staff of the Plymouth Laboratory.

She was most noted for her systematic work on amphipods, and for the detailed study she made of the growth, moulting, intersexes and genetics of *Gammarus*. In the latter she concentrated especially on eye colour. The names of her species, *Gammarus chevreuxi* and *G. zaddachi*, are well known to biologists. All her publications were accompanied by examples of her meticulously careful and accurate drawings, which were at times astonishing in their detail.

A woman of remarkable vitality, she had many interests, notably the cultivation of unusual plants from many countries. Until she had to leave Plymouth in 1957 owing to failing eyesight her hospitable home, with its many and varied treasures, had been open to a very wide circle of friends from Britain and elsewhere.

Mrs. Sexton was a Fellow of the Linnean Society. She leaves a married son, Col. F. B. W. Sexton; her daughter Mary, who was librarian at the Plymouth Laboratory, died in 1951.

F. S. RUSSELL

NEWS and VIEWS

Pharmacology at Oxford: Prof. J. H. Burn, F.R.S.

JOSHUA HAROLD BURN has been professor of pharmacology in Oxford since 1937. His restless energy has built the most active pharmacological department in the world. Many of his students have learned to do accurate experiments and to write clear papers. He has attracted workers from many countries, who came to learn the techniques of which he is master. He is retiring at the age of sixty-seven, but shows no sign that his mind is less active than it was. He was educated at Barnard Castle School, University of Cambridge, and Guy's Hospital, London. Like many others, he derived inspiration from H. H. Dale, with whom he worked before the First World War at the Wellcome Physiological Research Laboratories, and then, after service in the Royal Engineers, in the National Institute for Medical Research. In 1926 he became professor of pharmacology in the College of the Pharmaceutical Society and director of a laboratory which undertook the biological standardization of drugs on a large scale. He wrote a book which laid the foundations of accurate methods of assay, and he has written at least half a dozen other books on various aspects of pharmacology, and large numbers of scientific papers, lectures, reviews, editorials and reports of various kinds. He makes up his mind and puts his thoughts on paper without trouble or delay, and has provided a very potent stimulus to the development of pharmacology. His work has been concerned with all classes of drug, but has been especially important when he has used pharmacological methods to solve physiological problems.

Prof. W. D. M. Paton, F.R.S.

WILLIAM DRUMMOND MACDONALD PATON succeeds Burn as professor of pharmacology at Oxford. He was born in 1917 and educated at Repton School, the University of Oxford, and University College Hospital, London. He joined the staff of the National Institute for Medical Research in 1944. During his eight years there he made his name by two outstanding pieces of work. With F. C. MacIntosh he showed that various simple organic bases cause the release of histamine, which disappears from the tissues of animals. It has thus been possible to study not only the mechanisms of release, but also the effects of removing most of the histamine, which are surprisingly small. With E. Zaimis he discovered not only that small doses of decamethonium cause neuromuscular blockade by depolarizing the end plate, but also that hexamethonium blocks transmission through autonomic ganglia. The analysis of the mode of action of these drugs by these two workers became a model for such studies. Hexamethonium was the first drug shown to have a really powerful and specific action on peripheral autonomic ganglia. It has been invaluable as a research tool, but it is best known as the basis of the first really effective treatment for high blood pressure. This was a major advance in therapeutics and led to the award of the Cameron Prize to Paton and Zaimis in 1956. In 1952 Paton went as reader to University College and in 1954 he was appointed to the newly founded chair of pharmacology at the Royal College of Surgeons.

Organic Chemistry at Birmingham : Prof. J. C. Tatlow

As part of the large expansion programme of the Department of Chemistry at the University of Birmingham, a new chair of organic chemistry has been created. Dr. J. C. Tatlow, at present reader in organic chemistry in the Department, has been appointed to be the first holder of the chair. Dr. Tatlow entered the University of Birmingham in 1940 to read chemistry with county major, State and Rugeley Grammar School scholarships. He was Burstall Prize-man in 1941 and Frankland Prize-man in 1943, when he gained his B.Sc. with first-class honours. He obtained the Brotherton Research Scholarship and was appointed to the staff of the Department of Chemistry in 1944 as leader of a research group engaged on fluorine and uranium chemistry. In 1946, after gaining his Ph.D., he was appointed scientific officer in the Ministry of Supply at the Chalk River Atomic Energy Establishment in Ontario. He returned to Birmingham in 1948, first as an Imperial Chemical Industries Fellow and later as lecturer in chemistry. Since that time he has led a large team engaged in the chemistry of organic compounds and is joint or senior author of some seventy original papers in that field. He was awarded his D.Sc. in 1954 and his Fellowship of the Royal Institute of Chemistry in 1955. He has for many years been a member of the Midlands Section of the Royal Institute and a local representative of the Chemical Society. He was appointed a member of the Council of the Chemical Society in 1957. He is playing a prominent part in organizing the First International Congress on Fluorine Chemistry to be held in Birmingham in July next. He was appointed senior lecturer in chemistry at Birmingham in 1956 and reader in organic chemistry in 1957. He has had wide teaching and organizing experience and is a member of the Pure Science Board of Examiners. He has played a major part with Prof. M. Stacey and Prof. J. C. Robb in the design and planning of the new chemistry buildings at Birmingham.

Engineering Production at Birmingham : Prof. N. A. Dudley

Dr. N. A. Dudley, recently reader in engineering production and head of the Department of Engineering Production in the University of Birmingham, has been appointed to the chair in that subject at Birmingham. Dr. Dudley was born in 1916 and educated at King's Norton Grammar School and Birmingham Central Technical College. Before his appointment in 1945 as lecturer in production engineering and management at Burton-on-Trent Technical College, he was a production engineer in industry. In 1947, he became a member of the staff of Birmingham Central Technical College, and during 1948–52 he was senior lecturer in the Department of Engineering Production at Wolverhampton and Staffordshire Technical College. He was then appointed lecturer in engineering production in the University of Birmingham and in 1956 was made reader and head of the Department of Engineering Production and also head of the Institute for Engineering Production.

Nuclear Science and Technology at the Royal Naval College, Greenwich : Prof. J. Edwards

Mr. J. Edwards, senior principal scientific officer and head of the Naval Section at the Atomic Energy Research Establishment, Harwell, has been seconded from the Royal Naval Scientific Service, and appointed to the new chair of nuclear science and technology, recently established at the Royal Naval College, Greenwich. During his four years at Harwell, Mr. Edwards was responsible for the extensive programme of experimental work which has been carried out by the Atomic Energy Research Establishment and the naval scientists there and he has, therefore, a wide experience of reactor systems cooled and moderated with ordinary water, and the general problems involved in the small reactor plants likely to be suitable for mobile purposes. He has twice visited the United States in connexion with these developments and last year delivered a lecture on the prospect of nuclear propulsion to the Engineering Section of the British Association in Glasgow. He was also one of the Admiralty delegates to the recent Geneva Conference on the Peaceful Applications of Nuclear Energy. Prof. Edwards served his engineering apprenticeship in Chatham Dockyard and obtained a Whitworth Scholarship to the City and Guilds College of the University of London, where he took an honours degree in engineering. He has since served in a variety of Admiralty research establishments including the Torpedo Experimental Establishment, the Admiralty Engineering Laboratory, where he was concerned with detailed stress and vibration investigations and gas turbine analyses, and the Department of Engineering and Materials Research in charge of studies and experimental work on advanced propulsion systems. In 1953 he was appointed to the staff of the Commander-in-Chief, Home Fleet, as scientific advisor concerned with operational research problems, serving in this capacity for some fifteen months in both H.M.S. *Vanguard* and H.M.S. *Tyne*. He has also been concerned with tripartite negotiations leading to standardization in the shock and vibration field.

Research Laboratory, British Museum : Dr. H. J. Plenderleith, C.B.E.

Dr. H. J. Plenderleith has retired from the keepership of the Research Laboratory of the British Museum, Bloomsbury, to become the first director of the International Centre for the Study of the Conservation and Restoration of Cultural Property, in Rome. After distinguished service in the First World War, he joined the British Museum Laboratory under the late Dr. Alexander Scott, succeeding him in course of time as head of the Department. The Laboratory now has an international reputation, and its advice is sought over an extremely wide range of objects and their care. When the Honorary Scientific Advisory Committee of the National Gallery was formed in 1935, Dr. Plenderleith was one of its original members and was chairman during 1944–58. In 1936 he succeeded the late Prof. A. P. Laurie at the Royal Academy, retiring from the chair of chemistry there last year. During 1950–58 he served the International Institute for the Conservation of Museum Objects as its first honorary treasurer, and is now a vice-president. The author of numerous publications and lectures, Dr. Plenderleith has collected the results of more than thirty years work in his book, "The Conservation of Antiquities and Works of Art", published in 1956. There are few countries which Dr. Plenderleith has not visited, and he was a member of the van Meegeren Commission in 1947. He is now chairman of the Museums

Laboratories Committee of the International Council of Museums, which meets in Copenhagen this coming summer. In 1934 he was elected a Fellow of the Royal Society of Edinburgh, and in 1956 he received the honorary degree of LL.D. from his old University, St. Andrews. He brings high distinction, both scientific and administrative, to his new office.

Dr. A. E. A. Werner

Dr. A. E. A. Werner, who succeeds Dr. H. J. Plenderleith as keeper of the Research Laboratory of the British Museum, Bloomsbury, was born in Dublin in 1911. He was educated at Trinity College, Dublin, and at the University of Freiburg-im-Breisgau, where he was awarded the degree of D.Phil. In 1937 he was appointed lecturer in organic chemistry in the University of Dublin, and in 1948 went to London as the first holder of the post of research chemist (senior scientific officer) in the Scientific Department of the National Gallery. In 1954 he transferred to the British Museum, as principal scientific officer. Dr. Werner has made a special study of the application of new synthetic materials to the conservation of works of art and is undertaking a detailed report upon adhesives to the Museums Laboratory Committee of the International Council of Museums, of which he is a member. For some years he has given valuable help to the Wall-Paintings Committee—a joint body set up by the Central Council for the Care of Churches, and the Society for the Protection of Ancient Buildings—to deal with the care of murals in Great Britain. In collaboration with J. S. Mills, he has made use of chromatographic techniques in the study of the natural resins. With his gift for languages and wide cultural interests, in addition to his scientific accomplishments, Dr. Werner is assured of the best wishes of a wide circle of friends and colleagues, both in Britain and abroad, as he enters upon his new responsibilities.

The Wykeham Chair of Logic at Oxford : Prof. H. H. Price

In October, Prof. H. H. Price will be succeeded in the Wykeham chair of logic at Oxford by Prof. A. J. Ayer, at present Grote professor of the philosophy of mind and logic, University College, London. Prof. Price, who was appointed to the chair in 1935 from a fellowship in philosophy at Trinity College, Oxford, began his philosophical career as an admirer of Prichard, Cook Wilson's most original and penetrating adherent. But in his first book, Perception" (1932), he expounded an essentially phenomenalist theory of perception, identifying material objects with families of sense-data, which was remote from Prichard's views. It was, in fact, a uniquely thorough and coherent articulation of the ideas about perception that had been put forward, in a comparatively tentative and unfinished way, by Russell and Moore in the preceding decades. It remains a standard work on the subject. In 1940 he published "Hume's Theory of the External World", not so much a commentary as a set of ingenious variations on the Humean theme that the conception of a material object is a construction out of sensory elements. Since 1945 Prof. Price's main publications have been in the domain of philosophical logic. "Thinking and Representation", his British Academy Lecture of 1946, foreshadowed the full-scale study, "Thinking and Experience" (1953), in which, among a great deal of careful and valuable analysis, the existence of imagery was resolutely defended against doubting linguistic philosophers, though their main point, that imagery could not be identified with the meaning of the words whose use it was associated with, was conceded. For many years Prof. Price has been actively interested in psychical research. He has considered the philosophical implications of its purported findings in a number of articles and has served as president of the Society for Psychical Research.

Prof. A. J. Ayer

Prof. Ayer's first book, "Language, Truth and Logic" (1936), which became well known outside the philosophical world for the vigour of its onslaught on metaphysics, traditional ethics and theology, was a presentation to the English-speaking public of the ideas of the Vienna Circle of logical positivists. It was also a more far-reaching piece of anglicization, since it applied techniques and principles worked out for the logical analysis of science to the analysis of knowledge in general. The thoroughgoing phenomenalism briefly sketched in it was more fully developed in "Foundations of Empirical Knowledge" (1940), which, its author states, owes more to Price's "Perception" than to any other work. Just as Prof. Ayer was prepared to go further than Prof. Price here by entirely rejecting material substance as something over and above actual and possible sensation, so, in "Thinking and Meaning", his inaugural lecture, delivered at University College, London, in 1947, he discarded the last relics of realism about universals which still figure in Prof. Price's examination of the same issue. In "Philosophical Essays" (1954) he collected a dozen substantial articles on philosophical logic, theory of knowledge and ethics. "The Problem of Knowledge" (1956), though designed as an introduction to philosophy, presents original contributions to the problems of perception, memory, the self and other minds.

Both Price and Ayer are masters of the lucid exposition of abstract subjects. Price's writing is notable for its charm and quiet humour, Ayer's for its brilliant concision and elegance. In Ayer's succession to Price the continuing strength and vitality of the British empirical tradition in philosophy is recognized.

Corday–Morgan Medal and Prize : Prof. G. W. Kenner

Prof. G. W. Kenner, Heath Harrison professor of organic chemistry in the University of Liverpool, has been awarded the Corday–Morgan Medal and Prize for 1957 for his contributions to synthetic organic chemistry, particularly in the field of peptide and nucleotide chemistry. This award, consisting of a silver medal and a monetary prize of 200 guineas, is made annually to a British chemist of less than thirty-six years of age, who, in the judgment of the Council of the Chemical Society, has published during the year the most meritorious contribution to experimental chemistry. Applications or recommendations in respect of the award for the year 1958 must be received not later than December 31, 1959, and applications for the award for 1959 are due before the end of 1960. Copies of the rules governing the award may be obtained from the General Secretary, Chemical Society, Burlington House, London, W.1.

Institute of Metals Medals

The Council of the Institute of Metals has made the following awards of medals: *The Institute of Metals (Platinum) Medal* to Dr. L. B. Pfeil (director, Mond Nickel Co., Ltd.) in recognition of his outstanding contributions to non-ferrous metallurgical science and to the non-ferrous metals industries; *The Rosenhain Medal* to Prof. R. W. K. Honeycombe (professor of physical metallurgy, University of Sheffield) in recognition of his outstanding contributions in the field of physical metallurgy; *The W. H. A. Robertson Medal and Premium* to Dr. R. B. Sims (chief engineer, Davy and United Engineering Co., Ltd.) for a paper on "Automatic Gauge Control in Rolling Mills", published in the *Journal of the Institute of Metals*, 86 (1957–58).

World Life Research Institute

Bruce W. Halstead, formerly of the School of Tropical and Preventive Medicine, College of Medical Evangelists, Loma Linda, California, has recently been appointed director of the World Life Research Institute now under construction in Reche Canyon, Colton, California. The new institute will be operated as a non-profit-making, scientific and educational organization with emphasis on fundamental research in the broad field of the chemistry of natural products; for example, phytochemistry and marine biotoxicology. The application of these compounds to medicine and industry is also of direct interest to the organization. Research will be conducted under contract and grants-in-aid from government and industry. A technical assistance programme will be developed, working in conjunction with certain under-developed countries, in the chemistry of natural products.

Colonial Development and Welfare

In moving the second reading of the Colonial Development and Welfare Bill in the House of Commons on March 2, the Secretary of State for the Colonies, Mr. A. Lennox-Boyd, said that the background to the Bill was explained in the report on the use of funds provided under the Colonial Development and Welfare Acts and outline of the proposal for exchequer loans to the Colonial territories issued as a White Paper (Cmnd. 672). The first part of the Bill extends the period of the existing Colonial Development and Welfare Acts and increases the money available for schemes made under the Act. All but 2 per cent of the money provided under the Acts had been in the form of grants, and expenditure was now running at over £12 million a year; from April 1946 to March 1958 it totalled £155,418,000. Of this, £13,255,000 was for research, for which commitments in the period totalled £17,203,000 or 8·9 per cent of the total, while a further 21·2 per cent was for communications, 14·2 per cent for agriculture, fisheries and forestry, 4·4 per cent for irrigation and soil conservation and 18·3 per cent for education. The latter figure included grants of £1,244,250 to the University College of Rhodesia and Nyasaland and £1,500,000 to the University of Malaya. Although some of the territories had now become self-governing Dominions, which under Clause 2 (7) of the Bill would cease to be eligible for Colonial Development and Welfare assistance, over the whole field more than four times as many administrative, technical and professional officers are being recruited than before the War. Mr. Lennox-Boyd referred particularly to the value of the work of the technical advisers to the Federal Government of the West Indies.

The Bill would provide £95 million of new money over the next five years, compared with £80 million made available in 1955 on the present quinquennium. Excluding the £24 million to be allocated to Malta but including the £44 million unexpended under the previous Acts, this would give £115 million for spending in the five years from April 1, 1959. In several territories the immediate effect of development has been to increase the demand on Government resources, and as external financial aid, mainly from the United Kingdom, is likely to be needed for many years the Bill introduced a novel plan of Exchequer loans. Provision was made for up to £100 million of such loans from the Government fund, over five years normally, to meet the cost of the loan-worthy element to general development programmes. The terms of these Exchequer loans will be fixed by the Secretary of State for the Colonies with the approval of the Treasury, but will not be more favourable than those on market issues. Mr. Lennox-Boyd said that the Bill was the next step in a programme of continuous assistance to Colonial governments and believed that it could facilitate a substantial expansion in development.

Funds for Commonwealth Students in Britain

In a statement circulated in *Hansard* for March 9, the Under-Secretary of State for Commonwealth Relations, Mr. C. J. M. Alport, said that of the £620,500 from United Kingdom Government funds available to Commonwealth and Colonial students in 1958–59 for study in the United Kingdom, £180,000 is under Colonial Development and Welfare, £315,000 under the Colombo Plan Technical Co-operation Scheme, £66,400 for British Council scholarships and bursaries, £4,500 under technical assistance to Ghana, £600 for the Federation of Malaya Merdeke Scholarship, £4,000 under Baghdad Pact technical assistance and £50,000 for Athlone fellowships. These funds are not necessarily restricted to university students but are available for further education or training at any suitable centre in Great Britain. In addition, a wide range of scholarships tenable in Britain is offered by the United Nations Special Agencies, charitable and educational trusts, universities, business firms and others.

Nato Studentships and Fellowships

In a written answer in the House of Commons on March 2, the Parliamentary Secretary to the Ministry of Works, Mr. H. Nicholls, representing the Lord President of the Council, said that the North Atlantic Council had decided to finance a science studentship and fellowship programme to start this year. The Department of Scientific and Industrial Research, in consultation with other interested Government bodies, would make these awards to British subjects normally resident in Britain. Under the programme the United Kingdom proposed to provide increased opportunity for study, research training and experience for postgraduate and postdoctoral students in science and technology (including medical and agricultural sciences, industrial psychology and sociology). The scheme was intended to stimulate international exchange of such students between North Atlantic Treaty Organization countries, but awards could be held in the home country of a student or in a country which was not a member of the Organization. The value of the awards and their conditions would be generally similar to those for studentships and fellowships of the Department of Scientific and Industrial Research.

Power Stations in Britain

In moving the second reading of the Electricity (Borrowing Powers) Bill in the House of Lords on March 3, the Minister of Power (Lord Mills) said that apart from the hydro-electric plant in the North of Scotland's programme, practically all the new generating plant, with a total capacity of 12·25 million kilowatts, which the Electricity Council intended to provide, would be coal-fired or nuclear, and it was estimated that nuclear power would absorb 47 per cent of the £1,100 million which the Central Electricity Generating Board proposed to spend on power-station construction. Of investment in power stations proposed over the next seven years, less than 4 per cent represented oil-fired plant, and within the past week, by agreement with the oil companies and the National Coal Board, conversion of two power stations from coal to oil would be postponed for a year. At present there were five consortia of firms with design teams trained by the Atomic Energy Authority and capable of tendering for the construction of complete nuclear power stations. As the number of nuclear power stations that will be built in Britain before 1966 will not now exceed twelve to fourteen, the opportunities for a new consortium will be somewhat limited in future, although there were opportunities here and overseas for the manufacture of small reactors, including research reactors. If a British firm could obtain permission to make use of, say, American development work so that it could sell in export markets reactors of a different type from those developed here, he saw no reason why it should not do so.

Dealing with distribution, on which expenditure totalling £700 million was proposed for the seven years, Lord Mills said that at present nearly 75 per cent of farms had a supply of electricity, and the programme as a whole was expected to be completed on time. The proposed storage scheme at Festiniog and one projected at Loch Awe would eventually provide 700 megawatts at peak hours. Other research on storage was proceeding and he was satisfied that this research programme was adequate.

University News:

London

Dr. A. R. Boothroyd, lecturer at the Imperial College of Science and Technology, has been appointed to the University readership in electronics tenable at that College; the title of reader in crystallography in the University has been conferred on Dr. C. H. Carlisle in respect of his post at Birkbeck College; Dr. R. F. Saxe, lecturer at Queen Mary College, has been appointed to the University readership in nuclear engineering tenable at that College.

Dr. B. J. Mason, Warren Research Fellow of the Royal Society at the Imperial College of Science and Technology, London, has been appointed visiting professor of meteorology by the University of California for the period June 1–December 31.

Sheffield

The University of Sheffield has received, among others, three grants from the Department of Scientific and Industrial Research: one of more than £15,000, spread over five years, to the Department of Fuel Technology and Chemical Engineering, for the study of the formation and combustion of coal smoke; a grant of £6,000 over three years in aid of its work to the School of Social Studies, to investigate the transition to work of boys and girls from secondary modern schools in the Sheffield area; a grant of £30,500 over five years to the Department of Electrical Engineering, for the study of almost fully ionized gases by millimetre wave-probe techniques, involving building a small thermonuclear reactor, like *Zeta*, in the Department.

Announcements

The Gold Medal of the Royal Aeronautical Society, the highest honour the Society can confer, for work of an outstanding nature in aeronautics, has been awarded to M. Marcel Dassault, the well-known French aircraft designer, for "his outstanding contributions to the design and development of aircraft". One of the first aircraft designed by M. Dassault was the *S.E.A.*4 in 1918, and the last aeroplane to be designed by him was the *Mirage IV*, a high-speed twin-engine bomber. Between the Wars he designed many successful French aircraft, including fighters, reconnaissance types, bombers and transports.

Prof. S. J. Angyal, head of the Department of Organic Chemistry, University of New South Wales, has been awarded the H. G. Smith Memorial Medal. The Medal is awarded every year by the Royal Australian Chemical Institute to the member who, in the opinion of the Council of the Institute, has contributed most to the development of some branch of chemical science.

The Operational Research Society has appointed Miss G. M. Heselton to be its secretary, and has moved into an office at 64 Cannon Street, E.C.4 (telephone, City 1800). The president is Prof. M. G. Kendall, of the London School of Economics, and the *Operational Research Quarterly* is published for the Society by Pergamon Press, Ltd.

Mr. Robert Douglas Baird has been appointed a director of Baird and Tatlock (London), Ltd., and of Hopkin and Williams, Ltd. Mr. Baird is a grandson of the founder of Baird and Tatlock (London), Ltd. He was educated at Winchester and Cambridge, where he read for the Mechanical Sciences Tripos. On leaving Cambridge, he joined the army in 1943; after demobilization in 1946 he returned to Cambridge to take the Certificate in Education, and since 1947 he has been teaching mathematics at Eton College, where he is also the careers master.

The Physical Society is holding a Conference on Nuclear Physics in the University of Oxford during April 8–10. The Acoustics Group of the Society is holding a Symposium on New Techniques in the Analysis of Noise and Vibration jointly with the Institute of Physics in the Physics Department, University of Southampton, on April 7. Further information can be obtained from Miss E. Miles, Physical Society, 1 Lowther Gardens, London, S.W.7.

A National Education and Careers Exhibition, organized by the National Union of Teachers, is to be held at Olympia during May 26–June 5. The Education Section will display all aspects of modern education from nursery school to university and adult education. The Careers Section will offer information and advice on careers in virtually all the main fields of employment. Inquiries should be directed to the National Education and Careers Exhibition Office, Hamilton House, Mabledon Place, London, W.C.1.

VEGETATION OF THE HUMID TROPICS

A SYMPOSIUM on "Humid Tropics Vegetation", sponsored jointly by Unesco and the Council for Sciences of Indonesia, was held during December 12–15 in the new Academy of the Ministry of Agriculture at Tjiawi near Bogor (formerly, Buitenzorg). Spacious accommodation delighted the delegates, mountain air fanned the discussions, and the wooded plain of Bogor made a fitting prospect. It was successor to the symposium on "Tropical Vegetation" held by Unesco in Kandy in March 1956. To judge from the strenuous programme, the full attendance, the vigorous exchange of views, and the unanimous decision to request a third symposium for 1960, the second was as successful as the first. Great credit for the organization must be given to Dr. Lennart Mattsson (director, Unesco South-East Asia Science Co-operation Office), Prof. Kusnoto Setyodiwiryo (director, Kebun Raya, Indonesia), Prof. Sadikin (director, Academy of Agriculture, Tjiawi), and Mr. Anwari Dilmy (director, Herbarium Bogoriense). Twenty-seven delegates attended from: Australia, Sarawak and Brunei, Cambodia, Ceylon, India, Pakistan, Singapore, Thailand, United Kingdom, United States, the Food and Agriculture Organization, and Indonesia.

Opening addresses on the first morning were given by Prof. Kusnoto Setyodiwiryo, Prof. Sarwono Prawirohardjo (president, Council for Sciences of Indonesia), Mr. Hutasoit (secretary general, Ministry of Education and Culture), and Dr. Mattsson. They set the tone of sincere appreciation of science which enabled the delegates, in the ensuing reception, to meet at once on common ground. In the afternoon and on the following days thirty-one papers were presented. These had been duplicated, bound, and distributed to delegates on arrival, so that the author was allowed some twenty minutes to review his theme and there was ample time for discussion. On the first afternoon, Prof. Kusnoto Setyodiwiryo introduced the subject of the "Flora Malesiana", as the backbone of botanical research in South-East Asia; it led to a number of resolutions concerning the progress of floristic botany in adjacent regions. Several reports were then given on ecological studies since the Kandy symposium.

The second day opened with Dr. F. R. Fosberg's (United States) presentation of a detailed classification of humid tropical vegetation based on plant characteristics without admixture of climatic and edaphic determinants. Such a purely botanical approach was welcomed, and his extensive and valiant key to vegetational categories will certainly be tested throughout the tropics. Prof. H. B. Gilliland (Singapore) described his method of evaluating and classifying secondary forests in Singapore. He championed a phase in ecology which foresters had neglected and bravely evoked the outspoken criticism which made this and succeeding discussions basic and fruitful. Dr. R. G. Robbins (Australia) gave a vivid account of vegetational mapping in eastern New Guinea by air survey and ground reconnaissance; probably no ecological work has been undertaken so rapidly and, as it appeared, so satisfactorily on so large a scale; it provided a reliable picture for land-utilization where no other survey was adequate. Mr. R. A. de Rosayro followed with a detailed account of aerial photography applied to forestry problems in Ceylon. Here, the smaller area permitted analysis with sample plots on the ground; it seemed clear that the virgin forest was in a state of dynamic equilibrium between associations dominated by *Mesua* or *Doona* and by mixed associations between them and *Shorea*. This novel theory provoked much comment; the greater variety of trees in Malaysian forests would obscure the effect. Dr. Y. Satyanarayan (India) described his method of evaluating dominance in Bombay forests by estimating crown-coverage. Dr. Robbins presented a paper by B. W. Taylor and R. O. Whyte (Food and Agriculture Organization) in which they developed the idea of a 'land-type' composed of 'land-units' as an exploitable entity; though intended for agrarian use, it became evident as discussion proceeded that such compound topographical concepts could well be applied to vegetation. Mr. Wyatt-Smith (Malaya) closed this part of the programme dealing with ecological methods by describing the Malayan forester's method of quantitative assessment of forest composition and structure. He emphasized the necessity for reconciling metric and British systems of enumeration with respect to quadrat-size and trunk-measure; a detailed resolution was afterwards taken up to this effect.

The third morning was given to papers on tropical peat-swamps, particularly of Borneo, as presented by J. H. R. Anderson, P. Shaw Ashton and A. J. G. H. Kostermans. To me this was the most interesting part of the programme for I had spent several years endeavouring to explore such forest in Malaya. To Unesco must go the credit for having first brought together experts on this peculiar, and intricate, vegetation so difficult of access. These papers and the ensuing discussion should be perused by all interested in tropical forests because the peat-swamps are an integral step in lowland forest succession; they are being exploited, and there is urgent need of study before axe and poison can destroy them for ever. Yet it was evident that here, as in many other cases, discrepancies arose not from errors in observation or from misunderstanding but from profound differences in the phytogeographical, geological and topographical nature of the regions considered, and that more intensive local study should precede generalization. In the afternoon, Mr. Kasin Suvatabandhu (Thailand) gave an account of Thailand forests, which are of great interest because of their marginal position both in the ecology and the floristics of the humid tropics; he pointed out that there was as yet no adequate definition of the humid tropics. Dr. Robbins concluded this session with a provocative new classification of mountain vegetation derived from his researches in the central highlands of eastern New Guinea. As this adds a new range to ecological knowledge of tropical mountains, his conclusions will be widely discussed. He proposed to get rid of the term 'mossy forest' and a resolution to this effect was approved; but reflexion leads me to conclude that this meaningful expression is still applicable where mountains do not partake in a 'central highland'.

The last morning continued with ecological problems. Dr. H. C. Trumble (Food and Agriculture Organization) described the climate of Indonesia in relation to vegetation and showed the necessity for many more meteorological records. His careful analysis should be read in conjunction with the 'land-systems' of Taylor and Whyte, for bioclimatology must complement their biotopography. Dr. Satyanarayan reviewed in detail the vegetation of the Western Ghats, where, as in Thailand, there is a transition from true humid tropical forest to the sub-arid. His account will be a standard reference for phytogeographers. Dr. Robbins then presented a paper by L. J. Webb on the rain-forest of Queensland; the importance of lianes was emphasized in the definition of forests, and the neglect of them shows how much is yet to be added to tropical ecology. Mr. Womersley gave an account of the work of the Botanical Division of Forestry in eastern New Guinea, and a second paper on the *Araucaria* forests in which he developed the theme that they were relics of ancient, even mesozoic, pre-angiosperm vegetation surviving fitfully in some unknown, possibly catastrophic, manner in the invading sea of broad-leafed forest. I think this paper will become a classic. Mr. P. R. Wycherley (Malaya) gave an elegant sketch of the ruderal behaviour of *Croton hirtus*, and a valuable analysis of an acre of forest in Malaya, such as will become a standard of reference for Malaysian ecologists. The afternoon was devoted to problems of sylviculture in Indonesia, presented by Mr. Mursaid, and in Malaya, presented by Mr. Wyatt-Smith. Striking differences were apparent, especially from the methods described for Ceylon by Mr. de Rosayro, and it was clear, again, that generalization could be misleading. In the evening Dr. Fosberg, as *rapporteur général*, gave an able summary of the proceedings, and closing speeches were made by Prof. Kusnoto Setyodiwiryo and Mr. Sudiman (secretary, Council for Sciences of Indonesia).

After the symposium delegates were taken under the leadership of Dr. A. J. G. H. Kostermans (Indonesia) to the mountain garden and nature-reserve of Tjibodas, to the Botanic Garden at Bogor, for a four-day excursion to the nature reserve of Udjong Kulon at the south-west corner of Java, and on a ten-day excursion to central and eastern Java and to Bali. Few delegates, unfortunately, had time for this trip, but that to Udjong Kulon in the research ship of the Kebun Raya gave them the unforgettable scene of Krakatoa, as the ship sailed about 8 a.m. between the new erupting cone and the old forest-clad mountain-side.

As one whose presence was fortunate rather than premeditated, I may make a few detached remarks. Such a small symposium of picked experts, discussing their problems in such hospitable, if remote, circumstances must always be rewarding. Its success depended in no small measure on the accomplishments of a few delegates, particularly Dr. Robbins and Mr. de Rosayro, who entertained us in the evening. At Tjiawi, we had an audience of students, and the proceedings, instead of being merely documented and shelved, may grow up in receptive minds. Malaya gave a good lead in sending both senior and junior delegates. We should remember these ingredients that the next may be as successful. E. J. H. CORNER

PRECIPITATION IN ALLOYS

FROM the early investigations of Wilm on the age-hardening of aluminium alloys, the study of the decomposition of supersaturated solid solutions has made rapid progress. For the past twenty years the subject has advanced largely through investigators using X-ray diffraction techniques, but within the past two years the pre-eminence of these techniques in this field has been challenged by investigators using the electron microscope to examine metals either directly by transmission or with the aid of extraction replicas. At a conference held at the Institution of Civil Engineers in London on November 28, and organized by the X-ray Diffraction and Electron Microscopy Groups of the Institute of Physics, an opportunity was given for the two groups of investigators to meet, outline their methods of approach and discuss the results obtained.

The conference comprised four principal papers—two devoted to results obtained by X-ray diffraction and two to results obtained by electron microscopy—followed by a general discussion. The first speaker was Prof. A. Guinier (Department of Physics, Conservatoire des Arts et Métiers, Paris), who described the structures of age-hardened alloys in the pre-precipitation stage. He first defined the Guinier–Preston zones in terms of the interface between the zones and surrounding matrix, pointing out the requirements for coherence. He then reviewed the evidence from which it has been possible to deduce the shape, size and structure of zones in various alloys based on aluminium and containing copper, silver, magnesium, silicon, germanium and zinc. In discussing the structure of zones in relation to the properties of alloys, Prof. Guinier pointed out that a change from a purely metallic to partially covalent or ionic bonding may occur as the zones increase in size and thickness.

The results obtained on the same series of alloys, but after examination by transmission electron microscopy, were described by Dr. J. Nutting (Department of Metallurgy, Cambridge). He showed how the predictions made from X-ray diffraction results have been confirmed by electron microscopy. He then went on to outline how the strain fields surrounding coherent precipitates may be observed and to discuss the transition from coherency to partial coherency at the precipitate–matrix interface. The advantages of the electron metallographic approach in revealing precipitate morphology were stressed and the importance of this morphology in relation to mechanical properties was briefly mentioned. The disadvantages of the electron metallographic approach is that it gives no clear indication of the zone and precipitate structure. The possibility of using selected area transmission electron diffraction was suggested as a means of overcoming this difficulty.

An account of her investigations on precipitation in aluminium alloys when using X-ray diffraction techniques was given by Miss J. M. Silcock (Fulmer Research Institute, Stoke Poges, and Department of

Metallurgy, Liverpool). She showed how the addition of small amounts of cadmium to an aluminium–copper–magnesium alloy leads to the formation of a superstructure with cadmium atoms around the edge of the plate-like zones which prevent their further growth. The structure of the zones in aluminium–copper alloys to which lithium and indium have been added was then described. The influence of cold work upon subsequent precipitation phenomena is a topic of great theoretical and practical interest. Miss Silcock reviewed some of the earlier investigations in this field and then described results she had obtained which indicate that prior cold work limits the number of orientations in which the θ′ phase forms on aging aluminium–copper alloys. Cold-worked aluminium–copper alloys containing cadmium behave in the same way as alloys free of cadmium, an effect which was attributed to an association between the cadmium atoms and the extra vacancies introduced during deformation.

The study of precipitation phenomena in steels has lagged far behind the work on light alloys. The main reasons for this are that X-ray techniques are not readily applicable to the early stages of the precipitation reactions since it is impossible to prepare single crystals of martensite, while at the later stages, bulk chemical extraction techniques followed by X-ray diffraction of the extracts serves only to identify the phases and gives no idea of the size, shape and distribution of precipitated particles. With the aid of extraction replicas and the electron microscope, the study of precipitation reactions in steels has greatly advanced, and recent results obtained in this field were described by Prof. R. W. K. Honeycombe (Department of Metallurgy, Sheffield). He described the morphological changes associated with the decomposition of martensitic plain carbon steels and then discussed the modifications introduced by the addition of strong carbide-forming elements, contrasting the different effects of chromium, molybdenum and vanadium, and the influence of small additions of niobium and tantalum. Precipitation in austenitic steels has not been studied in as great detail as that in ferritic materials, but Prof. Honeycombe described some new results on the formation of chromium carbides and niobium carbides in a standard creep-resistant austenitic steel.

The discussion which followed the principal papers was concerned mainly with the presentation of new results obtained by electron microscopy. Miss K. B. Day (British Aluminium, Gerrards Cross) put in a plea for the retention of the oxide replica technique for studying precipitation in aluminium alloys, illustrating the many advantages of the technique for investigating the advanced stages of precipitation reactions. P. M. Kelly (Cambridge) described how he had been able to prepare thin foils of steel from bulk material which were suitable for examination by direct transmission in the electron microscope. The results he obtained on high-carbon martensites and tempered plain carbon steels were illustrated. A film on precipitation in an aluminium–4 per cent copper alloy was shown by G. Thomas and M. J. Whelan (Cambridge). The film was obtained by aging thin foils of the alloy on a heating stage in the electron microscope and recording the structural changes as observed on the viewing screen with a cine-camera. The film showed conclusively that the final stages of aging involved the resolution of small particles and growth of large particles of the θ-phase.

A number of contributors presented results on the precipitation of vacancies in pure metals and alloys. R. E. Smallman (U.K. Atomic Energy Authority, Harwell) showed electron micrographs of the effects produced when vacancies were precipitated from nickel, copper, silver and gold and discussed the results obtained in terms of the energies of stacking faults in the respective metals. P. B. Hirsch (Cambridge) presented similar results and gave an account of the formation of tetrahedral stacking faults in gold. The formation of dislocation spirals by the condensation of vacancies on screw dislocations in an aluminium 4 per cent copper alloy was described by M. J. Whelan and G. Thomas (Cambridge). These spiral dislocations provide favourable sites for the nucleation of precipitates and are responsible for the structures shown by Mme. A. R. Weill (Paris) of abnormalities in the distribution of the θ′ precipitates after aging.

The object of the conference, in attempting to bring two groups of workers together, was admirably conceived; the fruits of this union will be awaited with interest. For the electron microscopists at least the agreement between their results and those obtained by X-ray diffraction was reassuring, and vindicated their efforts of the past few years in the development of the thin-foil techniques for the direct examination of metals by transmission.

J. Nutting

FUEL RESEARCH

THE report of the Fuel Research Board for 1957*, issued on October 31, 1958, is particularly noteworthy for the fact that it records the decision to close down the Fuel Research Station at Greenwich, and transfer to the new Warren Springs Laboratory at Stevenage only two main items of research. These are the programmes of work concerned with the measurement and abatement of air pollution and with the synthesis of oil from carbon monoxide and hydrogen, which are obtained from the gasification of coal.

In recent years quite a number of other organizations have also been concerned with research on fuels, most of them in connexion with more or less specialized aspects of fuel technology and its associated bearing on industrial practice.

The new laboratory at Stevenage is envisaged as the centre of research in Britain on air pollution, though again many aspects of the problem associated with processing must necessarily rest to some degree in the domain of other organizations. The co-operative scheme for the measurement of pollution together with the collection and analysis of the results will also be continued at Stevenage. A new and much required programme of research will be undertaken on the chemical reactions of pollutants in the atmosphere, and on dispersal and convective processes in the atmosphere.

An interesting feature of the report is the reference to the development of a small portable instrument, which is intended to be used in place of the Ringelmann chart. Those familiar with the Ringelmann method will recognize that it has never proved to be a really satisfactory means of assessing smoke pollution. In principle, the new instrument consists of a small telescope containing a number of translucent screens, darkened to standard shades, with which the smoke can be compared. The instrument is held so that the screens are seen against the same background as the smoke. It is easy to read, and consistent observations are obtained by different observers.

Another problem which has been investigated is the emission of exhaust gases from motor-vehicles, a nuisance familiar alike to motorist and pedestrian. In this case the effectiveness of a catalytic combustion unit has been examined and found to reduce substantially the concentration of carbon monoxide in the exhaust gas. The life of the catalyst, however, as would be suspected, is a limiting factor of usefulness, signs of deterioration having been shown after 11,000 miles.

There is an impression on the lay mind, arising perhaps from the magic associated with the development of nuclear energy, that a new scientific sun has arisen which will put out the candle of coal. As yet it may be wishful thinking. Our coalfields are still of great importance to Great Britain, and this situation must yet remain for a long time. Accordingly, the reference in the report to the continuation of work on the synthesis of oil from coal should be regarded as a timely reminder of the problems ahead. With the development of nuclear energy, the rapid spread both domestically and industrially in the use of oil, and the foreshadowed increase in the application of oil to the making of towns' gas, it is not possible to envisage a future surplus of low-grade coal of the kind now consumed by power stations. The total gasification of such coal into gaseous fuels suitable for distribution or for synthetic purposes is a matter to which serious attention should be given. It will need national support on a far more substantial scale than has been applied in the past. By this means alone can the sulphur problem in atmospheric pollution be solved. The reduction in the consumption of coal may before long become a major issue in fuel policy. We are approaching the situation in which we may see even remunerative collieries shut down, while at the same time attempting to sell exports in a highly competitive market in order to pay for imported fuels that have replaced the use of coal.

This statement may well be regarded as controversial, but to envisage the possibility is to take stock of the remedy. There is accordingly no less urgency in fuel research than there was when the Fuel Research Station at Greenwich was established in 1917, for as the field of activity has extended the problems have multiplied. In this way alone does technological advancement, so much needed in a modern world, take place.

R. J. SARJANT

THE METROPOLITAN WATER BOARD

REPORT FOR 1955–56

THE Metropolitan Water Board now distributes 322 million gallons of water daily, taking its raw supplies both from rivers and wells, treating them by a wide variety of processes and carrying out very extensive chemical, bacteriological and biological research to develop new methods of treatment and control and to maintain the safety and palatability of the finished product. The reports of the Director of Water Examination always contain a detailed and well-documented account of the quality control, and research, for which he is responsible. A large part of the bacteriological section of the present report* is concerned with the enumeration of bacteria, particularly of coliforms, by the method of multiple tubes and by membrane filtration. It has been shown that the membrane filtration technique is superior for the examination of some, but not all, types of water; it is, for example, now used as the standard method for the routine examination of all stored waters. It has been found that the membranes, which are somewhat expensive, can be re-used several times, and it seems possible that the method may eventually prove to be much cheaper in materials than the multiple tube technique previously employed. Another very useful piece of work described in this part of the report deals with the standardization and selection of bile salts and peptone—different samples of which differ considerably in their properties in the MacConkey test.

The biological section of the report is concerned mainly with the control of the growth of planktonic algae in reservoirs. A constant check is made of the numbers of these at different depths and of the concentration of nutrient substances in the water, and from this information the counter-measures to be used to prevent interference with the treatment plants are decided. It is sometimes possible to avoid trouble by altering the depth at which water is drawn from a reservoir; sometimes copper sulphate is added, though this always involves a considerable risk of failure and usually requires calm weather to be successful; and it is still necessary at times to take a reservoir out of service until an outburst of algae has died down. Hydrographic studies on the King George VI reservoir, together with experiments with models made in conjunction with the University of London, have suggested that the difficulties caused by thermal stratification, which limit the allowable depth, may not be so serious as had been thought and that it might be practicable and economic to induce vertical circulation of the water by pumping or by careful design of inlets. A differential temperature recorder for varying thermal stratification has been developed and has been tested in the field.

There is a further account of research on the sterilization of jute yarn, which is used for packing joints between pipes. It is now suggested that the yarn might be sterilized by the vapour of formaldehyde, being then treated with copper sulphate, iron alum, and sodium carbonate to prevent rotting.

A long section of the report deals with comparative tests with several large experimental plants (both upward-flow and horizontal-flow) on the clarification of water after coagulation with alum and activated silica; the effect of treatment on the filterability, bacterial count, chemical composition, and numbers of invertebrates and algae, has been studied in great detail. From results of large-scale experiments it is believed that it would be economic to recover alum for re-use from the sludge by drying it, calcining and treating with sulphuric acid.

B. A. SOUTHGATE

YIELD OF INFECTIVE 'RIBONUCLEIC ACID' FROM IMPURE MURRAY VALLEY ENCEPHALITIS VIRUS AFTER DIFFERENT TREATMENTS

By G. L. ADA and S. G. ANDERSON

Walter and Eliza Hall Institute of Medical Research, Melbourne

FOLLOWING the procedure of Gierer and Schramm[1], we have prepared an infective product by phenol treatment of crude suspensions of Murray Valley encephalitis virus from baby mouse brains. The infectivity of this product was destroyed by pancreatic ribonuclease (Worthington) and by normal rabbit serum, but in saline was more stable than virus. It seems that this product is essentially ribonucleic acid, although it probably contains other substances also. Following the practice of other workers[2], we have designated the product 'RNA'. For titration, virus has been diluted in 10 per cent normal rabbit serum in saline, and 'RNA' has been diluted in a phosphate citrate buffered saline at pH 7·1. Chick embryos 12 days old were inoculated on the chorioallantoic membrane with 0·05 ml. vol., and the lethal end-points were determined at 3 days.

In most respects, the 'RNA' of Murray Valley encephalitis virus behaved like the 'RNA' of other viruses recently reported. But in addition it was found possible to recover infective 'RNA' from crude virus which had been treated in various ways designed to reduce its infectivity considerably.

When crude virus with a titre of $10^{6\cdot7}$ was treated with 9 per cent phenol for 1 min., the resulting suspension had no infectivity. After subsequent treatment of this suspension with 90 per cent phenol, as in the standard method of Gierer and Schramm, infective 'RNA' appeared and reached a titre of 10^4–10^5 by the end of the extraction procedure.

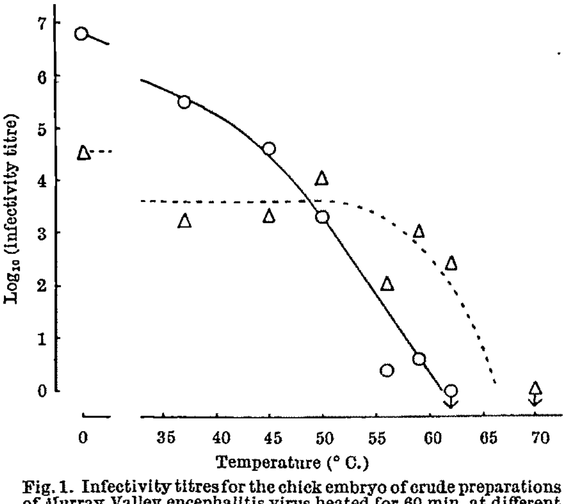

Fig. 1. Infectivity titres for the chick embryo of crude preparations of Murray Valley encephalitis virus heated for 60 min. at different temperatures and of the 'RNA' derived by phenol treatment from such heated virus
○, infectivity of heated virus; △, infectivity of ribonucleic acid derived from heated virus

Crude Murray Valley encephalitis virus lost infectivity on heating; for example, original virus with a titre of 10^7 was reduced in titre to $10^{1\cdot0}$ by holding at 56° C. and pH 7·1 for 60 min.; and after holding at 62° C. for 60 min. the undiluted preparation failed to infect chick embryos. The standard phenol procedure was applied to both these heated preparations and yielded samples of 'RNA' with infective titres of $10^{2\cdot0}$ and $10^{2\cdot7}$, respectively. These latter infectivities were lost on incubation with 1 μgm./ml. of ribonuclease for 20 min. at 15° C. A series of results of this type is shown graphically in Fig. 1. The normal ratio of titre of original crude virus to titre of 'RNA' derived from this virus was usually about 10^2 as titrated in eggs. For virus heated at or above 50° C. for 60 min. this ratio became less than 1.

Throughout the present work all titrations of infectivity were carried out in chick embryos, but it may be noted that if infectivities were titrated by inoculation of baby mice by the intracerebral route, normal virus titred at $10^{8\cdot2}$ and 'RNA' derived from it, at $10^{2\cdot8}$ $LD50$ per 0·01 ml. This V/R ratio ($10^{8\cdot2}/10^{2\cdot8}$) fell to $10^{2\cdot7}/10^{0\cdot5}$ for virus heated at 62° C.

Virus lost titre at a low pH. After standing at pH 3·0 for 30 min. at 20° C., a crude preparation of

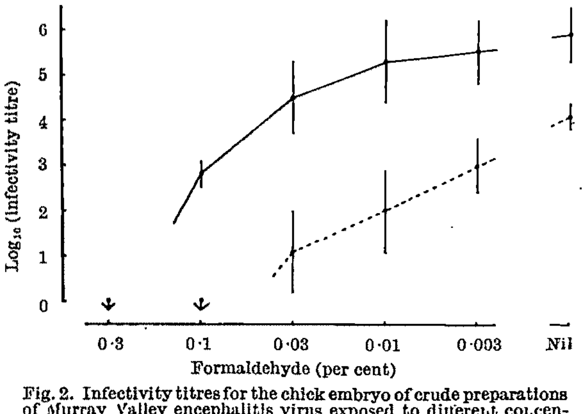

Fig. 2. Infectivity titres for the chick embryo of crude preparations of Murray Valley encephalitis virus exposed to different concentrations of formaldehyde for 195 min. at 20° C. and of the 'RNA' derived by phenol treatment from such treated virus. Each point is the mean value of between 4 and 10 experiments, the vertical lines representing the standard deviation
——, infectivity of treated virus; – – –, infectivity of ribonucleic acid derived from treated virus

virus with an original titre of $10^{6\cdot8}$ had a titre of $10^{3\cdot1}$, but on phenol treatment this then yielded 'RNA' with an infective titre of $10^{4\cdot8}$. Again, a virus preparation of original titre $10^{7\cdot0}$ had a titre of $10^{2\cdot8}$ after standing at *p*H 2; but then yielded 'RNA' with a titre of $10^{3\cdot5}$.

Attempts were made to extract infective 'RNA' from virus which had been treated with various concentrations of formaldehyde. Fig. 2 shows that concentrations of formaldehyde of 0·01 per cent or higher reduced the infective titre of a crude virus preparation over the period of 3½ hr. at 4° C. Crude virus treated with formaldehyde in the range of 0·003–0·1 per cent yielded relatively less infective 'RNA' than did control virus held at 4° C. without formaldehyde. Similar results were obtained even when the formaldehyde was neutralized with ammonia before the preparation of the 'RNA'.

Essentially the results with phenol, heat and low *p*H show that damaged crude preparations of Murray Valley encephalitis virus will yield 'RNA' with an infectivity for the chick embryo which may be greater than that of the preparation from which the 'RNA' is obtained. This does not hold for virus preparations damaged by formalin. Here the yield of infectivity in extracted 'RNA' is, on the contrary, unduly low.

Any interpretation of these findings requires a knowledge of the source of the 'RNA' within the crude virus preparation. For reasons based on experimental work to be reported elsewhere, we prefer to use as a working hypothesis the assumption that 'RNA' comes essentially from the infective virus particles. We also assume that the process of infection of cells involves as a necessary step the intracellular liberation of infective nucleic acid. On such a basis it is natural to suggest that heat, acid or dilute phenol acts by denaturing the surface protein, and that this makes intracellular biological liberation of ribonucleic acid from the infecting particle difficult or impossible but leaves much of the ribonucleic acid unaltered and capable of liberation by phenol treatment.

On the other hand, the effect of formalin would seem to be primarily on the ribonucleic acid[3] or on the mechanism of union between protein and ribonucleic acid in the particle. It appears that in this case the intracellular processes are more effective than phenol for the liberation of infective 'RNA'.

We would stress that the final interpretation of these results with crude virus must await the study of purified virus under comparable conditions.

CHROMOSOME MAPS OF *SACCHAROMYCES*

By PROF. CARL C. LINDEGREN, GERTRUDE LINDEGREN, ERNEST E. SHULT and SHARON DESBOROUGH

Biological Research Laboratory, Southern Illinois University, Carbondale

LINDEGREN AND LINDEGREN[1,2] reported linkage between two genes controlling histidine (*HI*) and anthranilic acid (*AN*) requirements in *Saccharomyces* and the five separate 'centromere markers': (1) the mating-type locus (α/*a*), the loci of genes controlling the syntheses of (2) *para*-aminobenzoic acid, (3) uracil, (4) adenine, and (5) the fermentation of galactose—and other linkages between genes controlling nutrilite requirements for inositol, pyridoxine and thiamine. In the lumped data from a number of small families (in which other tetrad distributions were not always consistent) the centromere linkages (α, galactose (*GA*), uracil (*UR*)) and the linkage of histidine (*HI*) to anthranilic acid (*AN*) (which was afterwards confirmed by Leupold[3]) were consistently repeated. A complete map (Fig. 1) was finally constructed when a recent series of nineteen large families (each of which was heterozygous for 8–19 loci simultaneously) totalling more than 1,184 asci (involving at least 10 'new' gene markers) were analysed. Bold-face type indicates markers the order of which has been repeated consistently in every family heterozygous for these genes, in spite of variations in the frequencies of crossing-over and interference in the different families. The genes are arranged on a scale roughly proportional to the average number of cross-overs per meiosis in all the families analysed.

(The recombination values are not measured in centimorgans but as the average number of cross-overs per meiosis, estimated by assuming a Poisson distribution of crossing-over in the absence of chromatid interference. The units of measurement will be called 'stranes'[4–6]. Stranes correspond closely to centimorgans over short distances but deviate markedly, becoming greater as the distances increase. Although stranes are not subject to an upper limit of 50, they are subject to a sampling error which increases rapidly, making higher values less reliable. The considerable 'shrinkage' distortion characteristic of maps based on centimorgans is avoided by the use of stranes. The principles on which this unit is established were laid down by Sturtevant (for linearity)[4], Trow[5], Haldane[6], Mather and Beale[7], Rizet and Engelmann[8], but the defence of the concept of interference by Sturtevant[4] and Muller[9] and later by Weinstein[10] discouraged American geneticists for many decades from exploiting methods for correcting recombination values. The view that such correction is possible has been recently revived by Papazian[11], Spiegelman[12] and Shult and Lindegren[13], and the results from tetrad analysis presented here appear to justify this view. The additivity of stranes (as shown by the complete results which will be presented in detail elsewhere) even at high values is much more precise than would be expected on the older views.)

Loci, the linkages of which appeared significant in only a few families, are written in light-face type to denote a lower level of certainty. The phenotypes of the gene symbols are indicated in Table 1.

MA controls the synthesis of maltase, which splits maltose and turanose but no other sugars, *MZ*

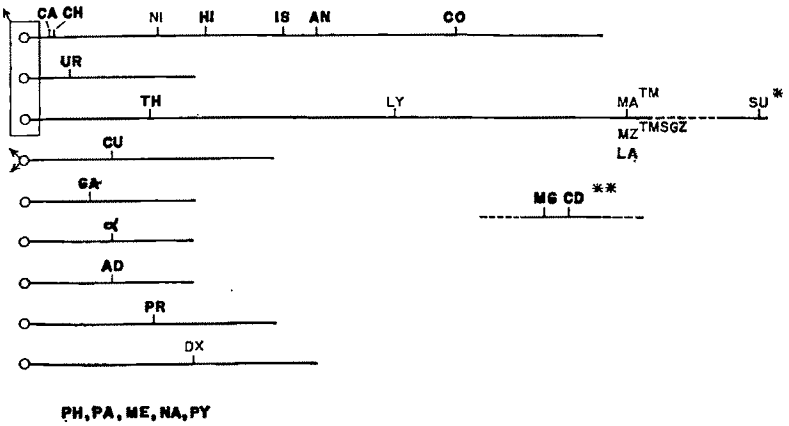

Fig. 1. Chromosome maps of *Saccharomyces cerevisiae*. Circles denote centromeres with the respective chromosome arms to the right. The box enclosing the first three centromeres indicates their preferential segregation to the same pole. The arrows on the *CU*-centromere indicate respective instances of 'coupling' and 'repulsion' of this centromere with those enclosed in the box. Gene symbols are defined in Table 1. Genes listed at the bottom of the map have not shown consistent linkages with other genes in these families; genes in light-face type show consistent linkage but appear in only a few families; genes listed in bold-face type have shown linkages consistent with the map arrangement in every family heterozygous for the genes

* The location of *SU* distal to the *MA* allele is strongly suggested by earlier data of Lindegren and Lindegren (ref. 24). ** This linkage group was established by Middlekauff, Hino, Yang, Lindegren and Lindegren (ref. 25) and Lindegren and Lindegren (ref. 26), but has not as yet been located

controls the synthesis of melezitase, which splits maltose, turanose, sucrose, methyl-α-D-glucopyranoside and melezitose together with a few other short-chained α-glucosides. The enzymes produced by *MA* and *MZ* are different since the maltase produced by *MA* will not split methyl-α-D-glucopyranoside, melezitose or sucrose. *LA* controls the splitting of lactose and is inferred from Kluyver's[14] rule that the fermentation of lactose in *Saccharomyces* excludes the fermentation of maltose and vice versa, which is the operational definition of an allele. A multiple series of alleles exist at the *MZ* locus, all controlling the synthesis of the same enzyme, melezitase, but differing from one another by the inductors to which they respond to effect the synthesis of the enzyme. It is suggested that the three major alleles are either very closely linked or are multiple alleles occupying a single locus.

Winge and Roberts[15], Gilliland[16], Hawthorne[17] and Douglas and Condie[18] have described isomeric genes controlling the synthesis of enzymes splitting carbohydrates or converting galactose into fermentable hexose. But the term 'isomeric' requires more specific definition. For example, there are three different genes in *Saccharomyces* which control different enzymes that split maltose; *MA*, *MZ* and *DX*. If 'isomeric' means genes which achieve the same result, then these genes are isomeric; if it means genes which are duplicates of each other at different locations 'isomeric' is a misnomer. A series of different (so-called 'isomeric') genes which are said to control the fermentation of galactose actually act only to change the rate at which a single primary gene produces its enzyme. According to the established conventional procedure, these genes are plus or minus modifiers of the primary gene *GA*, which is the only gene in *Saccharomyces* that has been demonstrated to respond to galactose by the production of an enzyme or an enzyme system which converts galactose into fermentable hexose.

Table 1

Symbol	Phenotype
α/a	Mating type
AD-1	Adenine requirement
AN	Anthranilic acid requirement (replaced by tryptophan)
CA	Resistance to 0·2–0·4 per cent caffeine
CH	Choline requirement
CO	Resistance to 1·0–2·5 per cent cobalt
CU	Resistance to (1–2) × 10^{-3} *M* copper
CD	Resistance to 0·01–0·02 per cent cadmium
DX	Fermentation of dextrin
GA	Fermentation of galactose
HI	Histidine requirement
IS	*iso*Leucine requirement
LY	Lysine requirement
ME	Fermentation of melibiose
NI	Resistance to 1–10 per cent nicotine
PR	Proline requirement (replaced by arginine)
TH	Thiamine requirement
MA	Fermentation of maltose
MZ	Fermentation of melezitose
LA	Fermentation of lactose

The genes for the nutrilite requirements nicotinic acid (*NA*), phenylalanine (*PH*), pyridoxine (*PY*) and pantothenic acid (*PA*) and a gene for the fermentation of melibiose (*ME*) (although regularly Mendelian) have to date shown no consistent linkage to any other genes. Introduction of 'new' genes may be expected to bring these 'unlinked' genes into the map.

Chromosome I, which has been well established by the analysis of numerous hybrids, comprises the additive linear sequence *CA*, *CH*, *HI*, *IS*, *AN*, *CO*. In each of 6 families (452 tetrads, Table 2) heterozygous for the markers *UR*, *TH*, *CH* (or *CA*) and any combination of the markers *HI*, *IS*, *AN* and *CO*, it was found that linkage group 1 'branched' into two arms carrying *UR* and *TH*, respectively. The tetrad distributions of the three centromere markers (*CH*, *UR* and *TH*) with other randomly segregating centromere markers (α and *GA*, Table 3) show that the point of 'branching' is identical with the centromere of Chromosome I, about 5 units from the tightly linked genes *CA* and *CH*. The marker *CU* constitutes a fourth directly linked branch (in 2 of the 6 families; 132 tetrads, Table 3), but reverse linkage (74 per cent recombination) of *CU* with *CH* (and other members of its linkage group) in one family of 180 tetrads,

established unequivocally that *CU* was located on a chromosome separate from *CH* and, in this case also, the point of 'branching' is identical with the centromere of Chromosome I. These results prove that the apparent branching of linkage groups results from preferential segregation of centromeres in parental combination and that reverse linkage results from preferential segregation of centromeres in non-parental combinations, a situation identical with that reported by Wallace[19] except that (1) the preference is nearly 100 per cent instead of 67 per cent and (2) the added advantage of tetrad analysis enables one to locate the centromere with precision[20,21]. These findings provide the first confirmation of the hypothesis[19,22] that the site of 'affinity' is the centromere.

It has not yet been possible to separate the 'branches' *UR*, *TH* and Chromosome I into two or three chromosomes, and, for this reason, they are represented tentatively as three separate chromosome arms preferentially segregating to the same pole, with the reservation that two of the arms may be opposite arms of the same chromosome. From the linkage results, it is inferred that the haploid number of chromosomes in *Saccharomyces* is at least seven. This disparity with the finding of McClary, Williams, Lindegren and Ogur[23] reflects the difficulties inherent in the cytological analysis of micro-organisms, especially when the problem of size is further complicated by the synapsis of non-homologous centromeres.

DIFFERENTIAL DISTRIBUTION OF RADIOACTIVE STRONTIUM AND YTTRIUM IN THE TISSUES OF THE RABBIT'S EYE

THE maximum permissible level of body burden for each radioactive material depends on knowledge of (or assumptions about) the tissue in which the material is chiefly concentrated. Retention has been investigated experimentally in the major tissues of the body[1], such as bone, bone marrow, muscle, liver, but specialized organs of proportionately small bulk have hitherto been ignored except in the case of the thyroid gland. When the toxicity of radioiodine was first considered, the thyroid was not overlooked because its ability to concentrate iodine was already well known. Fission products, however, consists largely of elements about which little is known physiologically, and not much consideration seems to have been given so far to the possibility that radioactive materials other than radioiodine might be concentrated in specialized organs, to such an extent as to be of importance in determining their maximum permissible level. Biological concentration due to specialized metabolic processes is the major unknown in assessing the hazards of radioactive isotopes of trace elements, that is, of fission products.

Table 1. Concentration of Strontium-90 (mean ± *S.E.*) in Components of the Rabbit's Eye as Fractions × 10^4 of the Concentration in the Femur of the same Animal (Equilibrium Values)

Time since injection of strontium-90	7–8 hr.	1 day	3 days	9 days	30 days
No. of animals	3	5	3	4–5	7.
Iris with ciliary body	110 ± 20	83 ± 4	69 ± 6	51 ± 5	42 ± 5
Choroid	130 ± 30	82 ± 8	56 ± 0·4	29 ± 5	22 ± 3
Retina	57 ± 12	39 ± 5	25 ± 6	12 ± 2	5·3 ± 0·9
Cornea	140 ± 30	50 ± 3	24 ± 3	10 ± 1	7 ± 1
Sclera	120 ± 20	48 ± 2	24 ± 4	11 ± 1	7·6 ± 1·2

Striated muscle	36 ± 6	12 ± 1	5·6 ± 0·9	2·7 ± 0·3	2·4 ± 0·6
Femur (μc./gm. divided by μc. injected/gm. body-weight)	14·0 ± 1·2	10·3 ± 2·0	10·1 ± 1·5	6·3 ± 1·1	3·5 ± 0·3*

* Excluding No. 1012, which died (see Table 2) and had a femur value of 13.

In different species of mammal, physiologically remarkable concentrations of elements such as zinc, barium or strontium may be found in the eye[2], which suggests that their radioactive isotopes will also be concentrated there. This deduction is confirmed by the observations on strontium-90 reported here. The toxicological significance of the results depends not only on the relative radiosensitivities of bone and of such components of the eye as iris, choroid and retina, but also on the marked differences between species in the way in which many elements are concentrated in these parts of the eye.

Several fission products of the first importance from the point of view of hazards to health consist of pairs of radioactive materials, for example, strontium-90 – yttrium-90, barium-140 – lanthanum-140, cerium-144 – praseodymium-144. In each of these cases the radioactive daughter has a half-life much shorter than that of the parent element, and in most toxicological studies the equilibrium values in tissue are all that is determined. The observations reported here, however, show that, in the case of strontium-90 – yttrium-90 in the retina, ignoring the metabolic disequilibrium of radioactive parent and radioactive daughter may lead to an under-estimate of the hazard, possibly by as much as an order of magnitude.

Weanling rabbits aged 6–8 weeks were injected intravenously (J. V.) with an equilibrium mixture of strontium-90 and yttrium-90 or with yttrium-91 in doses of between 72 and 600 μc./kgm. body-weight, and killed at various intervals of time thereafter. The rabbits were maintained throughout on a standard regime[3]. Some animals were given a daily dose of strontium-90 by mouth as described elsewhere[4]. The solutions of strontium-90 – yttrium-90 and of yttrium-91 given to the rabbits were each contaminated to less than 1 per cent by other radioactive materials.

The eyes were removed when the animal was killed and transferred to a separate laboratory for dissection into their various parts, each of which was weighed (A. P.). Some eyes were dissected unfixed, some after fixation in alcohol. In the rabbit, the iris and ciliary body cannot be separated. In most cases the parts from the two eyes were combined to make one specimen. The specimens were then transferred to a third laboratory where they were dissolved in nitric acid; the solutions were made up to 10 ml. or multiples thereof, and the count-rate (hereafter abbreviated to count) determined in a Veall-type *M6H* counter (R. H. M.). Appropriate corrections were made for background and lost counts and, when many repeat counts were made, for transfer losses. The geographical separation of the laboratories was an advantage in minimizing possible contamination of specimens, most of which weighed between 10^{-4} and 10^{-5} of the body-weight.

In order to determine the strontium-90 content, at least two counts were made of each specimen, not less than a week apart, the first of these being not less than 3 weeks after dissolving the tissues in acid. After 3 weeks, yttrium-90 (half-life 64 hr.) and strontium-90 (half-life 28 years) are effectively in radioactive equilibrium. Counts of a standard solution of known concentration were made each time a series of specimens was counted so that the observed counts could be converted to microcuries and the tissue concentrations of strontium-90 or of yttrium-90 determined in μc./gm.

Many specimens were counted on one or more occasions before radioactive equilibrium had been reached. A quantitative assessment of the excess or deficiency of yttrium-90 was made by subtracting the final equilibrium counts from the earlier counts and plotting the differences on semi-logarithmic graph paper[5]. The rate of decay or growth of counts was within ± 10 per cent of that expected for yttrium-90 in all but three specimens, and in two of these was not far outside these limits. The counts from the third were discarded. The initial count which would have been expected if the tissue had been counted simultaneously with the death of the animal was determined by extrapolation, using the theoretical half-life for yttrium-90. Since the counters used were sensitive to yttrium-90 (efficiency 10–11 per cent) and insensitive to strontium-90 (efficiency 0·5 per cent), the observed counts were practically all due to yttrium-90. Thus the ratio of the initial count to the final equilibrium count gave the yttrium-90 at the moment of death as a fraction of the yttrium-90 at equilibrium. Since at radioactive equilibrium 1 μc. of yttrium-90 is equivalent to 1 μc. of strontium-90, this ratio is also equal to the ratio of μc. of yttrium-90 to μc. of strontium-90 in a tissue at the moment of death.

When the interval between death of the animal and the first count was long, or when only one pre-equilibrium count was available (Table 2), the identity of yttrium-90 could not be proved, and the accuracy of determination of the expected initial count was low. Also, the closer the first count to the final equilibrium count the less accurate the determination of their difference, so that the exact value of the yttrium-90/strontium-90 ratios near 100 per cent must be uncertain, although the fact that equilibrium was nearly complete is, of course, sure.

The equilibrium concentration of strontium-90 in different tissues, expressed as a fraction of the injected dose per unit body-weight at different times after a single injection, is shown in Fig. 1. The scatter of the

† The values in parenthesis are very uncertain because the count-rates in the specimens amounted to only a small fraction of the background.
‡ This animal died during the night and this time is uncertain by ± 8 hr.
§ The strontium-90 content of this cornea was exceptionally high (? contaminated, ? correlated with age of animal).

results is reduced if the tissue concentration is expressed as a fraction of the concentration in the whole femur of the same animal (Table 1).

Different parts of the eye differed several-fold in their uptake and retention of strontium-90. The pigmented parts of the eye, iris with ciliary body and choroid, showed the highest concentration at all times after the first hour. Cornea and sclera came next, followed by retina and then vitreous. As might have been expected the concentration in the lens was least of all, from one-fifth to one-tenth of that in the vitreous. The concentration in striated muscle, a representative soft tissue, was intermediate between vitreous and lens.

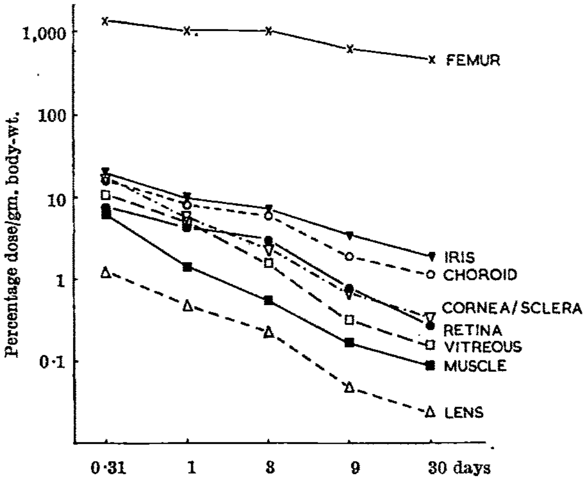

Fig. 1. Strontium-90 in bone and in the tissues of the eye of the rabbit
Abscissa, time in days after single intravenous injection; ordinate, strontium-90 in μc./gm. of tissue expressed as percentage of μc. injected/gm. body-weight. Both scales logarithmic
The values for cornea and sclera are so similar that they have been plotted as one

There was a 10–50-fold drop in concentration of radiostrontium in the different parts of the eye 7–8 hr. to 30 days after injection. Although between 9 and 30 days the absolute levels decreased by about a half (Fig. 1), their ratio to the concentration in the femur changed much less (Table 1). After the initial phases of redistribution, therefore, the strontium-90 was as fixed, or as mobile, depending on the point of view, in the soft tissues of the eye as in the bone.

The concentration of stable strontium has been determined in the different parts of the rabbit's eye, dissected in the same way[3]. The relative proportions of radiostrontium in the different tissues at 9–30 days were similar to their relative content of stable strontium, though with a wider range in values than for stable strontium.

In two rabbits at 3 months and one at 6 months after injection a broadly similar pattern for the concentration of strontium-90 was found. The discrepancies observed may possibly be due to the fact that the counting-levels at these time-intervals were low and the results consequently uncertain.

Table 2 gives the results on the equilibrium between yttrium-90 and strontium-90 at the time of death as deduced by the method described. All parts of the eye showed an increase in the ratio of μc. yttrium-90 to μc. strontium-90 during the first three days after injection. The cornea and vitreous showed a marked deficiency in yttrium-90 at all times but by three days after injection choroid, retina, sclera and muscle contained a definite or marked excess of yttrium-90. A persistent excess was found only in the retina.

When strontium-90 with yttrium-90 in equilibrium was fed daily the order of activity concentration in the different parts of the eye was the same as 1–30 days after a single injection. The cornea and vitreous were again relatively deficient in yttrium-90 (Table 2), the lens and iris were nearly in equilibrium, while the choroid and sclera showed a definite excess of yttrium-90. This excess, however, was most

Table 3. CONCENTRATION OF YTTRIUM-91 IN COMPONENTS OF THE RABBIT'S EYE 11 DAYS AFTER ADMINISTRATION (μC./GM. TISSUE AS PERCENTAGE OF μC. INJECTED/GM. BODY-WEIGHT) AND COMPARISON OF YTTRIUM-91 WITH STRONTIUM-90 AND YTTRIUM-90

	Concentration of yttrium-91 at 11 days			11-day values in rabbits given strontium-90 + yttrium-90		
	Rabbit No.				Yttrium-90	
	986 (killed)	987 (died)	Mean	Strontium-90 (estimated from results of Fig. 1)	(derived from strontium-90 values together with results of Table 2)	(contribution expected from yttrium-90 injected*)
Iris with ciliary body	5·2	17·6	11	3	3	1

Cornea	0·06	0·45	0·3	0·7	0·2	very small
Muscle	6·7	4·1	5·4	0·16	0·2	0·3

* Assumed to be one-sixteenth of mean yttrium-91 value because the injected yttrium-90 would have decayed to one-sixteenth of its original level after 11 days (see text).

pronounced in the retina, where μc. yttrium-90 per gm. averaged eight times the equilibrium value.

Two rabbits were given single injections of yttrium-91 and were examined 11 days later. The tissue concentrations of yttrium-91 were the same as those of strontium-90 in the retina, lens and cornea, but four times higher in the iris and 20–40 times higher in choroid, sclera and striated muscle (Table 3). The vitreous was the only tissue with less yttrium-91 than strontium-90. Thus the difference in retention between different parts of the eye was greater for yttrium-91 than for strontium-90. The difference in concentration of yttrium-91 between retina and choroid is especially noteworthy: it is impossible to make an absolute separation between them when dissecting the eye, and the relatively small amount of yttrium-91 in the retinal specimens may well have been wholly derived from adherent fragments of choroid.

In studying the results it must be understood that the yttrium-90 formed by the radioactive decay of strontium-90 cannot be expected to behave chemically or physiologically in the same way as radiostrontium. Strontium is one of the divalent alkaline-earth metals. Yttrium is trivalent and behaves like the rare earths. The two elements form compounds of different solubilities which may well influence their rates of diffusion, and their physiological behaviour is also different. Both elements are concentrated in bone, though in different sites[6], but yttrium, unlike strontium, may also be retained in soft tissues, particularly the liver, stomach and spleen[7]. A similar preferential uptake of injected yttrium-91 as compared with injected strontium-90 was found in sclera, choroid and iris with ciliary body (Table 3).

The slower diffusion of yttrium as compared with strontium is clearly shown by the deficiency of yttrium-90 in the avascular tissues, cornea, vitreous and lens, as compared with the other parts of the eye during the first 24 hr. after injection of an equilibrium mixture of yttrium-90 and strontium-90 (Table 2). Without knowledge of the relative blood levels of radiostrontium and radioyttrium it is not possible to decide whether there is any difference in the rate of penetration into the other parts of the eye.

The relative excess of yttrium-90 from 1 to 9 days after injection in all the other parts of the eye is perhaps most simply explained by the combined effect of two factors: (1) the fact that the concentration of radiostrontium in the tissues fell during this time interval, (2) the assumption that yttrium is not easily lost from a tissue once it is deposited there, as evidenced by the very high concentration of yttrium-91 as long as 11 days after its injection (Table 3). It is known also in the case of bone that, though retention of yttrium-91 may be of the same order as that of strontium-90 up to 7 days after injection[6], over a period of 6 months the loss of yttrium-91 is less[8]. A fall in the concentration of strontium-90 in a tissue due to outward diffusion from the cells must lead to a relative excess of yttrium-90 if the yttrium cannot diffuse outwards so easily. The rate of change of the level of strontium-90 in tissue decreased with time after injection and correspondingly the excess of yttrium-90 should have decreased progressively from 3 to 30 days, as was seen in sclera, choroid, cornea and muscle (Table 2). When the rate of change of concentration of strontium in tissue is slow compared to the rate of decay of yttrium-90, as at 30 days after injection, a difference in the rate of diffusion between strontium and yttrium would not be detected in this way.

The values for yttrium-90 at the earlier time-intervals will certainly not depend wholly upon yttrium-90 generated from strontium-90 within the body of the rabbit. The injected solution was an equilibrium mixture of strontium-90 and yttrium-90 so that the rabbits given strontium-90 were also injected with yttrium-90. This injected yttrium-90 would be expected to distribute itself just like the yttrium-91 since both isotopes were in the same chemical form when injected. A comparison may be made at 11 days after injection (Table 3) when the activity of injected yttrium-90 will have decayed to one-sixteenth of its original level (eleven days equal four half-lives of yttrium-90). At this time the contribution of injected yttrium-90 to the values observed for that radioisotope will be one-sixteenth of the mean values for yttrium-91 when tissue concentrations are expressed in the same units (fractions of injected dose per unit body-weight). The results in Table 3 show that direct uptake of yttrium-90 injected would contribute significantly to the observed levels of yttrium-90 11 days after injection in muscle, sclera, choroid and iris with ciliary body but not in retina, cornea, vitreous and lens. Some or all of the relative excess of yttrium-90 over strontium-90 in muscle, sclera and choroid at 3–9 days after injection (Table 2) may therefore be due to direct uptake of injected yttrium-90. At 30 days there was no excess of yttrium-90 in these tissues but by 30 days the radioisotope injected would have decayed by eleven half-lives and so would not contribute measurably to the amount observed in the tissue.

None of the factors already considered can account for the excess of yttrium-90 in the retina 30 days after injection of strontium-90; this excess can only come from yttrium-90 liberated from or generated within the tissues. The results in the retina at earlier times were also exceptional. There was a large excess of yttrium-90 at 3–9 days, even though the direct uptake of yttrium-91 was low at 11 days, and this excess changed relatively little with increase in time after injection of strontium-90 from 3 to 30 days. A similar excess of yttrium-90 was not found in the grey or white matter of the central nervous system. If yttrium cannot diffuse into or out of the retina, then the maximum possible amount of yttrium-90 in the retina at a constant blood level of strontium-90 is the equilibrium amount, whatever the rate at which strontium can diffuse into and out of the retinal cells. The yttrium-90 observed 30 days after injection, when the blood level must have been very stable, was certainly greater than this (Table 2). The excess of yttrium-90 was still larger in animals fed daily on strontium-90.

There is the possibility that the retina in animals given strontium-90 did not behave in the same way as in animals given yttrium-91, that is, in one set of animals radiation damage altered the ability of the retina to accumulate yttrium directly. The dosage of yttrium-91 was a little greater than that of strontium-90, it is true, but no difference was noted over a several-fold range in dosage of strontium-90 (Table 2). Thus, if there was radiation damage to the retina, it was in the animals given yttrium-91, and this does not affect the conclusion from the results of Table 2, namely, that the equilibrium count in a tissue containing radioactive parent and daughter isotopes may markedly under-estimate the radiation dose received by that tissue.

The yttrium-90 in the retina in excess of the equilibrium value must therefore originate in yttrium-90 liberated from other tissues laden with strontium-90 or yttrium-90, and there must be something in the retina which is capable of binding this yttrium-90 when it reaches the retina. Injected yttrium-91, however, was not bound by the retina even though it must have reached the eye, as was shown by its high concentration in choroid, iris and sclera. Presumably the chemical form and hence biological behaviour of yttrium liberated continuously from strontium-90 within the body is not necessarily the same as in the solutions of yttrium-91 or strontium-90 plus yttrium-90 used for injection. The retina thus behaves like many other soft tissues where the direct uptake of yttrium varies markedly with the chemical form in which the yttrium is administered[7]. It will be of interest to identify the chemical form in which yttrium-90 is liberated from tissues into the bloodstream, and which is selectively taken up by the retina but apparently not by the other tissues of the eye.

From 1 day after injection and thereafter the concentration of strontium-90 in the iris with ciliary body, the most radioactive part of the rabbit's eye, was always less than 1 per cent of the concentration in bone in the same rabbit. If it is considered that the harmful effects of radiation are due to its direct action on irradiated cells, the bone would have to consist of less than 1 per cent cells before a given mass of iris would have as great a chance of being damaged as the same mass of bone. Other factors needing consideration are the difference in bulk of bone and eye (if the harmful effect is due to the probability of change in any cell in the organ), the intrinsic radiosensitivity of bone and iris, and for particles as energetic as the β-particles of strontium-90 and especially yttrium-90, the geometrical distribution of dose in a complex organ like the eye where thin layers of tissue concentrate radioactivity to differing degrees. Clearly, existing information on all these points is too slight for any useful theoretical comparison of the eye and the bone as 'critical tissues' for strontium-90. No clinical observations of damage to the eye seem to have been made in experimental animals after administration of strontium-90 in doses sufficient to cause bone tumours.

The experimental result which may have important toxicological implications is the large excess of yttrium-90 in the retina of rabbits given strontium-90, especially after chronic administration. This accumulation of yttrium-90 would not have been predicted from the experiments made with yttrium alone; on the contrary, it would have been denied (Table 3). In principle, therefore, whatever the explanation of the findings may be, similar unexpected accumulations of radioactive daughter products may occur whenever cells are permeable to a radioactive parent element, and may not be detected unless special search for the excess of daughter is made. In the eye it is relatively easy to separate physiologically different parts and to show how differently they behave in this respect. In a geometrically complicated organ, like bone, it has not yet been possible to separate the physiologically different components and examine them separately for excess or deficiency of yttrium-90, and no method of specimen preparation which is long compared with the half-life of yttrium-90 can hope to be successful.

In addition to the strontium-90 – yttrium-90 decay chain, other decay chains which need consideration are barium-140 – lanthanum-140, cerium-144 – praseodymium-144, tellurium-132 – iodine-132 and the natural radium, thorium and uranium series. Tellurium – iodine has been carefully considered (G. E. Harrison, personal communication, 1957), but no information is available about possible disequilibrium between barium and lanthanum or cerium and praseodymium. Each natural radioactive series is composed of a number of different chemical elements, and there is clearly a possibility that unexpected concentrations of short-lived intermediate products may occur in some tissues. The physical dimensions of a specialized organ in which an α-emitter is concentrated are likely to be of little importance in determining the tissue dose, at least as compared with energetic β-emitters.

It is interesting that both the iris and choroid of dogs given radium or mesothorium or radiothorium show pathological changes. Plutonium is less effective. The iris becomes depigmented and there is a loss of iridescence in the fundus of the eye due to changes in the tapetum lucidum with development of an albuminuric choroiditis in some dogs[9]. The concentration of radium retained in the eye is more than thirty times that in plasma and most of this is in the eye tissues rather than in the fluids[10]. These elements may be concentrated in the dog choroid in some analogous way to zinc, the concentration of which in this tissue is 8·8 mgm./gm. dry-weight[11]. The iris of dogs receiving strontium-90 daily for many months may also lose its pigment[12].

Animal experiments may give invaluable evidence about the metabolic pathways of toxic materials; but they cannot give quantitative information about tissue retention in man. It has often been supposed that if the relative concentrations of the stable isotopes of different elements in human tissues were determined, the results would give quantitative information about the relative concentrations to be expected in different tissues if men were chronically exposed to radioactive isotopes of the same elements. Perhaps because such a principle seems self-evident, no experimental verification seems ever to have been attempted. Some observational support for the principle may be found in the general similarity between the relative concentrations in different parts of the rabbit's eye of strontium-90 as reported here, and of stable strontium as found by Sowden and Pirie[2]. The concentration of stable strontium in human bone is known[13], and if its concentration in rabbit bone is similar, as the concentration in the eyes of the two species is[2], the results reported here may be directly applicable to men.

Summarizing: (1) All parts of the rabbit's eye, except the lens, accumulated strontium-90 to a greater degree than striated muscle, a representative soft tissue. The pigmented parts accumulated most, the iris with ciliary body having 0·5 per cent of the concentration in the femur at 9–30 days when redistribution was approaching completion.

(2) There were much bigger differences between physiologically different parts of the eye in their retention of yttrium-91 than in their retention of strontium-90.

(3) Yttrium-90 and strontium-90 were rarely in equilibrium in any part of the eye at any time after administration of an equilibrium mixture. The retina maintained the largest excess of yttrium-90, especially after daily administration of strontium-90, although its direct uptake of yttrium-91 was small. This difference may be due to a difference in chemical form between the yttrium-91 injected and the yttrium-90 liberated within the body.

(4) Unexpected accumulations of radioactive isotopes of trace elements may be found in specialized organs of small bulk. These may then need consideration in setting maximum permissible levels.

Thanks are due to Mr. T. E. F. Carr for standardizing a solution of strontium-90, to Mr. R. H. Watts for technical assistance, and to Miss E. Flynn, Mr. G. Herring and Mrs. E. Ramsden for helpful discussions.

A CHEMICAL BASIS FOR THE CLASSIFICATION OF GLUME COLOUR IN NIGERIAN CULTIVATED SORGHUMS

By W. R. STANTON, T. B. MILLER and D. L. CURTIS

Regional Research Station, Ministry of Agriculture, Samaru,
Zaria, Nigeria

IN Nigerian sorghums the phenotypic expression of glume colour ranges from black through shades of mahogany and red to straw. An objective description of these colours would be of value in the classification of sorghum types[1], and accordingly a preliminary investigation of the chemistry of these pigments has been undertaken.

The material was obtained from a sample survey carried out in Northern Nigeria during 1957–58. Most sorghums mature after the rains, in November and December, and samples were collected during the dry season when the aerial relative humidity values rarely exceed 40 per cent and are often very much lower. Although it is known that grain and glume colours do fade over long periods, no changes were observed in the material received early, and it is unlikely that samples received later had altered since their collection.

Milled samples of the dried glume tissue were extracted with 0·1 *N* hydrochloric acid and examined according to the scheme of Robinson and Robinson[2] for the identification of flavonoid pigments. On extraction with amyl alcohol the pigments passed into the organic phase. Hydrolysis with 12 *N* hydrochloric acid did not alter the partition between amyl alcohol and water.

One-dimensional paper chromatograms were run on ethanol extracts obtained after 4-hr. extraction in a Soxhlet apparatus. The chromatograms were developed by the descending technique using butanol/acetic acid/water (4 : 1 : 5). Attempts to purify the extract with ethyl acetate failed to improve the development and tended to alter the relative intensities of the spots.

Fig. 1 illustrates the type of chromatogram produced. Up to three discrete spots occur with the following R_F values: spot 1, 0·76–0·80 blue-purple; spot 2, 0·89–0·93 red; spot 3, 0·95–0·99 brown.

All samples, other than 'straw' and 'white', so far examined gave spots 1, 2 and 3 or 2 and 3. No spots were visible with R_F values below 0·76 in the visible or in ultra-violet light. Treatment with ammonia intensified all spots and examination under ultraviolet did not assist differentiation appreciably.

As control pigments, extracts of fresh petals from *Pelargonium zonale* Ait. and *Petunia hybrida* Vilm. (purple) were used. The pelargonidin and petunidin spots showed R_F values corresponding to those reported by Geissman[3]. Extracts from pigmented glumes of millet (*Pennisetum typhoides* Stapf. and Hubbard) produced a blue spot of R_F 0·52. Extracts of this pigment with 0·1 *N* hydrochloric acid showed

rep. = replicate

a partition in favour of the aqueous phase on treatment with amyl alcohol. After hydrolysis this partition was reversed.

These findings suggest that the pigment in millet glumes is a glycoside and that those of sorghum are aglycones. The R_F values of aglycones tabulated by Bate-Smith[4] tend to be higher than the values for the corresponding glycosides. It is conceivable that the glycosides in the glumes of sorghum have undergone glycolysis during maturation and storage of the plant material.

In Table 1, the distribution of pigments, as designated by spots 1, 2 and 3, is illustrated for nineteen different samples. The apparent differences in intensity have been shown on a plus scale. The homogeneity of the results from within groups indicates that differences in level are real, though the effect of maturity and other factors in the differences precludes an interpretation of the results on a quantitative basis. The glumes from replicate heads of three samples, *ZA* 87, *ZA* 91, and *AD* 1, are given to illustrate the reproducibility of the chromatographic analysis within a sample. The table also incorporates the local names, glume colours according to the Quinby terminology and the agronomic groupings devised by Curtis[5] from a modification of Snowden[6]. It will be seen that the most striking and conclusive feature of the chromatographic analysis is the presence or absence of the blue spot 1. This appears in all black and in the so-called dark mahogany samples. Variation occurs in the intensity within groups of spots 2 and 3, but this requires further examination. Pigmentation does not appear to be completely absent in the straw-coloured varieties though spots 2 and 3 appear only after considerable concentration of the extract.

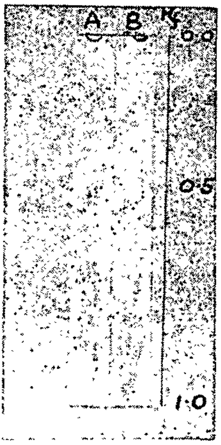

Fig. 1. Typical chromatograms photographed by reflected light. *A*, 'black' (*NG* 119); *B*, 'red' (*PL* 11)

It is not possible at this stage, for reasons given above, to correlate the results with quantitative effects of gene action. On the basis of the blue spot 1 samples can be differentiated into two main groups. The chemical analysis provides an objective classification of samples the glume colours of which range from black through purplish-black and dark mahogany to mahogany. There is no evidence, so far, that the pigment system varies in different groups of Nigerian sorghum. The chromatograms obtained from samples in the different subseries of Snowden are strikingly similar.

The work reported in this communication represents part of a taxonomic survey of sorghum varieties which is being conducted by two of the authors (W. R. S. and D. L. C.). Acknowledgment is made to the Northern Nigeria Ministry of Agriculture for permission to publish these observations.

Recording Radio Signals from Earth Satellites

Systematic recordings of radio transmissions from an Earth satellite for examination of the ionosphere can be used for providing also, for that particular observing site, the orbit data necessary for the prediction of transit times and the computation of ionospheric influences. For this purpose Doppler frequency shift measurements are particularly useful, and a system has been developed in this Laboratory whereby, with relatively simple equipment, the necessary information from 1958 δ 2 (*Sputnik III*) can be recorded simultaneously with the intensity variations which were previously reported[1]. The intensity variations and frequency samplings are displayed on adjacent cathode-ray tubes and photographed on 35-mm. film moving vertically at a speed of 6 in. per min. A beat-frequency oscillator is used in the receiver and the audio output applied to the horizontal deflexion plates of a cathode-ray tube without a time-base to give a record of the intensity variations as shown at *A* in Fig. 1. The pulse modulation of the transmission is clearly defined, but the 'fading pattern' is also well delineated.

For frequency sampling the same receiver output is applied to the circuitry of the other cathode-ray tube both to trigger a 'single shot' time-base (of adjustable speed and duration) which fires at a pre-set threshold, and simultaneously to apply a vertical deflexion of adjustable size. The result is a series of traces showing the frequency and wave-form of the incident signal as seen in Fig. 1*B*. An adjustable delay allows the time-base to fire at intervals sufficiently long to obviate overlapping of the samples. An audio signal—in this case 500 c./s.—is applied to the cathode-ray tube automatically each minute to serve as time marker and frequency calibration. The adjustments are such that one cycle on the record represents 100 cycles of beat frequency for ease of scaling.

The central line on the record in Fig. 1 is the recorded modulation of Station *WWV* applied on a neon indicator from a separate receiver as a time check.

The total 'Doppler shift' of the 20,005 Mc./s. frequency is of the order of 1,000 cycles, so that the full frequency-range can be covered at good sensitivity while still maintaining reasonable selectivity. In an improved version of the recorder four cathode-ray tubes are used, enabling simultaneous recording of the frequency and intensity variations of the second harmonic as well as the fundamental frequency. Alternatively, two additional intensity recordings can be made as, for example, on two other aerial systems. A more accurate system of time marking has also been incorporated.

This recording system has many good features in addition to its simplicity: it will give a satisfactory sampling on a keyed transmission and through quite severe noise and Morse interference; the wave-form of the received signal is obvious on inspection of the record so that multiple or indirect paths are clearly indicated; the experimental accuracy of the frequency determination can be increased to any extent required by adjustments to the time base, oscillograph and camera; the receiver frequency is crystal-controlled so that, if the transmitter frequency stability is good, as indicated in this case by the consistency of results, the frequency at the central inflexion point will be the actual transmitter frequency and will indicate the time of closest approach; the audio signal can be heard and the frequency display can be observed visually during the recording to give an immediate check on this time; a switch operated by a spring lock adjusted to the local transit period of the satellite makes the recording completely automatic subject to re-setting once a day; the records are easily analysed and the results plotted by relatively unskilled staff; the time of closest approach is established also for the intensity record, facilitating interpretation of the pattern.

With a series of records taken in this way it is possible to smooth out many of the deviations which occur in practice due to transmitter variations, ionospheric irregularities and recording limitations. In a Doppler record of a single transit the feature which can be derived most accurately is the slope of the Doppler-shift curve, $\partial F/\partial t$, at the point of closest approach, a particularly useful quantity for computation. From the values for a series of transits on a number of successive days it is possible to deduce the true value for an overhead transit, which again is a simple case for computation, and also the location of the other transits with reference to the overhead position.

The rate of change $\partial F/\partial t$ has a unique value depending on the height h and velocity V of the satellite and D, the angle between the orbital plane of the satellite and the corresponding zenithal orbital plane.

It is therefore possible from the information obtained above to derive Vh curves for the overhead case and one other defined transit, and the intersection of these curves will establish the velocity and height of the satellite. Derivation of the necessary curves has been simplified by the use of the *Silliac* electronic computer in the University of Sydney. The values compare satisfactorily with those obtained by other means.

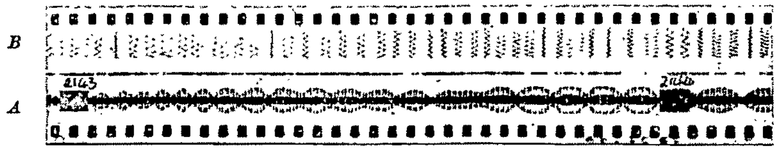

Fig. 1. Record of signals from Satellite 1958 δ 2 (*Sputnik III*). *A*, Intensity; *B*, frequency

Ionospheric effects are more noticeable on the intensity record as changes in the fading pattern. These recordings have been carried out consistently since the end of August, in which time the orbital plane has rotated more than 360°, so that each transit has been observed in both day and night conditions. Analyses are now in progress to examine the effects on the transmission of the variation in satellite height and of seasonal, diurnal and irregular changes in the ionosphere.

This work is the result of a combined effort by the staff of this Laboratory.

The Samoan Artificial Aurora

CULLINGTON[1] has recently reported the observation of an aurora-like phenomenon to the south-west of Apia (Samoa) which appears to have been produced by charged particles arriving along lines of force from the site of an atomic explosion, at great altitude in the neighbourhood of Johnston Island, some 2,000 miles distant. The interpretation of this phenomenon has been discussed in some detail by Fowler and Waddington[2] and by Kellogg, Ney and Winckler[3]. Since the particles are clearly guided by the Earth's magnetic field, the impact point for the particles, if we neglect the small drift in longitude, corresponds to the magnetic conjugate point for Johnston Island.

If the geomagnetic field was of purely dipole character, this conjugate point could be obtained in a straightforward manner from geomagnetic co-ordinates. The two points would be on the same parallel of geomagnetic longitude and equidistant from, and on opposite sides of, the geomagnetic equator. However, it is well known from cosmic ray observations that the dipole representation is inadequate when considering the motion of charged particles in the Earth's field. Kellogg *et al.* have therefore calculated the expected position of the aurora on the assumption that the two conjugate points will be symmetrical about the so-called cosmic ray equator.

The behaviour of cosmic rays observed at the surface of the Earth is, however, determined by the geomagnetic field configuration all the way from the surface of the Earth to distances where the field ceases to be effective. The magnetic field lines connecting Johnston Island to Samoa, on the other hand, always lie within about 350 miles of the Earth's surface and consequently we should expect a co-ordinate system based on the surface magnetic field parameters to be more appropriate than one dependent on cosmic-ray observations. We have therefore calculated the position of the conjugate point on the assumption that it should have a magnetic inclination of the same magnitude but opposite in sign to that of Johnston Island and that it should lie on the same magnetic meridian, defined by the direction of the horizontal component of the surface field. This point is marked *A* in Fig. 1, which also shows the two lines of bearing between which the aurora was observed. The distance of the display from Apia is not known since the height of the display is uncertain. The elevation, however, is known to have been 12° and the two thick lines *O* and *O′* correspond to the position of the display assuming that the aurora occurred at a height of 50 miles and 100 miles respectively. The predicted point would correspond to a height of about 70 miles, which is the most frequent height of occurrence of genuine auroral displays at high latitudes.

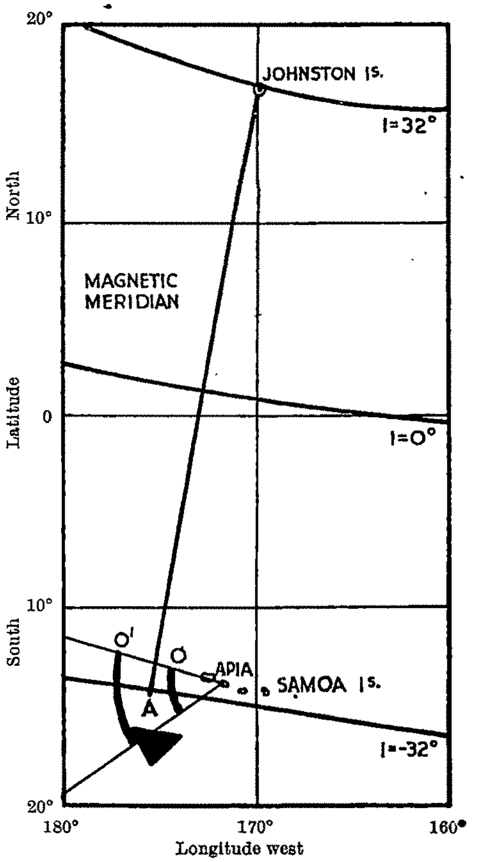

Fig. 1. *A* is the position at which the aurora would be expected. *O* and *O′* are observed positions corresponding to a height of 50 and 100 miles. Black triangle is position of aurora calculated by Kellogg *et al.*

The use of surface-field parameters clearly gives good agreement between the observed and calculated position of the aurora in this case. For high-latitude explosions, however, the guiding lines of force go out to great distances from the Earth and the surface-field values are no longer appropriate. In calculating conjugate points for high-latitude events it is necessary instead to use the co-ordinate system adopted by Quenby and Webber[4] to account for cosmic-ray phenomena.

New Bands and Lines in the Twilight Sky Spectrum

AT the Abastumani Astrophysical Observatory we have been making continuous observations of the twilight sky for seventeen years, with the view of studying the features of the Earth's atmosphere[1]. In 1957, we began to study the twilight sky spectra by means of a grating spectrograph (grating 135 × 90 mm.^2, 1,200 lines/mm. ; camera, $f = 70$ mm., dispersion 80 A./mm. in the red region). During the year beginning December 1957, 67 spectrograms were obtained in the region 5400–6800 A., of which 29 belong to the morning and 38 to the evening twilight. The well-known lines of oxygen, λλ6300–6364 A. [O I], 5577 A. [O I] and the sodium D-lines 5890–5896 A., are always present on these spectrograms. In addition, some new lines and bands appear permanently or episodically on them. Two such spectrograms are reproduced in Fig. 1. Table 1 contains the wave-lengths of the lines and bands ($\lambda_{\text{obs.}}$), the number of cases of their appearance (n) and the suggested interpretation. This is a preliminary interpretation in so far as in some cases the difference $\Delta\lambda = \lambda_{\text{obs.}} - \lambda$ (λ is an accurate value of the line or band wave-length for a given atom or molecule) reaches the value of 4–5 A., which exceeds the probable error of measurement of $\lambda_{\text{obs.}}$ (1–2 A.). Some additional systematic errors in the determination of $\lambda_{\text{obs.}}$ may have occurred. They may be caused by the high intensity and the complicated structure of the continuous spectrum of the twilight sky, on the background of which one has to study faint lines and bands.

Table 1

6491	2	Ca			6493·1						

There are some bands of molecules of N_2 and OH in Table 1. N_2 is presented by the bands of the first positive system (mainly with the sequence $\Delta v = 3$). Further, we have found two bands of a system which we believe was not hitherto known. These bands were identified recently by Le Blanc, Tanaka and Jursa[2] in a laboratory.

The line $\lambda_{\text{obs.}} = 6707 \cdot 1 \pm 0 \cdot 5$ observed by us probably corresponds to the line $\lambda_{\text{obs.}} = 6708 \pm 1 \cdot 5$ discovered by Delannoy and Weill[3,4] in the twilight spectrum. These authors identify this emission with the resonance line of Li (6707·86 A.). We regard this interpretation as probable, but apparently on our spectrograms the line fuses with the band $N_2 = 6704 \cdot 8$ A.

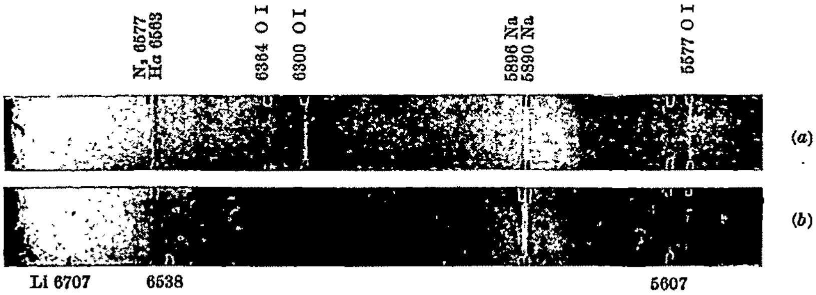

Fig. 1. (a) Augus 22, 1958. [Z = 97° 33′–101° 46′. (b) November 11, 1958. Z = 98°–101° 30′

Our observations are continuing. We intend to publish a fuller account of the observations and particularly to provide information on the height of the layers in which the glow mainly arises.

Density of the Upper Atmosphere

AN important part of the International Geophysical Year Satellite Programme is the use of satellite orbital data for the deduction of atmospheric densities at very high altitudes. Several reports on preliminary results obtained by this method have recently appeared[1,2].

Some years ago, I undertook an analysis of the density of the atmosphere to extreme altitudes[3] for use in connexion with certain theoretical studies of extreme-altitude aerodyna-

Table 1. DENSITY OF THE UPPER ATMOSPHERE (REF. 3)

Altitude (km.)	Model I Density (gm./cm.^{3})	Model II Density (gm./cm.^{3})	Model III Density (gm./cm.^{3})
	Latitude 45°		
200	$5\cdot09 \times 10^{-12}$	$5\cdot09 \times 10^{-12}$	$5\cdot09 \times 10^{-12}$
300	$1\cdot29 \times 10^{-13}$	$1\cdot29 \times 10^{-13}$	$1\cdot29 \times 10^{-13}$
400	$1\cdot16 \times 10^{-14}$	$1\cdot22 \times 10^{-14}$	$1\cdot12 \times 10^{-14}$
500	$1\cdot87 \times 10^{-15}$	$1\cdot95 \times 10^{-15}$	$3\cdot69 \times 10^{-15}$
600	$4\cdot16 \times 10^{-16}$	$3\cdot75 \times 10^{-16}$	$1\cdot54 \times 10^{-15}$
700	$1\cdot10 \times 10^{-16}$	$1\cdot32 \times 10^{-16}$	$8\cdot00. \times 10^{-16}$
1,000	$5\cdot64 \times 10^{-18}$	$4\cdot55 \times 10^{-18}$	$1\cdot65 \times 10^{-16}$
Limit of atmosphere	$2\cdot34 \times 10^{-23}$ (at 8,890 km.)	$2\cdot35 \times 10^{-36}$ (at 8,851 km.)	$2\cdot94 \times 10^{-23}$ (at 70,000 km.)
	Latitude 0°		
200	$4\cdot96 \times 10^{-12}$	$4\cdot96 \times 10^{-12}$	$4\cdot96 \times 10^{-12}$
300	$2\cdot50 \times 10^{-13}$	$2\cdot50 \times 10^{-13}$	$2\cdot50 \times 10^{-13}$

220	$4\cdot0 \times 10^{-13}$	—	$18\cdot6 \times 10^{-13}$	$25\cdot9 \times 10^{-13}$	$18\cdot6 \times 10^{-13}$	$25\cdot9 \times 10^{-13}$	$18\cdot6 \times 10^{-13}$	$25\cdot9 \times 10^{-13}$
368	$1\cdot4 \times 10^{-14}$	—	$2\cdot6 \times 10^{-14}$	$5\cdot9 \times 10^{-14}$	$1\cdot6 \times 10^{-14}$	$5\cdot9 \times 10^{-14}$	$2\cdot3 \times 10^{-14}$	$5\cdot9 \times 10^{-14}$
405	—	$9\cdot0 \times 10^{-15}$	$11\cdot6 \times 10^{-15}$	$31\cdot4 \times 10^{-15}$	$11\cdot6 \times 10^{-15}$	$31\cdot9 \times 10^{-15}$	$10\cdot6 \times 10^{-15}$	$30\cdot7 \times 10^{-15}$
720	—	$1\cdot2 \times 10^{-16}$	$0\cdot9 \times 10^{-16}$	$6\cdot5 \times 10^{-16}$	$0\cdot9 \times 10^{-16}$	$6\cdot6 \times 10^{-16}$	$7\cdot2 \times 10^{-16}$	$13\cdot1 \times 10^{-16}$
1,000	—	—	$5\cdot6 \times 10^{-18}$	$5\cdot5 \times 10^{-17}$	$4\cdot6 \times 10^{-18}$	$6\cdot1 \times 10^{-17}$	$1\cdot6 \times 10^{-16}$	$2\cdot9 \times 10^{-16}$

mics. The analysis provided density values extending to the outer limit of the atmosphere. The density values at selected altitudes from ref. 3 are shown in Table 1. These are compared in Table 2 with the recently inferred values.

The recent values are derived by somewhat indirect methods and are subject to certain errors previously discussed[1,2]. However, they do have the important advantage of being derived from observational data; whereas the values from ref. 3 especially for altitudes above 300–400 km. are based to a large extent on conceptual models. It is not clear what latitude should be used for purposes of comparison, or whether the average of the values at latitude 45° and latitude 0° would be most appropriate. Or possibly the values for latitude 45° may be accepted as representative of the average value around the Earth (that is, the average from latitude 0° to latitude 90°). Regardless of these uncertainties, it is seen from Table 2 that the recently inferred values generally fall within the range of values given in ref. 3. In fact the agreement is quite close above 300 km. if the values for latitude 45° are used. It is worth noting that the relatively high values of upper atmosphere densities predicted in ref. 3 appear to be verified by the recently deduced values.

Propagation of Finite Elastic Waves in Rubber

THE propagation of finite waves in fluids or solids generally presents considerable difficulty, both theoretically and experimentally. In rubber-like materials, however, the experimental difficulties are greatly reduced; for example, a finite pulse of unloading may be propagated simply by stretching a rubber strip and letting go of one end. A theory of this 'free retraction' has been given by James and Guth[1] and tested experimentally by Mrowca, Dart and Guth[2]. The retraction process is considered as the propagation of a stress pulse from the released tip to the fixed end, the tip itself retracting with such a velocity that the specimen achieves its unstrained state at the instant that the pulse reaches the fixed end.

High-speed cinematographic pictures (at about 2,500 frames/sec.) have confirmed this mechanism qualitatively for natural rubber. Thus in the typical frame in Fig. 1, showing a specimen in the course of retraction from an extension of 300 per cent, the narrow portion of the rubber is stationary and still at the original extension while the wide portion is substantially relaxed and moving with a constant velocity. Quantitatively, however, the theory predicted a velocity $(E/\rho)^{1/2}$ for the pulse based on the wave equation for infinitesimal strains:

$$\rho \frac{\partial^2 u}{\partial t^2} = E \frac{\partial^2 u}{\partial x^2}$$

where ρ is the density, while u is displacement and E Young's modulus, both referred to the unstrained state.

These velocities did not agree with observation, particularly for the more highly strained specimens. Mrowca, Dart and Guth found better agreement by taking the modulus from the slope of the stress strain curve at the extension used. This is formally equivalent to Taylor's treatment[3] for the velocity of plastic waves.

A different way of looking at the problem is to consider the unloading with respect to the stretched

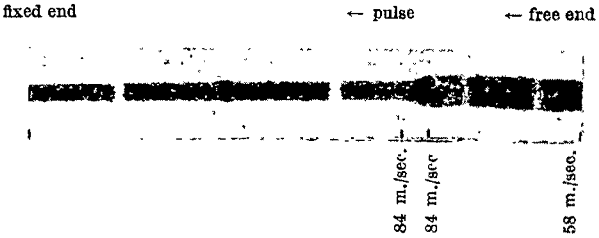

Fig. 1. Retraction of natural rubber from 300 per cent extension

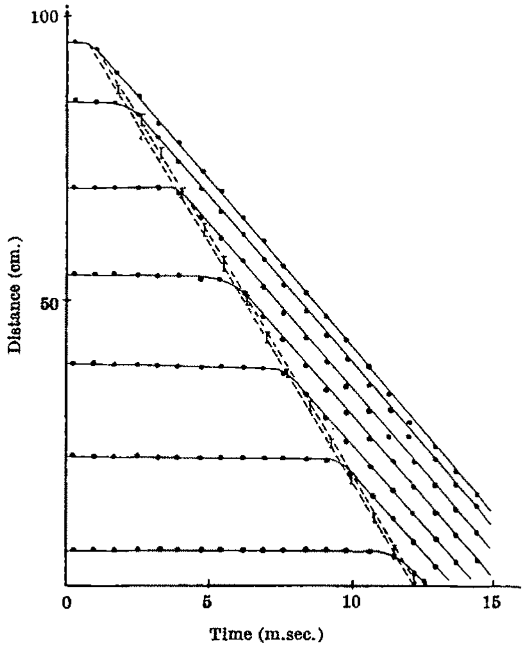

Fig. 2. Analysis of the retraction process. —●—, Reference mar on specimen ; - - -I- - -, unloading pulse

material. It could then be anticipated that, provided the wave-front were not too steep, the head of the pulse would be propagated with the velocity of longitudinal waves of infinitesimal amplitude, $\lambda[(\partial\sigma/\partial\lambda)/\rho]^{1/2}$, σ being the nominal stress and λ the extension ratio. For natural rubber at room temperature there would be little frequency dispersion, but amplitude dispersion would be expected to widen the pulse progressively because of the decrease in velocity as the material relaxes in its passage through the pulse. This is the converse of shock waves in normal solids[4].

Detailed analysis of the film records has been made to check this point, the results for natural rubber retracting from 300 per cent extension being shown in Fig. 2. The passage of the unloading pulse is clearly defined, and it is apparent that there is very little dispersion. The pulse velocity here is 84 m./sec. and the pulse-width approximately 1·5 cm. (0·2 msec. in time) throughout.

Direct measurements of the infinitesimal longitudinal wave-velocity in stretched rubber filaments have already been obtained in another context[5], and Table 1 shows the relation between these values and the velocities of finite pulses observed in retraction for natural and butyl rubbers.

Table 1. Velocities of Finite and Infinitesimal Waves in Stretched Rubber

Rubber	Extension (per cent)	Finite pulse velocity (m./sec.)	Infinitesimal wave velocity at 40° C. (1 kc./s. m./sec.)
Natural	18	46	40
,,	72	45	42
,,	100	57	44
,,	190	62	58
,,	295	84	84
Butyl	42	66	70
,,	122	57	71
,,	209	73	73
,,	328	82	70–84
,,	425	95	97

It thus appears that the velocity of the head of the pulse is substantially the same as that of the infinitesimal waves, but the absence of dispersion is a paradox.

This work forms part of the research programme of the Board of the British Rubber Producers' Research Association.

ENGINEERING

Grinding at Super-Critical Speeds in 'Ball' Mills

In recent years the possibility of grinding materials in machines of the 'ball-mill' type, when running at speeds greater than the critical, has received some attention, and a number of machines operating under these conditions are in industrial use.

The rather limited literature relating to the subject appears, in general, to support the view that the major part of the grinding process arises from the sliding which occurs between the mill shell and the charge, and is localized in this region.

It would appear to be questionable, however, whether such localized action would produce a grinding effect comparable in magnitude with that obtained under sub-critical speed conditions, when grinding occurs between the greater part of the grinding elements in the charge, whereas a grinding effect of this order of magnitude appears to be obtained in practice.

In view of this question the following observations, made upon a small-scale model mill running at 1½ times the critical speed and fitted with a transparent end cover, appear to be relevant and to throw some light upon the nature of the grinding process which occurs under these conditions.

When running at above the critical speed, the charge in the mill oscillates within the mill shell in a pendulum-like manner ; the oscillation being such that, as in Fig. 1*a*, the leading edge of the charge ascends to an altitude of about 45° above the horizontal, at about which position, owing to deceleration

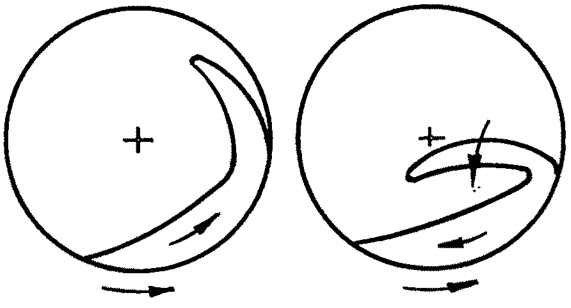

Fig. 1

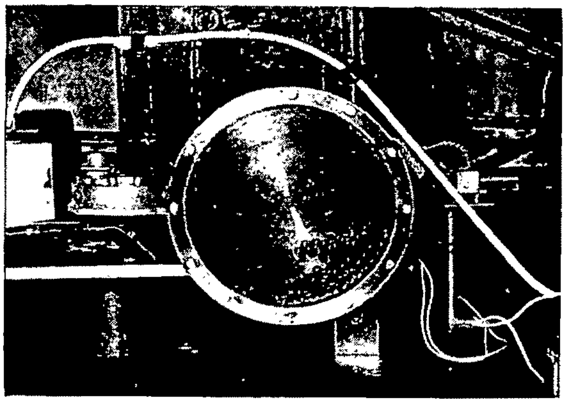

Fig. 2

of the charge due to slip at the mill shell, the leading part of the charge collapses and, as in Fig. 1*b*, falls as a coherent mass upon the lower portion of the charge.

This falling mass of charge is shown clearly in the photograph, Fig. 2.

This falling mass of charge gives rise to a heavy blow, and, in the case of a mill with an autogenous charge, or one in which the powder is in excess of that required to fill the void space between the grinding bodies, this blow could produce a grinding effect which could well be in excess of that arising from the sliding between the charge and the mill shell.

It is also of interest to notice that the descending charge falls upon the remainder of the charge and is not projected upon the mill wall. Thus the condition in which the charge impinges upon the mill liners, a condition which gives rise to excessive liner wear, does not arise.

It has also been observed that, under certain conditions, the slip occurs not at the mill shell but between the charge and the first layer of balls. It is possible that, if this condition could be maintained in practice, wear of the mill liners could, even with super-critical speed milling, be reduced to a magnitude comparable with that encountered in sub-critical speed milling.

METEOROLOGY

Poisson's Law and the Frequency of Hurricanes

Poisson's law, or the 'law of small probabilities' as it is sometimes called, is used at times for describing the probabilities that no, one, two, etc., particular events of a relatively infrequent character will occur in a single year. It has been used in the estimation of the probability of one or more hurricanes striking a given area, say, New England, in a year. The purpose of this communication is to point out weaknesses inherent in this treatment, and to suggest one or more alternative approaches.

In the development of Poisson's law, it is assumed that the occurrence of a single event of the specified sort neither increases nor decreases the probability of occurrences of another event of the same sort. Thus in the use of Poisson's law in the estimation of the probabilities of hurricanes, it is tacitly assumed that the arrival of a single hurricane in the specified region neither increases nor decreases the probability that another hurricane will strike the region in the near future. In other words, hurricanes striking a given area are considered as entirely independent events. This would imply that such a thing as a trend or regular pattern does not exist.

There are two types of arguments which could be used for supporting the idea of a trend in hurricanes. In one, it is argued that once a hurricane has passed through a region, the energy available to feed a hurricane has been diminished, and there is less chance of a hurricane striking the area than previously.

In the other thesis, one would argue that the arrival of one hurricane demonstrates that conditions are favourable for such an occurrence, and that therefore the probability of the arrival of another hurricane in the area is greater than previously. The latter argument appears likely to have the greater appeal to those meteorologists supporting the idea of a trend.

As a particular case, consider the Caribbean hurricanes striking New England, which is here taken as that part of the United States east of the Hudson River and north of Long Island Sound. Observational data, which are not necessarily complete or entirely accurate, indicate that twelve hurricanes have moved into this area in 320 years (up to 1953). This can be used as the basis of a Poisson distribution:

$$1 = e^{-z}(1 + z + z^2/2 + z^3/6 + \ldots \text{etc.})$$

where the successive terms on the right represent the probabilities of no, one, two, etc., hurricanes striking in a single year. Thus for Caribbean hurricanes striking New England:

$$ze^{-z} = 3/80 = 0{\cdot}0375$$

which gives $z = 0{\cdot}039$ and $e^{-z} = 0{\cdot}96175$. Hence, according to Poisson's law, the probabilities of no, one, two, three hurricanes in New England in a single year are 0·96175, 0·03750, 0·00073, 0·00001 respectively. This would imply that New England will, on the average, have a year with two hurricanes about every 1,370 years, a year with three hurricanes once in a hundred thousand years. The year 1954 provided the area with enough two-hurricane years for more than a thousand years and came near to supplying a three-hurricane year. ('Hazel' 1954 passed somewhat to the west of the Hudson River.) Yet another hurricane flooded New England the following year.

Looking again at Poisson's law, it is seen that it says two things: (1) that the sum of the probabilities is one which means that there will certainly be no hurricane or one hurricane or two hurricanes, etc., in a year; (2) that the ratio between consecutive terms, say, between the $(n + 1)$st and the nth is z/n, or in other words, the ratio of the probability of n hurricanes in a year to the probability of $(n - 1)$ hurricanes in a year is only slightly greater than $1/n$ of the probability of one hurricane in a year.

This last statement gives a clue to a possible approach to the problem of deciding whether a trend exists. When observations have been made over a sufficiently long period to determine approximately the frequency of years with no, one, two hurricanes, the ratios of the frequencies, $F_0 : F_1 : F_2$ can be taken as approximations to the ratios of the probabilities, $P_0 : P_1 : P_2$. One can then ask: Is $2P_2/P_1$ approximately equal to P_1/P_0? If the first ratio is significantly different from the second, Poisson's law cannot be used in this problem with any confidence.

If Poisson's law is not to be used, what can be done? Clearly the sum of all the probabilities must remain 1; the only thing which can be changed is the ratio between consecutive terms. If experience shows that the consecutive terms in Poisson's law diminish too rapidly, that the law indicates fewer two-hurricane years than usually occur, the ratio of consecutive terms should be increased, perhaps from z/n to z as a first trial. The series of probabilities corresponding to this assumption is:

$$1 = V(1 + z + z^2 + \ldots + z^n + \ldots)$$

where V must be chosen so that the sum of all terms on the right is 1. But for small values of z (a standard restriction imposed in the use of Poisson's law):

$$1 + z + z^2 + z^3 + \ldots + z^n + \ldots = 1/(1 - z)$$

Hence $V = (1 - z)$ and the series becomes:

$$(1 - z)(1 + z + z^2 + \ldots + z^n + \ldots)$$

To use this with the data for New England hurricanes, $(1 - z)z = 3/80 = 0{\cdot}0375$ and $z = 0{\cdot}0390$. The corresponding sequence of probabilities is 0·96098, 0·03750, 0·00146, 0·00006. According to this, the probabilities of two-hurricane years and three-hurricane years are approximately double and six times the corresponding probabilities as estimated by Poisson's law.

But even this may not match the actual frequency of two-hurricane and three-hurricane years. To increase the ratios between consecutive terms even more, one may try:

$$1 = W(1 + z + 2z^3 + 3z^3 + \ldots + nz^n + \ldots)$$

Then $W = (1 - z)^2/(1 - z + z^2)$ and the sequence becomes:

$$1 = \frac{(1-z)^2}{1-z+z^2}(1 + z + 2z^2 + 3z^3 + \ldots + nz^n + \ldots)$$

Applying this to the above data for New England hurricanes:

$$\frac{z(1 - z)^2}{1 - z + z^3} = 0{\cdot}0375 \text{ and } z = 0{\cdot}039095$$

and the sequence of probabilities is 0·95920, 0·03750 0·00293, 0·00034. This sequence provides probabilities of two- and three-hurricane years four and thirty-six times those given by Poisson's law. Recalling that New England has had one year with two hurricanes in about 325 years, the probability of a two-hurricane year can, on the basis of past experience, be taken as about 0·003. This is equal to the largest value of the corresponding probability of the three given above.

This suggests that with the arrival of one hurricane in New England, the probability of a second one within the year is somewhat greater than was that of a first one, say, four times as great. This may be counted as evidence that there is such a thing as a trend in hurricanes. Even the slightest evidence of regularity is encouraging, since it implies there is hope that some day, with a better understanding of hurricanes, their motions can be predicted with greater certainty.

CHEMISTRY

Potentiometric Titration of Coal in a Non-Aqueous Medium

Brooks and Maher[1] have determined the groups in a wide range of Australian coals which contain acidic oxygen by titration of a suspension in anhydrous ethylenediamine, using sodium amino-ethoxide in ethylenediamine as the titrant. They used two antimony electrodes, one in the reaction medium and the second built into the burette tip, where it was washed continuously by the titrant. The use of the basic solvent ethylenediamine permitted the titration of carboxylic acid groups and probably the more strongly acidic phenolic groupings, though Fritz and Keen[2] state that some substituted phenols are too weakly acidic to be titrated, as are some polyhydric phenols such as resorcinol and catechol, where no definite end-point can be located. However, according to van der Heijde and Dahmen[3], increased basicity of the solvent does not lead to an increased apparent acidity of weak (that is, non-levelled) acids. If there is any influence at all it works in the opposite direction.

In the present work *n*-butylamine has been used as the solvent and sodium methoxide in benzene/methanol solution as the titrant. The apparatus was essentially that of Brooks and Maher[1], with the exception that the electrode in the burette tip was of platinum–10 per cent rhodium alloy instead of antimony. The platinum–rhodium electrode was connected to the positive terminal, and the antimony electrode in the reaction medium to the negative terminal, of a Pye 'Master' *p*H meter, both leads being screened and earthed. Under the conditions used by Brooks and Maher the addition of titrant resulted in a fall in e.m.f. and it was necessary to allow a period of at least 1 hr. after the addition of the solvent to the coal for equilibrium to be reached before the start of the titration. With *n*-butylamine, however, a maximum of 15 min. stirring was all that was necessary before a constant mV.-reading was obtained and the titration started. The platinum–rhodium versus antimony electrode combination results in an initial e.m.f. of between −400 and −500 mV., which becomes increasingly negative as the titration proceeds.

A number of British coals, ranging in rank from 201 to 902 and in carbon content from 92 to 79 per cent, have been titrated. The quantitative results are set out in Table 1 and two of the curves obtained when the volume of titrant is plotted against mV. are shown in Figs. 1 and 2. While the high-rank coals of more than 90 per cent carbon show little or no differentiation and a low content of titratable acidity, the lower-rank coals show interesting qualitative differences. The shape of the curves (though not the titre) is the same for coals of the same rank, and the differences between coals of different rank are apparently indicative of changes in structure. However, the interpretation of these titration curves is difficult since the occurrence has been reported[4] of anomalous curves due to acid–anion association and also because of the possibility that internal hydrogen bonding[5] will lead to enhanced acidity. Evidence of the existence of hydrogen-bonded phenolic hydroxyl groups in a number of coals has been put forward by Brown and Wyss[6].

The determination of the phenolic hydroxyl groups in coal has been carried out by Wyss[7] using an acetylation method. He found that the proportion of the total oxygen present as acetylatable hydroxyl groups varied between 35 and 44 per cent for coals of carbon content ranging between 77 and 89 per cent, and that above 89 per cent carbon there was a sharp drop in this proportion to 10 per cent or less. In the present work the range is wider, coal of 79–86 per cent carbon showing a proportion of 30–49 per cent of the total oxygen present as titratable acidic groups. There is some indication also that the higher proportions are localized in the range 84–86 per cent carbon in agreement with the work of Mazumdar[8]. The results for the high-rank coals (Nos. 1–6) are higher than those obtained by Wyss ; but the accuracy is doubtful because of the low titres involved and the consequent enhanced effect of the blank correction.

Electrolytic Deposition of Beryllium

Beryllium is of interest in the atomic energy field because of its low absorption and high scattering cross-section for thermal neutrons. The metallurgical properties and nuclear applications of the metal have been reviewed recently[1]. The electrolytic deposition of beryllium from solutions of beryllium compounds in organic solvents[2] and in liquid ammonia[3] has been studied. In the most recent work[4], published immediately before completion of the present investigation, coherent deposits of beryllium of up to 95 per cent purity were obtained during the electrolysis of a solution containing dimethyl beryllium and beryllium chloride etherate in ethyl ether. Deposits obtained from this bath were superior to the powdery deposits obtained by electrolysis of a 2·8 *M* solution of $BeCl_2.2(C_2H_5)_2O$ in ethyl ether. Although one of the commercial methods of manufacturing beryllium involves the high-temperature electrolysis of beryllium chloride[5], in alkali halide melts the possibility of recovery and electro-refining of scrap metal by anodic dissolution and cathodic deposition has received little attention.

In the present work a number of non-aqueous systems have been examined with the view of finding a system from which coherent coatings of high-purity beryllium could be obtained on electrolysis. The anodic dissolution and cathodic deposition of beryllium in molten salt baths has also been studied[6].

All organic solvents were dried for long periods over an appropriate desiccant and distilled before use. Gaseous ammonia was condensed over sodium before distillation into the electrolysis cell. Commercial grade beryllium chloride was purified by reaction

Table 1. ELECTROLYSES IN SOLUTIONS CONTAINING BERYLLIUM CHLORIDE AT 20° C.

Solvent	Cathodic current density (amp. dm.$^{-2}$)	Deposits obtained on electrolysis
Liquid ammonia (−33° C.)	1·0–5·0	Black reactive deposits
Piperidine	0·015	Grey metallic streaks containing beryllium
Pyrrole	0·015–2·0	Grey metallic streaks containing beryllium
Aniline	0·15	Black tarry deposit
Ethylenediamine	1·0	Black non-metallic deposit
Ethylenediamine + NH_4CNS	1·0	Black non-metallic film
Methyl cyanide	1·0	Gassing at electrodes—no deposit

Table 2. ELECTROLYSES IN ETHEREAL SOLUTIONS OF BERYLLIUM CHLORIDE AND BERYLLIUM DIMETHYL AT 20° C.

Solution	Cathodic current density (amp. dm.$^{-2}$)	Deposit obtained on electrolysis
5 per cent w/v $Be(CH_3)_2$	0·15	Smooth, brittle, black metallic deposit
5 per cent w/v $Be(CH_3)_2$ with added $BeCl_2$	1·0–2·5	Black, flaky, metallic deposit containing 30 per cent beryllium
5 per cent w/v $BeCl_2$	0·2	Shiny, black metallic film
2·5 *M* $BeCl_2.2(C_2H_5)_2O$	1·0	Metallic flashes of beryllium

with hydrogen at 300° C. to reduce ferric iron to non-volatile ferrous iron, followed by distillation. All transfer operations were carried out in an inert atmosphere in a glove box and the electrolyses were carried out in an atmosphere of pure, dry oxygen-free nitrogen or argon. Platinum or beryllium anodes and copper cathodes were used throughout.

The results are given in Tables 1 and 2. Only traces of black, non-metallic deposits were obtained in liquid ammonia solutions of beryllium chloride, in agreement with the observations of Wood and Brenner[4]. The solubility of beryllium chloride in piperidine, pyrrole, aniline and ethylenediamine was low (20–30 gm./l.). Although the grey streaks obtained on the cathode during prolonged electrolyses (several days duration) in piperidine and pyrrole were shown by spectrographic analysis to contain beryllium and appeared metallic under the microscope the results were not sufficiently encouraging to warrant extended investigation of these systems. Electrolyses carried out in solutions of beryllium dimethyl and mixtures of beryllium dimethyl and beryllium chloride in ethyl ether led to the preparation of smooth black coatings. These deposits, although lustrous when examined microscopically, were impure. The coatings obtained during the electrolyses of 2·5 *M* solutions of the compound $Be2Cl_2.2(C_2H_5)_2O$ in ethyl ether were more lustrous than those obtained above but were still impure.

By far the most promising results were obtained from the beryllium chloride etherate bath at 150° C. Prolonged electrolysis (7 days) was necessary before bright, thin films of metallic beryllium were obtained. Initially, gassing occurred at the electrodes followed by the appearance of powdery deposits and finally coherent films. Spectrographic analyses indicated that only beryllium was present in these coatings. The impurities iron, nickel and aluminium normally associated with beryllium were found to be absent.

The anodic dissolution of beryllium in molten eutectic mixtures of lithium and potassium chlorides and sodium and beryllium chlorides at 400° C. was also investigated. Beryllium dissolved anodically in these baths with high current efficiency at current densities up to 50 amp. dm.$^{-2}$. High-purity beryllium in the form of flakes was recovered at the cathode. Growth lines similar to those observed on electrolytic titanium deposited from fused chloride systems[7] have been observed on the flake metal.

We wish to thank Dr. J. Sackman for the preparation of samples of beryllium dimethyl for electrolysis and the United Kingdom Atomic Energy Authority for permission to publish this work.

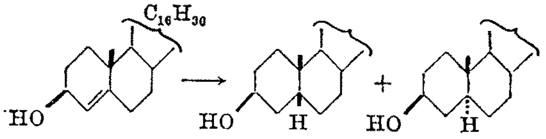
Effect of Alkali Salts on the Steric Course of Hydrogenation of a Cyclic Allylic Alcohol

INSPECTION of the literature reveals that hydrogenation of many, but not all, cyclic allylic alcohols gives products in which at least one hydrogen has been added to the same side of the molecule as the hydroxyl group. Thus, Schoenheimer and Evans[1] reported that hydrogenation of allocholesterol (I) in amyl ether solution in the presence of a platinum catalyst gave coprostanol (in unstated yield). A re-investigation of this reaction was undertaken in an attempt to determine more precisely the influence of hydroxyl or other neighbouring groups on the stereochemistry of hydrogen addition.



(I) (II) (III)

It was found that cholestanol (III) and a hydrocarbon fraction were always obtained along with coprostanol (II) when allocholesterol was hydrogenated in ethanol solution in the presence of an Adams platinum catalyst. Further work showed

Table 1

Catalyst		Yields (per cent)		
		II	III	Hydrocarbon
A_1	Adams catalyst	67	25	5
A_2	Adams catalyst	70	24	6
B_1	Catalyst A_1 pre-reduced and thoroughly washed with water	10	15	74
B_2	Catalyst A_2 similarly treated	19	22	59
C_1	Catalyst B_1 + $NaNO_3$ (1 per cent of catalyst weight), in solution	57–64	30–36	0–9
C_2	Catalyst B_2 + $NaNO_3$ (1 per cent)	66	27	7

Catalysts A_1 and A_2 were made by heating chloroplatinic acid and 'Analar' sodium nitrate in the respective weight ratios 1 : 20 and 1 : 50 at 420° C. for 1 hr., followed by washing with distilled water until sodium nitrate had been removed.

that the small amounts of sodium salts normally present in Adams catalyst[2–4] greatly affected the course of the reaction.

The highest yields of coprostanol were obtained by hydrogenation of allocholesterol in the presence of catalysts prepared *in situ* from the hydrated dioxide obtained from the fusion process (cf. catalysts *A*). When sodium salts were removed by pre-reduction of the dioxide and washing, the yields of hydrocarbon (hydrogenolysis products) were increased largely at the expense of coprostanol (cf. catalysts *B*). The properties of the original catalysts *A* could apparently be reconstituted by the addition of small amounts of various sodium salts (cf. catalysts *C*).

It will clearly be advisable in future work on the stereochemistry of olefin hydrogenation promoted by platinum catalysts to determine the effect of alkali salts, present extraneously or added deliberately.

Cohesive Energy Density of Polystyrene

Bristow and Watson[1] have recently described the determination of the cohesive energy densities of polymers by swelling and viscosity measurements. This communication summarizes the results of viscosity measurements on polystyrene solutions directed towards a similar end. The measurements cover a slightly different range of solvents from that of Bristow and Watson, and in some solvents a range of molecular weights has been investigated.

Values of the polymer–solvent interaction constant μ are obtained using the Flory–Fox[2] equations :

$$\alpha^5 - \alpha^3 = C'(1 - 2\mu + x^{-1/2})M^{1/2}/V_1$$

$$\alpha^3 = [\eta]/[\eta]_\theta$$

where x is the chain-length of the polymer, V_1 is the molar volume of the solvent, and $[\eta]$ and $[\eta]_\theta$ are the experimentally determined intrinsic viscosities in the solvent and 'ideal' solvent, respectively. Values of μ obtained in this way (at 25° C.), and taking[3] $C' = 3{\cdot}0$, for a polystyrene ($\overline{M}w$ = 300,000) are given in Table 1. That these results are slightly higher than those of Bristow and Watson is in part attributable to their use of an $\overline{M}n$ value. Also listed are some values obtained from swelling measurements[3] from another set of viscosity measurements[3], from osmotically determined second virial coefficients[4] and from vapour-pressure measurements[5]. The agreement is reasonably satisfactory. The viscosity method should yield lower values than either swellings or vapour pressures, and this is borne out, particularly in the case of the solvents butanone and *n*-propyl acetate. It is noteworthy that the results reveal the expected[6] decrease of V_1 with increase of α, though the points scatter appreciably.

Table 1

Solvent	This work		μ (Ref. 1)	μ (*a*)	μ (*b*)	μ (*c*)	μ (*d*)
	$[\eta]$	μ					
Chloroform	1·070	0·459	0·429	0·43	0·452	—	—
Benzene	1·020	0·460	0·438	0·45	0·435	—	—
Tetrahydrofuran	1·020	0·460	—	—	—	—	—
Toluene	0·990	0·453	0·432	0·44	0·438	0·434	0·44
Dioxane	0·920	0·476	—	—	0·466	0·472	—
Nitrobenzene	0·721	0·493	—	—	—	—	—
n-Propyl acetate	0·557	0·507	—	—	—	—	0·64
Butanone	0·546	0·511	0·506	0·53	0·506	0·485	0·66
'Ideal'	0·405	(0·519)	—	—	—	—	—

(*a*) From swelling measurements (ref. 3).

(*b*) From viscosity measurements; $[\eta]_\theta$ calculated from $[\eta]_\theta = 7{\cdot}3 \times 10^{-4} M^{1/2}$; $\overline{M}w$ = 370,000.

(*c*) From osmotic second virial coefficient; $\overline{M}w$ = 750,000.

(*d*) From vapour pressure measurements (ref. 5).

The dependence of μ on molecular weight was investigated at 25° C. in three solvents, and typical results are given in Table 2, together with some values derived from other work[7]. All reveal the same trend, namely, increase of μ with decrease of molecular weight. A similar but rather small trend is shown by the values calculated from osmotic second virial coefficients, using the simple Huggins's expression and provided the term $x^{-1/2}$ is taken into account (0·472, 0·481 and 0·484, respectively, in toluene).

The cohesive energy densities are related, according to Huggins[8], by the equations:

$$\mu = \beta + V_1(\delta_1 - \delta_2)^2/RT$$

where δ_1 and δ_2 are the values for solvent and polymer, respectively, and β is a further parameter. A plot of

Table 2

$\overline{M}w \times 10^{-3}$	1,040		625		169		1,500*	290*	72*
Solvent	$[\eta]$	μ	$[\eta]$	μ	$[\eta]$	μ	μ	μ	μ
Benzene	2·80	0·436	1·83	0·445	0·587	0·485	0·437	0·438	0·474
Toluene	2·45	0·440	1·67	0·450	0·560	0·483	0·429	0·448	0·472
Butanone	1·29	0·500	0·918	0·502	0·355	0·521	0·496	0·508	0·527
'Ideal'	0·778	(0·510)	0·585	(0·513)	0·301	(0·525)	(0·508)	(0·519)	(0·538)

* $\overline{M}n$ by osmometry ; $[\eta]_\theta$ calculated from $[\eta]_\theta = 7{\cdot}3 \times 10^{-4} M^{1/2}$.

$(\delta_1^2/RT) - (\mu/V_1)$ against δ_1 gave $\delta_2 = 8{\cdot}73$ (cal./cm.$^3)^{1/2}$ from the present measurements on $\bar{M}w$ = 300,000. (The results in Table 2 reveal no dependence of δ_2 on molecular weight but measurements in a wider range of solvents are needed for this point to be substantiated.) Bristow and Watson found $\delta_2 = 8{\cdot}56$ (cal./cm.$^3)^{1/2}$. Both sets of measurements combined cover a range of δ_1 from 7·82 to 10·4 (cal./cm.$^3)^{1/2}$, but the highest and lowest points deviate somewhat from the line. Omitting these we find $\delta_2 = 8{\cdot}76$ (cal./cm.$^3)^{1/2}$ and $\beta \sim 0{\cdot}4$. Viscosity measurements interpreted in this way thus lead to a value of 75 ± 2 cal./cm.^{3} for the cohesive energy density of polystyrene.

I thank Mr. J. S. Powell for some of the measurements. This work is published by permission of the Director of the National Chemical Laboratory.

Biosynthesis of Rubber

Bandurski and Teas[1] have shown that rubber in *Hevea brasiliensis* has its origin in acetate, although Park and Bonner[2] have been unable to repeat these observations, and could not show the incorporation of β-hydroxy-β-methylglutarate or of β-methylcrotonate into rubber. The acetate pathway, with its analogies in fatty acid and sterol biosyntheses, remains very attractive. Mevalonate has been incorporated into rubber[2]; but Barlow and Patrick[3] were unable to show its incorporation after application to *Hevea* leaves and stems. Much of the acetate administered to *Hevea* seedlings is directed towards respiratory metabolism[4]. The results of our experiments on incorporation of acetate and mevalonate cast some doubt on the validity of the conclusions of Bandurski and Teas.

Hevea brasiliensis latex, freshly tapped from 7-year-old trees growing under glass in Birmingham, was incubated at 28–35° with sodium-1-^{14}C-acetate, sodium-2-^{14}C-acetate and 2-^{14}C-mevalonic lactone, with and without the co-factors used by Bandurski and Teas[1]. The latex used was shown to be a good source of co-enzyme *A* [5]. After investigation of several different extraction procedures, the rubber was obtained finally as a poly-(dibromo-*iso*prene) prepared by the method of Gowans and Clark[6]. The reproducibility of this method was checked by the infra-red spectrum of the micro-crystalline bromo-compound, which showed a strong absorption peak at 775 cm.$^{-1}$, probably associated with the C—Br linkage[7]. Counting methods used comprised both gas-phase counting of carbon dioxide labelled with carbon-14 obtained by dry combustion in oxygen and solid counting on aluminium disks. Typical results, using sodium-1-^{14}C-acetate, are shown in Table 1. It should be pointed out that even at the highest value obtained by Bandurski and Teas only $10{\cdot}7 \times 10^{-4}$ μmole of acetate had been incorporated into rubber in 8 hr. We have been unable to observe the incorporation *in vitro* of mevalonate into rubber with the aid of fresh latex.

Table 1. INCORPORATION OF ACETATE INTO RUBBER

Mixture incubated	Poly-(dibromo-*iso*prene) c.p.m./mgm. rubber carbon
Acetate + 0·1 ml. latex without co-factors	9
Acetate + 1·0 ml. latex without co-factors	23
Acetate + 1·5 ml. latex with co-factors + sucrose	0
Bandurski and Teas (ref. 1) results :	
Acetate + 0·1 ml. latex without co-factors	26
Acetate + 0·1 ml. latex with co-factors + sucrose	297

A search was made for other possible biosynthetic intermediates, notably β-hydroxy-β-methylglutaric acid and β-methylcrotonic acid, formed during the metabolism of sodium-1-^{14}C- and -2-^{14}C-acetate, by modifications of the method of Rabinowitz and Gurin[8]. After halting the reactions by the addition of metaphosphoric acid, carrier compounds were added to the incubated mixtures of latex and acetate. Crystalline compounds were isolated, purified by repeated recrystallizations and paper chromatography. Paper autoradiography of the isolates failed to reveal any radioactivity associated with β-hydroxy-β-methylglutaric or β-methylcrotonic acids. Similarly, after incubation of latex with labelled mevalonate, no evidence could be obtained for the formation of possible breakdown products (β-hydroxy-β-methylglutaric or β-methylcrotonic acids), as suggested by reactions catalysed with flax enzymes[9]; it appeared that most of the mevalonate remained unchanged.

It is realized that the *Hevea* trees used in this investigation did not approach in size or latex yield the trees used by Bandurski and Teas, but it must be stressed that the role of both acetate and mevalonate as rubber precursors is by no means established. Until an overall carbon balance for the fate of these precursors when added to isolated enzyme and co-enzyme systems from latex has been completed, it is unlikely that a definitive assessment of the results of radioactive experiments can be made.

We acknowledge the constant advice and interest of Prof. M. Stacey, and thank Dr. R. H. Cornforth for a sample of 2-^{14}C-mevalonic lactone, Dr. J. C. Bevington for help with radioactive measurements and the Dunlop Rubber Co., Ltd., for the award of a scholarship to one of us (P. J.).

BIOCHEMISTRY

Feulgen–Naphthoic Acid Hydrazide Reaction applied to Blood Smears

HÆMATOLOGICAL use of Schiff's reagent for the Feulgen reaction[1] has been described by Gardikas and Israels[2]. This technique, or minor variations of it, has been used extensively to identify the number of nucleoli in primitive normal or pathological leucocytes. There is a perinucleolar concentration of nuclear protein, but the nucleoli themselves are free of deoxyribonucleic acid.

The method has one disadvantage in that deep staining cannot be obtained and smears must usually be examined for the specific red coloration with the aid of a green sub-stage filter. The purpose of this communication is to direct attention to the naphthoic acid hydrazide reaction described by Pearse[3,4]. A modification of Pearse's method has been found to give excellent results with smears of blood or bone marrow from a number of species (man, horse and dog). The intensity of staining available with fast blue *B* is considerably greater than that available with Schiff's reagent. The method is as follows.

Fresh, air-dried smears are fixed for 30 sec. on the staining bridge with a solution consisting of 10 ml. of 40 per cent formaldehyde and 90 ml. of absolute methanol kept in the refrigerator at 0° C. The smears are rinsed in distilled water and then in *N* hydrochloric acid. Hydrolysis is performed at 60° C. for 10 min. in *N* hydrochloric acid. After this the smears are again rinsed in *N* hydrochloric acid, in distilled water, and in 50 per cent ethyl alcohol. They are incubated for 5 hr. in naphthoic acid hydrazide at 20–22° C. made up as follows: 0·1 gm. 2-hydroxy-3-naphthoic acid hydrazide (L. Light and Co.) is dissolved in 50 ml. absolute ethanol. 45 ml. distilled water and 5 ml. glacial acetic acid are then added. After incubation the slides are immersed in three changes of 50 per cent ethyl alcohol for 10 min. each, rinsed in distilled water, and stained in freshly prepared fast blue *B* at 0° C. for 3 min. prepared as follows. Fast blue *B* (G. T. Gurr) 5 mgm. dissolved in 0·1 *M* veronal buffer *p*H 7·4, 5 ml. The buffer is kept in the refrigerator in small jars of 5 ml. capacity to which the fast blue *B* is added just before staining. The latter is performed in a Petri dish in the refrigerator. The slides are then washed in distilled water and blotted dry.

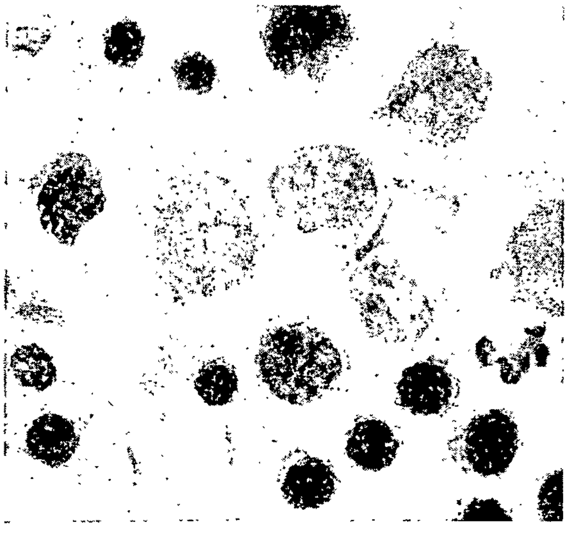

Fig. 1. The Feulgen–naphthoic acid hydrazide reaction applied to a smear of horse bone marrow. Deoxyribonucleic acid stains bluish-purple. Cytoplasm stains faint pink

Using this technique Fig. 1 illustrates a typical group of cells from a horse bone marrow specimen. Deoxyribonucleic acid stains bluish-purple while the cytoplasm of the cells stains a faint pink. The smears are easily seen microscopically without light filtration and the distribution of the bluish-purple fast blue *B* stain is identical with that of the more usual Schiff reagent in the Feulgen reaction.

Destruction of Cortisone and Related Steroids by Traces of Copper during Purification Procedures

WE wish to report the destruction of μgm. quantities of cortisone and related steroids by traces of cupric ion and the prevention of such destruction by addition of ethylenediamine tetraacetic acid.

In the course of developing paper chromatographic procedures for the purification and estimation of adrenal steroids in urine, poor recoveries of cortisone and cortisol were obtained repeatedly. In addition, the simultaneous formation of several transformation products was observed.

The cause of the destruction was traced ultimately to the glassware, which routinely had been washed in hot detergent solution ('Diflex'), rinsed with distilled water, and dried in an oven. Analysis of the distilled water revealed the presence of approximately 1 mgm. of copper/l. Two 125-ml. Erlenmeyer flasks received from the washroom on separate days contained 2·7 and 3·0 μgm. copper. Special treatment of test-tubes with sulphuric acid–dichromate, followed by repeated rinsing with copper-free water obtained from a de-ionizer, greatly reduced the loss of added steroid but did not prevent it completely. However, the prior addition of a small amount of ethylenediamine tetraacetic acid, even to tubes not especially pretreated, resulted in quantitative recoveries of added cortisone.

In a typical experiment 4 μgm. of cortisone in 10 μl. of methanol was added to each of three 'Pyrex' test-tubes, size 100 mm. × 10 mm., only the first of which had been washed in sulphuric acid–dichromate and rinsed with copper-free water. The second tube served as a control, and 50 μgm. of disodium ethylenediamine tetraacetic acid in 0·5 ml. of methanol was added to the third tube. 1 ml. of methanol was added around the sides of each tube, and then evaporated in a stream of carbon dioxide. After being allowed to stand for 3 hr. at room temperature, the residues were transferred individually with two 25-μl. portions of methanol to spots on a 7-in. sheet of unwashed Whatman No. 1 paper. Cortisone standards of 0·5–4·0 μgm. were added in spots along the same line. Chromatography was performed by Bush's[1] system *C* after an overnight equilibration. By a procedure similar to that of Neher and Wettstein[2], quantitation was done on the bases of blue tetrazolium reduction and of soda fluorescence. The recoveries from the tube washed in sulphuric acid–dichromate and rinsed with copper-free water, that washed in the routine manner, and that washed in the routine manner and treated with 50 μgm. ethylenediamine tetraacetic acid were 95, 62 and 100 per cent, respectively.

Destruction was accompanied by the appearance of three new spots on the chromatogram. One spot was at the origin, another was just below the origin, and the third spot had migrated 1·45 times as far as the cortisone. The derived substances absorbed illumination at 254 mμ and gave soda fluorescence, but in the quantities obtained they did not reduce blue tetrazolium. Artefacts were not formed in detectable amounts from the fresh cortisone standards which were transferred from the stock solutions in methanol directly to the paper. However, in stock solutions which initially contained 4 μgm./10 μl., artefacts were detectable 2 weeks after they had been prepared. But in the presence of 10 μgm. of disodium ethylenediamine tetraacetic acid per ml. of methanol, artefacts were not detectable in solutions of cortisone and cortisol 8 weeks after they had been prepared.

The effect of addition of 1 μgm. copper (as cupric chloride) on cortisone and a number of related steroids was studied. All glassware was washed with acid and rinsed with copper-free water. 10 μl. of water which contained 1 μgm. copper was poured into a test-tube and taken to dryness in a desiccator. 4 μgm. of steroid in 10 μl. of methanol was added and the sides of the test-tube were rinsed with 1 ml. of methanol. The remainder of the procedure was as described above. Recoveries of all steroids from such control test-tubes not containing added copper were essentially quantitative. The recoveries of cortisone and cortisol after addition of 1 μgm. of copper were 50 and 75 per cent, respectively ; recoveries were quantitative when both 1 μgm. copper and 50 μgm. ethylenediamine tetraacetic acid were added. 1 μgm. copper caused considerable loss of 11-dehydrocorticosterone and smaller losses of corticosterone, aldosterone, and Reichstein's substance *S*, but had no effect on 21-deoxycortisone. (Chromatography for evaluation of recovery of these five substances was performed by Bush's system *B*, except that Bush's system *C* was used for aldosterone.) The order of decreasing ease of destruction was as follows: cortisone > cortisol > 11-dehydrocorticosterone > corticosterone > substance *S* > aldosterone > 21-deoxycortisone.

In order to determine the effect of ethylenediamine tetraacetic acid on the recovery of a steroid from paper chromatography, 10-μgm. samples of cortisone were chromatographed (formamide–chloroform) along two 5-cm. lines on a sheet of Whatman No. 1 paper impregnated with 30 per cent formamide and 70 per cent acetone. When the solvent front was near the bottom of the paper, zones 6 cm. high by 7 cm. wide containing the steroid were cut out and eluted chromatographically with 15 ml. of water. The water was extracted with three 5-ml. portions of chloroform. 50 μgm. disodium ethylenediamine tetraacetic acid in 5 ml. of methanol was added to one chloroform extract, and 5 ml. of methanol to the other. The solutions were taken to dryness *in vacuo*, the residues were transferred to test-tubes with 2 ml. of methanol, and the solutions were taken to dryness in a stream of carbon dioxide. The residues were dissolved in methanol and divided into one-, five- and ten-sixteenths, and taken to dryness in carbon dioxide. After standing for a day, the residues were transferred to paper, chromatographed and evaluated as above. The recoveries in the experiments with and without addition of ethylenediamine tetraacetic acid were 93 and less than 5 per cent. In similar experiments with cortisol the recoveries were 88 and 42 per cent. Detergent-washed glassware was used in these experiments.

The presence of copper and other metals in filter paper and the use of 8-hydroxyquinoline for preventing their interference in the chromatography of amino-acids have been described by Consden, Gordon and Martin[3]. Although we have not chromatographed cortisone or cortisol on paper containing chelating agents for metals, such a procedure might improve still further the recovery of these compounds. In our experience losses of cortisone and cortisol due to contaminants obtained from the glassware have been much more serious than those due to contaminants obtained from paper.

It seems probable that the destruction of cortisone and cortisol in the experiments involving the routinely washed glassware was due, at least in part, to copper. We think so because : (1) the distilled water and glassware contained significant amounts of copper ; (2) the addition of copper to specially cleaned glassware resulted in destruction of the steroids with the formation of transformation products of the same chromatographic mobility as those obtained from using ordinary glassware ; (3) the addition of ethylenediamine tetraacetic acid prevented destruction of the steroids under both sets of conditions.

Frequently, copper is present in the water (natural or distilled[4,5]), tongs, vessels, or other apparatus used to clean glassware. It seems probable that the destruction of steroids by copper may occur in laboratories other than our own.

We wish to thank Dr. Harold L. Mason for helpful suggestions during the course of this work.

Differential Effect of Phenothiazines on Oxidative Phosphorylation

In a previous communication[1] we directed attention to the biochemical effect of chlorpromazine on electron transport and the coupled phosphorylation. While studying related compounds we have observed that promethazine hydrochloride (10-(2-dimethyl amino-*iso*propyl) phenothiazine hydrochloride) exerts differential effects on the phosphorylations coupled to the reduction of cytochrome *c* by β-hydroxybutyrate and by succinate. Table 1 shows that promethazine hydrochloride inhibits the phosphorylation coupled to oxidation of β-hydroxybutyrate by 30 per cent at 2×10^{-4} and $4 \times 10^{-4}\,M$. At the latter concentration, electron transport is powerfully inhibited. The phosphorylation coupled to succinate oxidation is inhibited 50 per cent at $2 \times 10^{-4}\,M$

Table 1. EFFECT OF PROMETHAZINE ON OXIDATIVE PHOSPHORYLATION

Substrate	Concentration of promethazine × 10^{-4} M	Oxygen uptake (μgm.-atoms)	Phosphorus uptake (μmoles)	P/O	Inhibition P/O (per cent)
β-Hydroxybutyrate	nil	7·5	18·5	2·5	—
β-Hydroxybutyrate	2	6·6	10·2	1·67	33
β-Hydroxybutyrate	4	1·2	2·3	1·80	28
Succinate	nil	12·5	21·0	1·7	—
Succinate	2	12·4	10·5	0·84	50
Succinate	4	11·6	2·3	0·2	82
Ferrocytochrome *c*	nil	10·9	6·5	0·6	—
Ferrocytochrome *c*	2	9·3	0·0	—	100

Systems: Adenosine triphosphate, 0·0017 M; potassium chloride, 0·025 M; magnesium sulphate, 0·0067 M; cytochrome *c*, 2 × 10^{-5} M; sodium inorganic orthophosphate buffer, *p*H 7·2, 0·01 M; glucose, 0·03 M; hexokinase solution, 0·05 ml. Substrate 0·01 M.

Enzyme systems: For β-hydroxybutyrate oxidation, mitochondria suspended in 0·5 ml. of 0·075 M sucrose, equivalent to 1·5 mgm. nitrogen. For succinate, mitochondria, 0·5 mgm. nitrogen were suspended in 0·5 ml. of 0·02 M phosphate, *p*H 7·2, 0·25 M sucrose, in which medium they were pre-incubated for 10 min. at 30° C. For ferrocytochrome *c*, mitochondria, 2 mgm. nitrogen, were added in 0·5 ml. 0·075 M sucrose. 0·01 M ascorbate was added as reducing agent. Final vol. 3·0 ml.

Incubation temperatures were 38° C. for β-hydroxybutyrate and succinate and 20° C. for ferrocytochrome *c* oxidation.

and essentially abolished at 4×10^{-4} M, electron transport being little affected. A one-step oxidation was secured by pretreatment of mitochondria, as described by Hunter and Ford[2]. Table 1 also shows that the inhibitor abolishes the phosphorylation coupled to oxidation of ferrocytochrome *c*.

Table 2. EFFECT OF PROMETHAZINE ON PHOSPHORYLATION COUPLED TO CYTOCHROME *c* REDUCTION

Substrate	Promethazine (4×10^{-4} M)	Cytochrome *c* reduced (mμ moles)	Phosphorus esterified (mμ moles)	P/2*e*	Inhibition P/O (per cent)
β-Hydroxybutyrate	—	63·2	59·0	1·87	—

Succinate	—	53	7·3	0·28	—
Succinate	+	38	nil	—	100

System: Cytochrome *c*, 4 × 10^{-5} M; sodium inorganic orthophosphate buffer, *p*H 7·2, 0·005 M; glucose, 0·03 M; hexokinase, 0·05 ml.; sodium cyanide, 10^{-4} M; ethylenediamine tetraacetate, 10^{-3} M; adenosine triphosphate, 0·0017 M; magnesium sulphate, 0·0067 M; potassium chloride, 0·025 M; phosphorus-32 to an activity of 80,000 c.p.m. per μmole; where present, β-hydroxybutyrate was added at a concentration of 0·01 M and succinate at a concentration of 0·033 M. Temperature, 20° C. Method of determination of phosphate uptake that of Nielsen and Lehninger (ref. 3). Mitochondria (0·04 mgm. nitrogen) in 0·1 ml. of 0·075 M sucrose. Final vol. 3·0 ml.

Table 3. EFFECT OF PROMETHAZINE ON ^{32}P-ADENOSINE TRIPHOSPHATE EXCHANGE

Additions	Promethazine (2×10^{-4} M)	Phosphorus-32 counts/min. incorporated into adenosine triphosphate	Inhibition (per cent)
Nil	nil	5,950	nil
30 μmoles β-hydroxybutyrate	nil	6,070	nil
Nil	+	2,025	66
30 μmoles β-hydroxybutyrate	+	4,600	24

System: Adenosine triphosphate, 0·0017 M; inorganic orthophosphate, *p*H 7·2, 0·0033 M; magnesium sulphate, 0·0067 M; potassium chloride, 0·025 M; *tris* buffer, *p*H 7·2, 0·03 M; versene 10^{-3} M; phosphorus-32, 15,000 c.p.m. (spec. act., 1,500 c.p.m. per μmole). Time of incubation, 15 min. Temperature, 20° C. Mitochondria (1·0 mgm. nitrogen) added in 0·5 ml. 0·25 M sucrose.

The experiments recorded in Table 2 show that promethazine hydrochloride does not affect the efficiency of phosphorylation coupled to reduction of cytochrome *c* by β-hydroxybutyrate, even though electron transport is inhibited by more than 50 per cent. In this respect it resembles chlorpromazine. When cytochrome *c* is reduced by succinate, however, the phosphorylation is abolished by 4×10^{-4} M promethazine hydrochloride. It follows that promethazine selectively inhibits two sites of phosphorylation. One is that coupled to the oxidation of ferrocytochrome *c* and the other that coupled to the span succinate – cytochrome *c*. Promethazine hydrochloride also inhibits powerfully the ^{32}P-adenosine triphosphate exchange reaction. This agrees with the similar action of chlorpromazine. The inhibition is partially reversed by addition of β-hydroxybutyrate, which has no effect on exchange in the absence of inhibitor (Table 3). The inorganic phosphate-level does not alter appreciably in these experiments. This result indicates that inhibition of the exchange reaction is not due to any uncoupling effect of the compound, and suggests that the greater part of the exchange occurs between the span reduced diphosphopyridine nucleotide – cytochrome *c*.

At high concentration the phenothiazines are inhibitors of several flavoprotein enzymes, and we suggest that the difference in effect of promethazine hydrochloride on reduced diphosphopyridine nucleotide – cytochrome *c* reductase and succinate cytochrome *c* reductase reflects the difference in structure of the enzymes and lends support to the view that the flavoproteins themselves take part in the initial stages of the oxidative phosphorylation reaction.

We should also like to direct attention to the specificity of action of these compounds on oxidative phosphorylation reactions. Hitherto no compound capable of stepwise inhibition of the respiratory phosphorylations has been described.

Condensation Products of Ethylenediamine with Adrenaline

IT has been reported that adrenaline and noradrenaline are converted quantitatively into strongly fluorescent stable products by their reaction with ethylenediamine[1,2], and the fluorimetric separation determination of adrenaline and noradrenaline was devised by the use of two kinds of secondary filters, based on the difference of the fluorescence spectra of the condensation products of both catechol amines[3].

It was supposed that the separation of these condensation products by chromatography or electrophoresis and the determination of each fluorescence might be applied for the separation determination of adrenaline and noradrenaline on the basis of the ethylenediamine method. Starting from this point of view, we intended to separate the condensation products of adrenaline and noradrenaline by means of paper chromatography or paper electrophoresis, and encountered the unexpected result that one of the by-products of the condensation reaction of adrenaline with ethylenediamine was identical with the main condensation product of noradrenaline.

The sample of L-adrenaline (Merck Co.) used was examined by chromatography. When it was tested by paper chromatography using phenol containing 15 per cent (v/w) 0·1 *N* hydrochloric acid as solvent[4] and coloured by potassium ferricyanide, only one spot appeared. Only one peak was also observed by *IRC*-50 column chromatography[5]. Therefore, the presence of noradrenaline in this sample could be excluded. Using this sample of L-adrenaline, the condensation was carried out.

5 μgm. of adrenaline dissolved in 10 ml. of 0·01 *N* hydrochloric acid were added to a mixture of 1 ml. of ethylenediamine monohydrate and 0·5 ml. of 2 *M* ethylenediamine dihydrochloride, heated at 50° C. for 20 min. and extracted with 6 ml. of *iso*-butanol as reported by Weil-Malherbe and Bone[2]. In order to concentrate the fluorescent derivatives, 5 ml. of the *iso*-butanol extract were condensed under reduced pressure at about 30° C. and redissolved with a small amount of water. This sample, containing the condensation products corresponding to about 0·3 μgm. of adrenaline, was placed on a strip of Whatman No. 1 filter paper which was previously treated with 0·5 *N* hydrochloric acid and then with 0·1 per cent ethylenediamine tetraacetate[6]. The paper strip was developed in the dark, and the condensation products were examined under ultra-violet light. When the upper layer of *n*-butanol/ethanol/5 per cent $Na_2HPO_4 \cdot 12H_2O$ (50 : 25 : 30)[7] was used, the following three fluorescent spots appeared: weak violet fluorescent spot at R_F 0·32, yellow fluorescent spot at R_F 0·48, and bluish-green fluorescent spot at R_F 0·71. (When the concentration of adrenaline was increased, several other fluorescent derivatives appeared.)

The violet fluorescent spot at R_F 0·32 was considered to be derived from the substance contained in the filter paper. The reasons are as follows: (1) this spot could also be observed in the case of the blank test without adrenaline; (2) ethylenediamine, when applied on the filter paper, formed a violet fluorescent spot which is easily extractable with hot water and has the same fluorescence spectrum as that of the extract from the spot at R_F 0·32. So this violet fluorescent spot was attributed to the reaction of ethylenediamine dissolved in *iso*-butanol with the substance contained in filter paper.

The strongest yellow fluorescent spot, at R_F 0·48, was the main product which is specific for adrenaline.

The bluish-green fluorescent spot at R_F 0·71 was considered to be identical with the main spot of noradrenaline derivatives as described below.

In the case of noradrenaline, three spots were observed as follows: yellow fluorescent spot at R_F 0·04, violet fluorescent spot at R_F 0·32, and bluish-green fluorescent spot at R_F 0·71.

The strongest bluish-green fluorescent spot at R_F 0·71 was the main condensation product which is specific for noradrenaline.

The identification of the bluish-green fluorescent derivative of adrenaline (at R_F 0·71) with the main fluorescent derivative of noradrenaline was further carried out by paper chromatography using the following different solvents: the upper layer of *n*-butanol/methanol/5 per cent $Na_2HPO_4 \cdot 12H_2O$ (60 : 15 : 30)[7], the upper layer of *n*-propanol/*n*-butanol/5 per cent $Na_2HPO_4 \cdot 12H_2O$ (50 : 15 : 30)[7], *n*-butanol-saturated phosphate buffer at *p*H 6·0[8], *n*-butanol/conc. ammonia (9 : 1)[9], and 5 per cent $Na_2HPO_4 \cdot 12H_2O$.

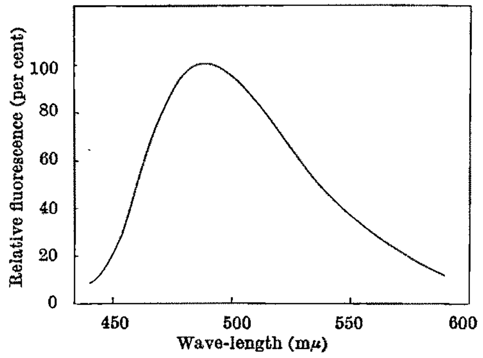

Fig. 1. Fluorescence spectrum of the main condensation product of ethylenediamine with noradrenaline and that of the by-product in the condensation of ethylenediamine with adrenaline. Samples were dissolved in *iso*-butanol, and were excited by ultra-violet radiation (365 mμ). The ordinate shows the relative intensity of the fluorescence

In each case, R_F value of the bluish-green fluorescent by-product of the adrenaline derivative agreed with that of the main noradrenaline derivative.

Paper electrophoresis was also used to examine the products. The sample was placed on the anode side of a paper strip moistened with 0·05 *M* phosphate buffer (*p*H 7·0) and 1 m.amp./cm. of constant current was applied in the dark. The violet fluorescent band derived from the filter paper moved rapidly to the cathode. Then, the main product which fluoresced yellow moved more rapidly than the bluish-green fluorescent band, which has the same rate of mobility as the main product fluorescing bluish-green of noradrenaline derivative.

As shown in Fig. 1, the fluorescence spectrum of *iso*-butanol extract of the bluish-green fluorescent spot of adrenaline derivative was identical with that of the main noradrenaline derivative. They agreed with that of the major product of noradrenaline reported by Nadeau and Joly[3].

*p*H-fluorescence curves of aqueous extracts of both derivatives were identical, as shown in Fig. 2.

These results confirm the identity of the two bluish-green fluorescent substances. Accordingly, it was considered that the condensation reaction of ethylenediamine with adrenaline gave the main

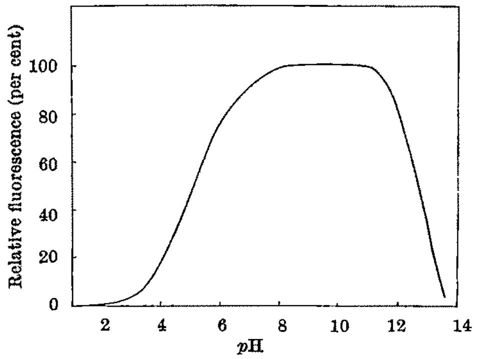

Fig. 2. *p*H-fluorescence curve of the main condensation product of ethylenediamine with noradrenaline and that of the by-product in the condensation of ethylenediamine with adrenaline. The relative intensity of the fluorescence of the substance excited by ultra-violet radiation (365 mμ) was measured at *p*H indicated. Samples were dissolved into 0·1 *M* glycine hydrochloric acid (*p*H 1–4), 0·1 *M* phosphate (*p*H 5–8), 0·1 *M* glycine sodium hydroxide (*p*H 9–13) buffers and 1 *N* sodium hydroxide

condensation product of noradrenaline as one of its by-products. This fact indicates that the demethylation of adrenaline occurs during the condensation reaction of adrenaline with ethylenediamine.

PHYSIOLOGY

Pattern of Recurrent Conditioning of Spinal Reflexes

VARIOUS functions have been suggested for the recurrent conditioning described by Renshaw[1]. Consonant with his view that the conditioning is "not obviously related to reciprocal innervation"[1], others have considered the widespread inhibitory action to serve a "generalized suppressor function"[2]; or to stabilize the impulse output in the stretch reflex at a slow rate[3]. As recurrent inhibition is prominent between the nuclei of two heads of a muscle or of two parts of a muscle group, it has been thought to help in the localization of stretch reflexes[4]. Following the finding that recurrent facilitation is evoked by activity of the cholinergic motor axon collaterals[5], as is recurrent inhibition[2], the distribution of these two actions has been re-examined. Contrary to some previous descriptions, it now appears that the distribution of recurrent conditioning displays an integrated pattern which is in some respects related to reciprocal innervation.

All experiments were performed on acutely decapitate cats in which the carotid arteries were tied off and the vertebral arteries clamped. The dorsal roots were cut from *L* 3 or *L* 4 to *S* 3, and various roots were stimulated to elicit test monosynaptic reflexes in a variety of muscle nerves. For conditioning, other muscle nerves were stimulated antidromically, the impulses entering the cord through the intact ventral roots. The preparations were immobilized by intravenously injected 'Flaxedil' (gallamine triethiodide, American Cyanamid Co.).

As Renshaw noted[1] the conditioning action between any two nerves remains essentially the same from one experiment to another. Some differences, however, do occur. Recurrent conditioning often consists of a mixture of facilitation and inhibition. In systems where facilitation is the predominant action, an early inhibitory phase may sometimes be present. When such an inhibitory phase is present, its magnitude and the conditioning-test interval at which it reverses to facilitation vary from one preparation to another. Similarly, where inhibition is predominant, it may be followed by a facilitatory overshoot. In some systems there has been a variation in the type of conditioning observed. For example, when flexor longus digitorum was used to condition the dorsiflexors of the digits, facilitation and inhibition were observed on different occasions.

One generalized finding from these experiments is that recurrent facilitation appears most often when reflexes in nerves to flexor muscles are conditioned by antidromic stimulation of nerves to extensors. When extensor reflexes are conditioned by flexor nerves there is frequently no effect, although some facilitation and inhibition have been obtained. When extensors condition extensors, or flexors condition flexors, inhibition is usually seen. In the case of interactions between muscles acting at different joints, exceptions to this general pattern have been found.

The organized pattern of the conditioning actions becomes still clearer when examined in terms of interactions of antagonists at various joints. These results are presented in Table 1.

Table 1

Joint	Nerve used to condition	Nerve used for testing	Effect
Digits	plantaris	extensor longus digitorum extensor brevis digitorum	facilitation, usually preceded by some inhibition
	flexor longus digitorum*	extensor longus digitorum extensor brevis digitorum	facilitation preceded by inhibition, or inhibition
	deep peroneal	plantaris flexor longus digitorum	weak mixed action or no effect
Ankle	gastrocnemius-soleus	tibialis anterior extensor longus digitorum	facilitation, sometimes preceded by some inhibition
	deep peroneal	gastrocnemius-soleus	little effect
Knee	quadriceps†	biceps-semitendinosus	facilitation
	biceps-semitendinosus	quadriceps	some facilitation, at times preceded by inhibition

* In all experiments flexor longus digitorum included the nerve to tibialis-posterior.
† The nerve to rectus femoris was usually removed.

At all joints studied, antidromic stimulation of the nerves to the extensors resulted in a conditioning action on the flexors which was predominantly facilitatory. Antidromic stimulation of the flexors had a facilitatory action on the extensors at the knee, but only weak indeterminate effects on the ankle and digit extensors. In the case of the ankle and digits the facilitatory action by the extensors was not restricted to their specific antagonists; stimulation of gastrocnemius-soleus, plantaris and flexor longus digitorum resulted in facilitation of all branches of the deep peroneal nerve.

Whereas antidromic stimulation of the extensors facilitates their antagonists, there is recurrent inhibition of their synergists, and frequently, of extensors at neighbouring joints. For example, it is known that antidromic stimulation of part of quadriceps inhibits the reflex in another part of the muscle[1]; the same interaction is found between the heads of gastrocnemius[1]. Antidromic stimulation of gastrocnemius-soleus inhibits plantaris and flexor longus digitorum. An inhibitory action between these latter two muscles has also been reported[2].

It has been held that the presence of recurrent inhibition between various nuclei is determined by their proximity in the spinal cord[2]. While proximity may indeed be a factor, it is not sufficient to account for all results that have been obtained. This can be seen particularly clearly in experiments involving biceps posterior-semitendinosus and biceps anterior. The motoneurons of these muscles can be shown to have the same segmental distribution in the cord and are known to form a single nucleus[6]. Yet when these nerves are used either for testing or conditioning quite different results are obtained: quadriceps consistently facilitates biceps posterior-semitendinosus but has an inconstant action on biceps anterior; biceps posterior-semitendinosus inhibits tibialis anterior, which is facilitated by biceps anterior.

In conclusion, our results support the view that recurrent conditioning in the cat spinal cord is determined by more than the location of nuclei in the ventral horn. Rather, an integrated pattern appears to be present. Where pronounced recurrent conditioning is present between muscles of a myotatic unit, this conditioning is opposite in action to the monosynaptic facilitation or direct inhibition between the same muscles. This is particularly evident when activity in flexors is conditioned by stimulation of extensors.

Effect of Morphine upon the Adrenal 17-Hydroxycorticosteroid Secretion in the Dog

It has been reported that morphine is a potent stimulus to the anterior pituitary–adrenal cortical system, as judged by indirect index such as depletion of adrenal ascorbic acid in rats[1-3]. However, little is known quantitatively of adrenal corticosteroid secretion in response to morphine. In the present investigation, experiments were carried out to evaluate directly the effect of morphine upon the secretion-rate of 17-hydroxycorticosteroids in dogs.

In order to collect the adrenal venous blood in unanæsthetized dogs, the method of Satake *et al.*[4] was used with a slight modification. About three weeks before the experiments proper, the thoracic (11)–lumbar (3) dorsal spinal roots, through which the sensory nerve fibres from the lumbar area run, were cut under 'Evipan-sodium' and ether anæsthesia. The lumbo-adrenal vein cannulation was performed without anæsthetizing the animal. Then about 18 hr. were allowed to elapse before the onset of experiments. After control adrenal venous blood samples were collected without anæsthetizing and fastening the animal, morphine hydrochloride in a dose of 8 mgm./kgm. body-weight was injected intravenously in 60 sec.

5, 10, 20, 30, 60 and 120 min. after morphine injection, the adrenal venous blood collections were also made. The plasma was separated from the sample of blood by centrifugation and was estimated for 17-hydroxycorticosteroids by use of Nelson and Samuels's method[5]. The rate of secretion was calculated by multiplying the 17-hydroxycorticosteroid content of the adrenal venous blood plasma by the adrenal plasma flow.

Table 1. Effect of Morphine upon the Adrenal 17-Hydroxycorticosteroid Secretion-Rate in the Dog

No. of experiment	17-Hydroxycorticosteroid secretion-rate (μgm./kgm./min.)							
	Min. before morphine injection		Min. after morphine injection					
	30	10	5	10	20	30	60	120
1	0·05	0·07	—	0·67	—	0·41	0·09	0·07
2	0·06	0·05	0·67	0·74	0·21	0·06	0·06	0·06
3	0·12	0·13	0·30	0·92	0·59	0·72	1·0	0·15
4	0·08	0·08	1·2	1·5	1·4	1·6	1·1	1·0
5	0·06	0·13	2·0	2·7	2·4	2·2	2·1	1·3

The results are given in Table 1.

The resting secretion-rate was measured as 0·05–0·13 μgm./kgm. body-weight/min., the mean value being 0·08 μgm. After morphine injection the secretion-rate increased invariably. Within 10 min. after the injection a remarkable increase was observed in all cases. The maximal secretion-rate after morphine was measured as 0·67, 0·74, 1·0, 1·6 and 2·7 μgm./kgm./min.

Prolonged Muscular Activity without Phosphate Exchange

Although there is a paucity of direct supporting evidence for the postulate that the immediate source of the energy for muscular contraction is the dephosphorylation of adenosine triphosphate, this view has been accepted by most authors[1-3]. The usual finding that there is no net decrease in the amount of adenosine triphosphate present in the working muscle is attributed to its rapid resynthesis by transfer of the phosphate group of phosphocreatine. However, Fleckenstein *et al.*[4] found no evidence for such transfers of phosphate groups in a tracer study on drug-induced contracture of muscles of the frog, and Dixon and Sacks[5] found no evidence for equilibration of isotopic phosphorus between the terminal phosphorus of adenosine triphosphate and phosphocreatine in the course of a tetanic contraction of the cat gastrocnemius muscle of 30 sec. duration. Nor was there any equilibration of the isotope between the middle phosphorus of adenosine triphosphate and the corresponding phosphorus of adenosine diphosphate, such as would be expected to result from mixing of any adenosine diphosphate formed during the tetanus with that initially present in the resting muscle.

The present experiments were designed to produce an even more crucial test of the postulate, by studying

Table 1. SPECIFIC ACTIVITIES OF PHOSPHORUS COMPOUNDS OF MUSCLE AFTER INJECTION OF IRRADIATED PHOSPHATE.
Stimulated muscle: at rate of three twitches per sec. for 1 hr., beginning 5 min. after intravenous injection of tracer. Results in terms of c.p.m. per mgm. phosphorus, calculated to basis of 10^6 c.p.m. injected per kgm. body-weight

Phosphorus fraction	Experiment 1		Experiment 2	
	Resting	Stimulated	Resting	Stimulated
Orthophosphate	312	263	595	460
Phosphocreatine	57	69	169	101
Terminal phosphorus of adenosine diphosphate	45	59	64	54
Terminal phosphorus of adenosine triphosphate	115	111	124	84
Middle phosphorus of adenosine triphosphate	63	71	77	68

the effect of a prolonged series of single twitches on any possible redistribution of isotopic phosphorus between these compounds. The gastrocnemius muscles of cats under pentobarbital anæsthesia were dissected free at their insertions, tracer phosphate was injected intravenously, and one muscle was attached to a lever and placed under tension. 5 min. were allowed for distribution of the tracer into the extracellular phase. The one muscle was then stimulated through the nerve at the rate of 3 twitches per sec. for 1 hr. This muscle and the companion resting muscle were then frozen *in situ* with a mixture of dry ice and ether. The various phosphorus compounds were isolated from trichloracetic acid filtrates by the ion exchange procedures used previously[5]. The terminal phosphorus of adenosine triphosphate was isolated by the action of myosin–adenosine triphosphatase, the phosphorus of the middle group of adenosine triphosphate, the terminal one of adenosine diphosphate, and of phosphocreatine were isolated by appropriate acid hydrolysis, and measurements of radioactivity made by the methods of the previous study. The samples were counted for a sufficient length of time to reduce the statistical error to less than 2 per cent.

The results of two representative experiments are given in Table 1. It can be seen that there is no significantly greater approach to isotopic equilibrium between these various phosphate groups in the stimulated muscles than in the resting ones, despite the more than 10,000 contractions and relaxations undergone by one muscle of each pair. Also, it appears that there is no increase in the total amount of phosphate transported across the cell membrane of the muscle during this rather intense and prolonged activity. The experiments in Table 1 have been selected from a larger number, all of which show the same general picture. In some, the range of specific activities is higher on the side of the stimulated muscle; in others, on the side of the resting muscle. The variations found between the two muscles of a single experiment are of the same order as was found between companion resting muscles, 1 or 2 hr. after the injection of the tracer[5].

These results, added to those from other types of experiments on surviving muscle, should make it evident that the participation of adenosine triphosphate in the mechanical event, which has been adduced from experiments on glycerinated fibres and actomyosin filaments, does not involve any dephosphorylation of the compound. Consequently, the source of the energy for the contraction process must be sought elsewhere than in the dephosphorylation of adenosine triphosphate.

Excitation–Contraction Coupling in Heart Muscle

THERE is general agreement that the membrane process activates the contractile mechanism in muscle; but up to the present all efforts to find quantitative relations between the electrical and mechanical parameters have failed.

Experiments, hitherto performed on this field, have compared the action-potential with the time-parameters or the amplitude of contraction. However, since the analysis of the mechanical properties in striated muscle[1-3] has shown that the time-course of contraction is the result of several events, it seems reasonable to suppose that only one of these may be correlated to the electrical changes on the side of the membrane.

In agreement with previous findings, our experiments have led to the conclusion that the mechanical shortening, induced by activation of the membrane, depends, in a well-defined manner, on the length of muscle. Hence, the question arises how long and to what extent this dependence is maintained in any instant during a contraction-cycle. For this reason, in several series of experiments, strips of frog and turtle ventricle and auricle have been released quickly in the resting state and during the rising and falling phase of contraction[4]. The following results were obtained.

The increase of the active recovery-peak tension after release, if corrected for the change in tension due to the elasticity of the series compliance (so-called *Aktivierung*), declines during the contraction-cycle. The time course of the *Aktivierung* has a characteristic shape in different muscles: in the ventricle a relatively long-lasting plateau during the rising phase of contraction, with a subsequent steep decline during relaxation, is observed, whereas the auricle shows a rather short plateau followed by a flat decline of the *Aktivierung*. The skeletal muscle is characterized by the absence of a plateau, and an instantaneous decline of the *Aktivierung* after the latent period.

Because of the striking similarity of the time-course of the *Aktivierung* with that of the action-potential in all preparations investigated we have studied the time-course of both *Aktivierung* and action-potential, the latter by a routine extracellular method[5].

In Figs. 1 and 2 the time-course of the *Aktivierung* and the repolarization phase of the action-potential is given for a frog ventricular strip (Fig. 1) and a turtle auricular strip (Fig. 2). The zero point of the diagrams is the beginning of the rising phase of the isometric contraction. The electrogram is shifted towards the same zero point, so that the electro-

Resting tension before release, 9·0 gm.; peak tension, 27·0 gm. Release = 0·48 mm. = 2·45 per cent l_0; duration of release, 0·016 sec.; peak time of isometric contraction, 1·5 sec. Further details as for Fig. 1

mechanical latency is neglected. For practical reasons, the rising phase of the action-potential is not considered in the diagram. In both preparations, the rate of repolarization is greater than the decline of the *Aktivierung*. However, if the time-scale of the action-potential is enlarged by a factor 1·4, both curves coincide.

The same result was obtained in 20 experiments in a range of temperature of 0–10° C. and of rate of stimulus of 2·5–10/min. The change in temperature and stimulus frequency has the same effect on both curves (Fig. 3). The time factor may vary in different experiments from 1·1 to 2·2, the mode being 1·4. A simple explanation of this change in time-scale results from the fact that the time-course of the extracellular action-potential is quickened, if led off in Ringer solution, in comparison with that recorded in air[6]. We conclude from our findings that the action-potential governs the contractile process via the rate of *Aktivierung* in any instant. How the normal time-course of contraction is correlated with the mechanical event of *Aktivierung* is still an open question.

Oxygen Equilibrium of Human Hæmoglobin in Strong Salt Solutions

It has been reported by several authors that human hæmoglobin dissociates into sub-units in strong salt solutions (that is, in sodium chloride above 0·5 *M*). The decrease of molecular weight of hæmoglobin in such conditions was demonstrated by sedimentation[1,2], osmotic-pressure[3] and light-scattering[4] methods. According to present views[5] on the oxygen equilibrium of mammalian hæmoglobins, the decrease in the molecular weight of hæmoglobin (and therefore the decrease in the number of the oxygen-combining centres per molecule) should be accompanied by alterations of the shape of the oxygen equilibrium curve. Taking the value of n in the Hill empirical equation:

$$Y = \frac{K(pO_2)^n}{1 + K(pO_2)^n}$$

as a measure of the sigmoid character of the curve, this value should be lower than 2 for a splitting of hæmoglobin into halves[5].

While investigating the mechanisms involved in the oxygen equilibrium of hæmoglobin, it seemed, therefore, interesting to study the effect of high salt concentrations on the oxygen dissociation curves of human hæmoglobin.

The oxygen dissociation curves were determined by the spectrophotometric method previously described[6]. Human hæmoglobin was prepared from freshly drawn blood; the erythrocytes were washed several times with 1 per cent sodium chloride solution and finally hæmolysed with water. The hæmoglobin solution was centrifuged at 20,000 r.p.m. for 30 min. and then dialysed for 48 hr. against de-ionized water.

The oxygen equilibrium of human hæmoglobin in the presence of 0·3 *M* phosphate buffer alone and plus added salts, at pH 7 and 20° C., is given in Table 1 and Fig. 1. The results demonstrate that in high salt concentrations even for dilute hæmoglobin solutions, the oxygen equilibrium curves do not show a decrease but rather an increase in the value of n. Indeed, in conditions in which the hæmoglobin molecule should be split into halves the value of n was near or greater than 3. In strong salt solutions an

Table 1. Oxygen Equilibrium of Human Hæmoglobin in Strong Salt Solutions

Salt added	Final molarity of the salt added	log $p\frac{1}{2}$	n
None	—	1·04	2·9
None	—	1·08	2·9
Potassium chloride	2	1·18	3·0
Potassium chloride (After 24 hr.)	2	1·14	2·9
Potassium chloride	1	1·15	2·9
Potassium chloride	0·5	1·12	2·9
Sodium chloride	2	1·11	2·95
Tris-hydrochloric acid	2	0·92	3·0
Sodium sulphate	1	1·07	3·0
Sodium citrate	1	1·05	3·05
Potassium dihydrogen phosphate-dipotassium hydrogen phosphate	1	1·03	3·1

Hæmoglobin $2 \cdot 5 \times 10^{-4}$ *M* (as iron); *p*H 7; 20° C.; potassium dihydrogen phosphate–dipotassium hydrogen phosphate buffer 0·3 *M*. $p\frac{1}{2}$ = oxygen pressure in mm. mercury for 50 per cent oxygen saturation. The value of n (in the Hill empirical equation) was calculated by the slope of the curve of log $\frac{(HbO_2)}{(Hb)}$ versus log p, near 50 per cent saturation. The salt and the buffer were usually added 30 min. before the experiments.

apparent discrepancy can be seen between the shape of the oxygen equilibrium curve and the estimated number of hæms per molecule. This finding seems to be of importance to the interpretation of the oxygen equilibrium of hæmoglobin.

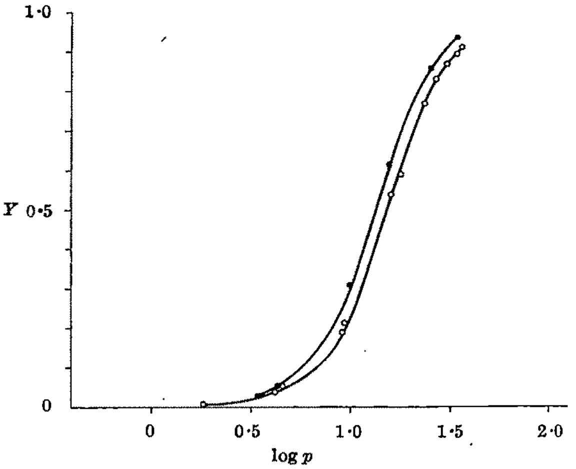

Fig. 1. Oxygen equilibrium curves of human hæmoglobin in 0·3 *M* phosphate + 2 *M* sodium chloride (●) and in 0·3 *M* phosphate + 2 *M* potassium chloride (○). *p*H 7, 20° C. hæmoglobin $2 \cdot 5 \times 10^{-4}$ *M* (as iron)

A more detailed study of the effect of salts on the functional and molecular properties of human hæmoglobin will be reported elsewhere.

A Possible Vitamin E Deficiency occurring in a Herd of Pigs fed Standard Rations in the Tropics

At the Sigatoka Agricultural Station in the Fiji Islands, it had been noted that an occasional baby piglet was born exhibiting symptoms of muscular weakness and inco-ordination in one or more legs. These piglets were born in litters from both pure and cross-bred sows and gilts of the Tamworth, Berkshire and Large White breeds.

As the clinical symptoms were somewhat similar to those described by workers in the temperate zone as occurring in lambs suffering from 'stiff lamb disease' and calves with 'white muscle disease' (Blaxter and Brown[1]), and in piglets born to sows fed on a vitamin E deficient ration (Adamstone *et al.*[2]), it was decided to test the effect of the administration of synthetic vitamin E. In late 1954 two piglets that were particularly severely affected were drenched with 50 mgm. of vitamin E at two days of age. They both effected a dramatic recovery, all clinical symptoms of the condition disappearing within 48 hours of treatment.

This suggested that the symptoms of muscular weakness exhibited by piglets might be due to a vitamin E deficiency in the sows: a very surprising conclusion, as the breeding stock in the station herd were managed in a normal manner in concrete sties and were fed on rations consisting of:

Coconut meal	40 or 45 parts	Molasses	10 or 20 parts
Rice bran	40 or 30 parts	Meat meal	10 or 5 parts

together with a mineral mix and adequate green feed. It is usually considered that a ration of this type contains sufficient vitamin E to meet the normal requirements of farm animals in almost any circumstance. Unfortunately, it was not possible to analyse the rations for vitamin E content.

In order to test the assumption that for some reason the sows might be deficient in vitamin E, all breeding stock due to farrow during 1955 and 1956 were divided at random into two groups. One group received 250 or 500 mgm. of synthetic vitamin E in one massive dose three weeks prior to the expected date of farrowing, while the other group were untreated and acted as a control. Management and feeding of the two groups were identical.

Details of the number of live and stillbirths and of the number of piglets exhibiting the clinical symptoms of muscular weakness were recorded for two years. The results are given in Table 1.

In March 1956 a female piglet born in the control group, and exhibiting symptoms of muscular weakness, was removed from the litter at two days of age and killed, and histological specimens were prepared from the lung, kidney, heart muscle, thigh muscle, shoulder muscle, tongue, abdomen, spleen, liver, brain, suprarenals, uterus, brachial plexus and sciatic nerve.

Table 1. Number of Piglets Born Alive, Still-born and Exhibiting Clinical Symptoms of Muscular Weakness during 1955 and 1956

Group	No. of litters	No. born alive: Total	Per litter	No. still-births: Total	Per litter	No. with muscular weakness
Control	27	228	8·44±0·50	17	0·63±0·03	6
Vitamin E supplemented	27	246	9·11±0·65	8	0·30±0·14	0

These specimens were examined during 1957 at Cornell University by Dr. Peter Olaffson, who failed to find any indication that the piglet may have had muscular dystrophy lesions.

Thus results to date indicate that vitamin E supplementation of sows and gilts in Fiji, receiving what would be considered a normal farm ration, apparently eliminated the birth of piglets exhibiting clinical symptoms of muscular weakness, and in addition decreased the number of still-births per litter and increased the number of piglets born alive, though these effects were not quite statistically significant. Also the addition of vitamin E to the diet of two baby piglets exhibiting the muscular weakness resulted in their dramatic recovery. Histological examination of tissues from one affected piglet failed to disclose any signs of muscular dystrophy lesions.

It is considered that the balance of evidence is in favour of the theory that there was some form of vitamin E deficiency in the breeding stock. So far as is known, no one has previously reported symptoms of vitamin E deficiency in a herd of pigs fed standard type rations, though Gorham *et al.*[3] and Davis and Gorham[4] have reported a condition known as 'yellow fat' disease in pigs fed on a rather unusual ration of fish scraps, which responded to vitamin E supplementation of the ration, and which is probably caused by excessive amounts of unsaturated fatty acids in the diet. Obel[5] has also reported that death from liver dystrophy is high in pigs in Sweden aged 3–15 weeks, where 6 per cent of cod-liver oil is fed in the ration, and that this disease is prevented by substituting lard for cod-liver oil and supplementing the ration with vitamin E.

The rations fed to the pigs in Fiji contained a high proportion of coconut meal which was usually slightly rancid. As the oxidation of vitamin E is especially rapid in foods containing high levels of unsaturated fatty acids or rancid fats together with minerals that catalyse the oxidative reactions, it is possible to postulate that the available vitamin E in the ration was being oxidized. This theory is supported by a report from Jamaica by McDonnough[6], who states that two calves fed on irrigated grass with a concentrate supplement of coconut meal that may have been rancid died, the post-mortem examination revealing that they were suffering from 'white muscle disease'. It is hoped to investigate this theory further at this establishment.

I am indebted to the Director of Agriculture, Fiji, for providing facilities for this work and for permission to publish it, to Dr. Peter Olaffson, of Cornell University, for the histological examinations, and to Mr. R. K. Naidu for the completion of the experiment while I was on leave.

Cardiac Output in Cattle

The determination of cardiac output by the dye dilution techniques requires the taking of serial arterial blood samples at short regular intervals. Direct puncture of the brachial artery of cattle[1] enables such samples to be collected. *T*.1824 (Evans blue) was injected into the jugular vein of the subjects at a dose of approximately 0·40 mgm./kgm. body-weight and arterial blood samples collected at 1-sec. intervals for a period of 30 sec. Adopting the procedure described by Hamilton *et al.*[2] the average concentration of the dye in the arterial blood samples was found, together with the time required for one circulation of the dye and the cardiac output calculated from the formula:

$$\text{cardiac output} = \frac{60 \times \text{amount } T.1824 \text{ injected}}{\text{mean concentration } T.1824 \times \text{circulation time}}$$

The subjects were allowed to settle in their surroundings for some time prior to making a determination, and during the manipulative procedures excitement of the subjects was avoided so far as possible. Pulse-rates were taken during injection of the dye and collection of arterial blood samples; and during the procedure on each animal the pulse-rate remained within the normal range of 65–90 beats per min.

Twenty-six cardiac output determinations were made on 22 female Ayrshire cattle of body-weight 100–605 kgm. The outputs ranged from 12 to 68 l. of blood per min. which, when calculated as output of blood in ml./kgm. body-weight per min., give a mean value of 113 ml. with an *S.D.* ± 11·0 ml.

The result calculated for cattle as cardiac output of blood in ml./kgm./min. is similar to that obtained in sheep by Schambye[3] using a dye-dilution technique and by Cross *et al.*[4] using the Fick method. It also compares with the value obtained by Barcroft *et al.*[5] using the Fick method on goats. Doyle *et al.*[6] used the Fick method on three adult cows to determine the cardiac output and found a mean value of 44 l./min. but made no mention of the breed or weight of the animals.

Production of Acute Insulin Deficiency by Administration of Insulin Antiserum

The diabetic syndromes observed in experimental animals and in man are due to metabolic abnormalities induced directly or indirectly by insulin deficiency and to lesions which affect tissues other than the β-cells of the islets of Langerhans. It is difficult to

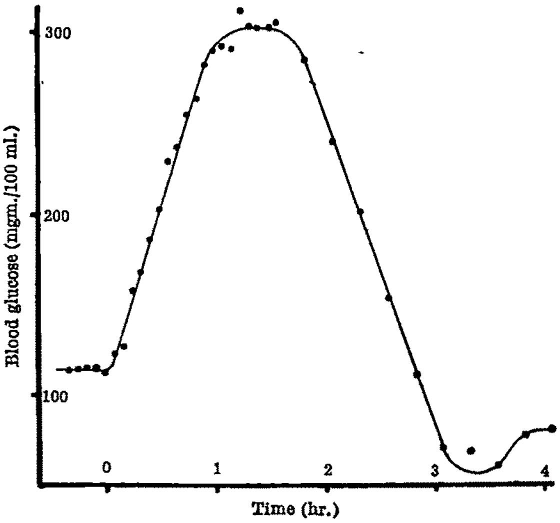

Fig. 1. Concentration of glucose in the blood of a conscious female rabbit (2·65 kgm.) following the intravenous injection at zero time of serum (2·7 ml.) from guinea pigs sensitized to bovine insulin

attribute the pathological effects observed in these syndromes to specific lesions since the methods at present available do not render animals rapidly and reversibly insulin-deficient without provoking other complicating effects.

Such a method has now been devised and is based on observations originally published by Moloney and Coval[1]. They showed that serum from guinea pigs sensitized to insulin (insulin antiserum) protects mice from the convulsive action of the hormone. It also induces hyperglycæmia 1 hr. after injection into mice and produces a diabetic syndrome with ketonuria and loss of body-weight if the injections are repeated for 3 days. It was then found[2] that the stimulant action of insulin upon the isolated rat diaphragm can be abolished if such serum is added to the incubation medium. These effects are thought to be due to the presence in the serum of antibodies which are specific but not species-specific for insulin.

In the present investigations, intravascular injection of a single dose (1·0 ml./kgm.) of serum from guinea pigs sensitized to bovine insulin has been shown to produce an immediate rise in the concentration of glucose in the blood of the anæsthetized (nembutal) or conscious rabbit. This rise, which is detectable within 5 min. of the injection, continues at a uniformly rapid rate for 30–50 min. The glucose concentration reaches a maximum (200–300 mgm./100 ml.) in 1–2 hr., and returns to the resting-level (80–110 mgm./100 ml.) in 3–5 hr.; the result obtained in a typical experiment is shown in Fig. 1. The effect produced by a slightly larger dose (2 ml./kgm.) injected into the rat is more transient, the hyperglycæmia being maximum in 30–60 min. and complete in 60–90 min. Normal guinea pig serum has no such effects on injection into rabbits or rats.

Using a technique previously described[3] it was found that plasma obtained from hyperglycæmic rabbits 1 hr. after injection of the insulin antiserum does not stimulate glucose consumption by the isolated rat diaphragm. It was concluded, therefore, that insulin, the effects of which were detected in rabbit plasma prior to injection of the insulin antiserum, had been neutralized and that the hyperglycæmia was due to absence of circulating insulin. The rabbits used in these experiments had one ear chronically denervated and the vessels of these denervated ears remained dilated throughout; endogenous adrenaline secretion was not, therefore, responsible for the hyperglycæmia. The glucose entering the blood-stream is probably derived from the liver, for whereas a marked rise in blood glucose concentration follows injection of insulin antiserum into the fed rat, only a small and gradual rise occurs if the store of liver glycogen is first depleted by fasting for 24 hr.

Assuming that the extracellular space occupies 20 per cent of the body-weight, it can be deduced from the results of the present experiments that during the initial stages of the hyperglycæmia glucose enters this space at the rate of approximately 1 mgm./min./100 gm. body-weight. This figure, which probably represents the rate at which glucose is consumed by tissues under the influence of circulating insulin, is of the same order as the glucose turnover-rates determined previously in normal rats and dogs by means of injections of glucose labelled with carbon-14 [4–6]. The rapid and transient action of this insulin antiserum suggests that endogenously secreted insulin exerts its effects rapidly and that these effects are of brief duration.

By contrast the methods currently used to produce diabetes in laboratory mammals[7,8] are often technically difficult. The syndromes are all characterized by injury, destruction or removal of the insulin-secreting cells of the pancreas, but in addition the syndrome due to insulin deficiency is complicated by the effects of other lesions; after pancreatectomy or treatment with alloxan, for example, structures other than the β-cells of the islets of Langerhans are removed or damaged. In most cases the diabetic state is not reversible, and the animals have to be maintained by parenteral insulin therapy. Withdrawal of insulin in such cases does result in the development of the diabetic syndrome, but the rate at which this occurs depends upon the nature of the insulin preparation used and at best only a gradual rise in the concentration of blood glucose is observed over a period of hours. The method described above has the great advantage that it produces hyperglycæmia rapidly and is technically simple. In addition, the hyperglycæmia is reversible, is due to insulin deficiency, and cannot be attributed to any non-specific effect of the proteins in guinea pig serum.

A more detailed account of these investigations, which are being carried out in co-operation with Dr. R. T. Grant and Mr. J. Armin, will be published elsewhere.

RADIOBIOLOGY

Changes in the Electron Spin Resonance Spectrum of Glycine with Increasing Doses of Radiation

It has been reported[1] that paramagnetic centres are produced in glycine by equal doses of γ-rays, fast neutrons and α-particles in the proportions 1 : 0·7 : 0·1. As the lower efficiency of the α-particles might well be due to the high linear energy transfer along their tracks, an investigation of the effects of very high doses of electrons on the electron spin resonance spectrum of glycine and related substances seemed worth while.

For irradiations we used a 1·5-MeV. Metropolitan-Vickers linear accelerator capable of delivering approximately 10^4 rads per pulse at the position of the sample of deoxyribonucleic acid, the duration of a single pulse being 2 μsec. Derivatives of the microwave absorption against magnetic field strength were recorded. The electron spin resonance spectrometer used for this work operates on 9,350 Mc./s. and utilizes heterodyne detection of an audio-modulated signal.

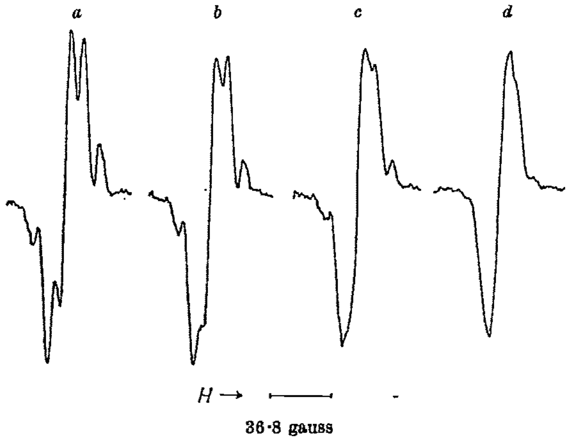

Fig. 1. Derivative of absorption signal of glycine, irradiated in air with *a*, 20 Mrads ; *b*, 50 Mrads ; *c*, 100 Mrads ; *d*, 200 Mrads

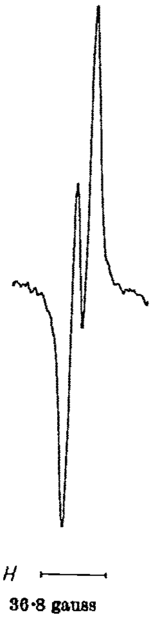

Fig. 2. Derivative of absorption signal of gelatine irradiated in air with 20 Mrads

In glycine which has received a dose of 20 Mrads the differential curve shown in Fig. 1*a* is obtained, displaying five peaks, whereas with still lower doses of the order of kilorads, triplets have been observed[2].

Increasing the dosage from 20 Mrads to 200 Mrads changes the shape of the absorption curve in a manner shown in Fig. 1*a*–*d* until only a broad single peak is left.

In gelatine, however, as in other substances containing glycine as glycylglycine[3], a double peak shown in Fig. 2 is obtained, which does not change in the same range of doses. The paramagnetic centre which causes this double peak may be identical with that which causes the two large side peaks in glycine. The central peak, on the other hand, may be due to a different centre, which is produced more efficiently at high doses. The two side-peaks would in this way vanish progressively in relation to the central peak.

One of us (A. M.) is indebted to Dr. L. H. Gray for his hospitality and to the Institute of Radiobiology, Reactor Station, Karlsruhe, for a travel grant.

Electron Spin Resonance in Irradiated Deoxyribonucleic Acid

Radiation-induced electron spin resonance in deoxyribonucleic acid has already been briefly reported[1]. We have studied the electron spin resonance spectra of samples of deoxyribonucleic acid irradiated *in vacuo*, in air and in nitric oxide. These gases are known to affect electron spin resonance signals[2,3] and to influence biological effects of radiation[4,5].

The deoxyribonucleic acid was kindly provided by Prof. J. A. V. Butler. It had been prepared from calf thymus and contained 0·7 per cent by weight of protein and, when exposed to room air, some 15 per cent of water. Pulses of electrons from a 1·5-MeV. Metropolitan-Vickers linear accelerator were used for irradiating the samples, the pulse duration being 2 μsec. and the dose per pulse about 10^4 rads. Total doses up to 10^8 rad were given in some experiments. The electron spin resonance spectrometer operated at 9,350 Mc./s. and employed heterodyne detection of an audiomodulated signal. First derivatives of the absorption curves were recorded.

The samples were placed in thin-walled glass tubes in which they could be kept under vacuum before, during and after the irradiation. They were irradiated in one part of the tube and then slid along to the unirradiated end before testing in the electron spin resonance spectrometer. The high doses were given in many short bursts, separated by long enough intervals to prevent overheating of the material.

If the samples were dried *in vacuo* for 24 hr. prior to irradiation and were then irradiated either *in vacuo* or in the presence of dry air or nitric oxide a good

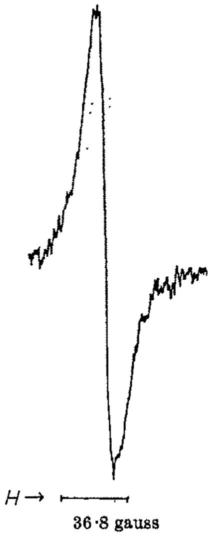

Fig. 1

electron spin resonance signal was observed in all cases. An example is shown in Fig. 1. If the sample was kept in a dry atmosphere, the signal did not decrease appreciably in a week. The decay of resonances reported by other workers[6] may have been due to the presence of moisture in the gases used, an effect which has been observed in some biological materials[7]. When moisture was present in our experiments at the time of irradiation, however, we were unable to detect any electron spin resonance signal even with a dose of 10^8 rads.

We are indebted to Prof. J. A. V. Butler for the samples of deoxyribonucleic acid used and to Dr. L. H. Gray for his encouragement and for many useful discussions.

Protective Effect of β-Aminoethylthiosulphuric Acid against Ionizing Radiation

It was recently demonstrated that thiosulphate esters rapidly react with protein sulphydryl groups to give mixed disulphides[1]. As Eldjarn and Pihl[2] have attributed the protective properties against radiation of certain sulphur compounds (for example, cysteamine, cystamine) to their ability to form mixed disulphides with active sulphydryl or disulphide groups in the cell, the possibility was considered that thiosulphate esters may be active protectors against ionizing radiation.

This has now been verified with β-aminoethylthiosulphuric acid[3], and the protecting effect of this compound has been compared with that given by cysteamine. The acute toxicity of β-aminoethylthiosulphuric acid (determined as *LD*50 by intraperitoneal injection into 50 albino mice according to Miller and Tainter[4]) was found to be 0·90 ± 0·02 gm./kgm. body-weight, whereas the *LD*50 of cysteamine hydrochloride determined by the same technique was obtained as 0·50 ± 0·01 gm./kgm. body-weight. Cysteamine hydrochloride is then about 2·4 times as toxic as β-aminoethylthiosulphuric acid, calculated on an equimolar basis.

The protective effect of β-aminoethylthiosulphuric acid on mice, irradiated with a lethal dose of X-rays, as compared with that of cysteamine hydrochloride, is shown in Fig. 1 (each compound was injected at a dose corresponding to 0·5 *LD*50). It is evident that β-aminoethylthiosulphuric acid increases both the time and rate of survival, although the latter showed a smaller increase than in mice injected with cysteamine. The possibility that the protection given by β-aminoethylthiosulphuric acid is due to cystamine or cysteamine, formed from β-aminoethylthiosulphuric acid in the body, cannot be excluded, but appears unlikely from previous *in vitro* studies on β-aminoethylthiosulphuric acid[1].

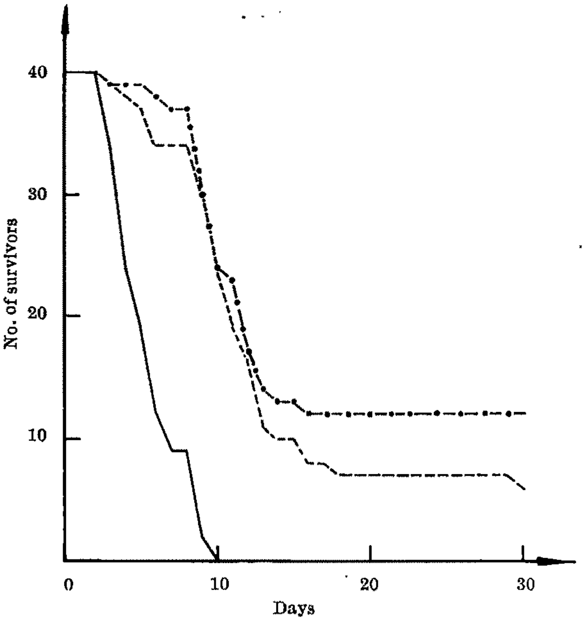

Fig. 1. Protective effect of β-aminoethylthiosulphuric acid and cysteamine against X-rays. Male albino mice exposed to 1,000 r. Protective compounds injected intraperitoneally 15 min. before irradiation. Without protector, ———; β-aminoethylthiosulphuric acid, 0·45 gm./kgm. body-weight, – – – – – –; cysteamine hydrochloride, 0·25 gm./kgm. body-weight, –.–.–.–

Leucocytosis in Response to Bacteræmia as a Feature of the Acute Radiation Syndrome in the Plaice

Bacterial invasion of the blood-stream is a marked feature of the acute radiation syndrome in the mammal following exposure to mid-lethal and supra-lethal doses of ionizing radiation[1-6]. It is generally considered that the bacteria are enteric in origin and that they gain access to the blood-stream through failure of the host defence mechanism, following the radiation insult, that is, ulceration of the gastro-intestinal tract, and leucopænia[1,7]. According to Bennett *et al.*[3] death attributable to such infection of the blood-stream in dogs is always associated with leucopænia, and Cronkite and Brecher[6] consider that the body of evidence available appears to establish

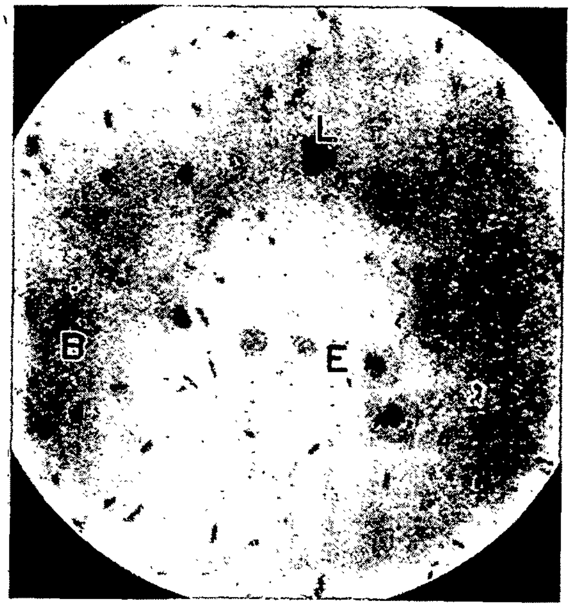

Fig. 1. Blood smear from plaice dying after exposure to 8,000 r. Note large numbers of bacilli (*B*), nucleated erythrocytes (*E*) and large numbers of leucocytes (*L*)

a firm correlation between granulocytopænia and susceptibility to infection in radiation injury.

During a series of experiments to determine the median lethal dose for plaice, exposed to 250-kV. X-rays (Morgan, F., unpublished results), bacteræmia was observed in association with leucocytosis in two fish which had received 8,000 r. (Fig. 1).

These fish died 45 and 51 days after exposure, and both were examined within a few minutes of death, blood being removed by cardiac puncture. Their relative hæmatological values are given in Table 1. The normal ratio of erythrocytes to leucocytes in the place is 40 : 1 ; in these fish the ratio was approximately 1·2 : 1, a substantial degree of leucocytosis. The anæmia revealed by the results in Table 1 is consistent with the extensive hæmorrhages that were visible in the viscera of both animals and in particular in the duodenum and small intestine, where the extravasated blood present in the lumen indicated considerable damage to the gastro-intestinal tract.

A feature of the acute radiation syndrome in cold-blooded vertebrates is the extended period between exposure and the onset of symptoms[8]. A leucopænic condition might not have been established in these fish at the time of infection, thus perhaps facilitating the response of the leucocytes to the infection. That this is unlikely is shown by the results of an autopsy carried out on a fish exposed to 2,000 r. and dying 56 days after exposure, which revealed a considerable leucopænia, with an erythrocyte to leucocyte ratio of 252 : 1. It seems probable, therefore, that the ability of plaice leucocytes to respond to bacterial invasion of the blood-stream, following exposure to acute doses of 250 kV. X-rays, may be a major difference between the development of the mammalian acute radiation syndrome and that of the plaice.

Table 1. HÆMATOLOGICAL VALUES OF THE TWO FISH EXPOSED TO 8,000 R. COMPARED WITH THOSE OF NORMAL FISH

Fish	Packed cell vol. (per cent)	Red blood count (10^6 mm.^{3})	Hb. (gm./100 ml.)
Normal	21·8	2·02	5·66
σ	3·0	0·28	0·88
8,000 r. Day 45	10·4	0·81	3·63
8,000 r. Day 51	6·5	0·49	3·22

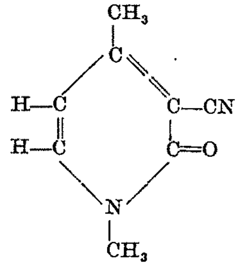
BIOLOGY

A Chromatographic Analysis for Ricinine

RICININE, the alkaloid of castor bean plants, is of interest since it is one of the very few natural products containing a nitrile group and since, as Leete and Leitz[1] have shown, it is biogenetically derived from the vitamin, nicotinic acid. In our studies on the distribution and biogenesis of ricinine we have sought a semi-quantitative analytical method that would permit routine determination of ricinine in a large number of samples of plant tissue without tedious extraction and isolation procedures. Such a goal is hindered since ricinine is neutral and does not react with the usual 'alkaloidal reagents'.



Pure ricinine was prepared from castor bean press cake by Evans's method[2]. Approximately 150 mgm. of ricinine were obtained from 1 kgm. of press cake. The characteristic ultra-violet absorption spectrum of ricinine has not been previously reported in the literature and is presented in Fig. 1. In the absence of interfering substances (for example, in the chloroform extract as obtained by Leete[1]) it would be feasible to use the absorption at 315 mμ as a quantitative measure of ricinine (*E*(1 per cent, 1 cm.) = 450). The absorption spectrum of the 2-pyridone of N-methylnicotinamide has been reported by Pullman and Colowick[3] to show a maximum at 325 mμ, somewhat higher than ricinine.

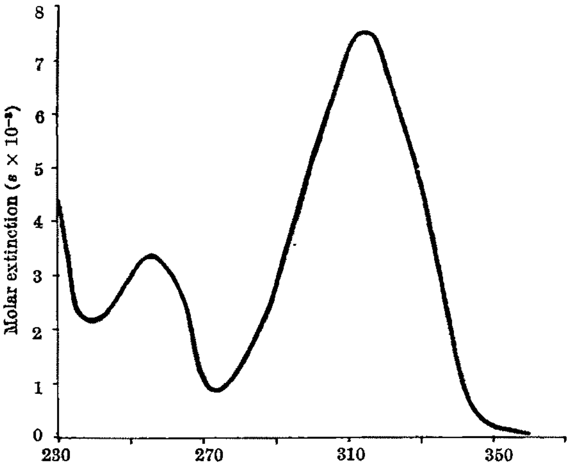


Fig. 1. Absorption spectrum of ricinine

Various solvents and spray reagents were studied for the paper chromatography of pure ricinine, using the ascending method. The most desirable solvent systems with regard to spot mobility and compactness were found to be *t*-butyl alcohol/water/acetic acid, 4 : 2 : 1, and *iso*propyl alcohol/toluene/acetic acid/water, 5 : 10 : 1 : 1, the latter being more satisfactory. The respective R_F values in these two systems were 0·75 and 0·55. The only satisfactory spray was found to be potassium tetraiodobismuthate as prepared by the method of Bregoff *et al.*[4]. This reagent gave orange spots against a yellow background. As little as 10 μgm. of ricinine could be detected, but quantitative estimation based on spot area was most successful between 20 and 100 μgm. Related compounds and possible ricinine precursors were easily distinguishable from ricinine. Nicotinonitrile and 3-hydroxyanthranilic acid gave no colour with the spray reagent though oxidative browning of the 3-hydroxyanthranilic acid spot occurred over a period of days on unsprayed chromatograms. Nicotinamide showed pink-orange coloured spots below ricinine in the latter solvent. N-methyl nicotinamide showed a pink-orange coloured spot above ricinine in the latter solvent.

The application of the above technique to plant tissues has shown remarkably little interference. It has been possible to squash small amounts of fresh tissue directly on the paper at the origin, develop with solvent, dry and spray. No spots other than ricinine have ever been observed from normal castor bean plants. Fig. 2 plots the variation in ricinine content of various organs against the total fresh weight of a plant. Because of the limited number of plants used, these results are intended merely to illustrate application of the method; however, they generally agree with the observations of Bogdashevskaya[5], who found that the percentage of ricinine in whole plants increased up to 20 days, while in individual leaves the rate of formation was greatest in the youngest leaves.

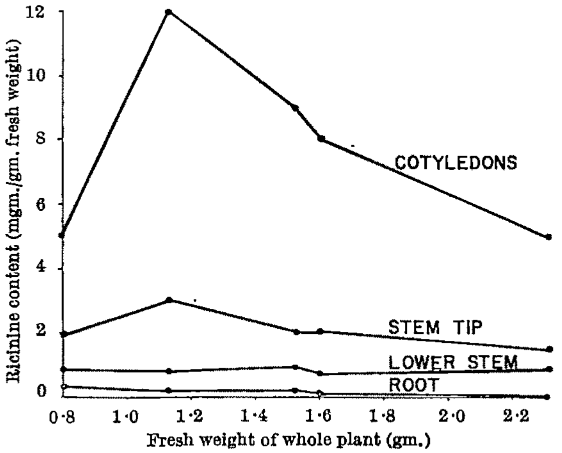

Fig. 2. Ricinine content of organs from different sizes of castor bean plants

We wish to thank the Baker Castor Oil Co., Bayonne, N.J., for supplying us with the castor bean press cake.

Mitosis in the Microspore of *Encephalartos barteri* Carruth.

THE haploid chromosome number of *Encephalartos barteri*, observed at the first division of the microspore nucleus, is 9. The chromosomes are large; the largest is about 20μ long, the smallest about 10μ long. One of the longest chromosomes has a trabant (Fig. 1). The haploid number of 9 chromosomes has already been found in the six other species of the same genus which have been examined, and in species of *Zamia*, *Bowenia*, *Dioon* and *Macrozamia*[1].

Male cones of a late crop were collected in September from a plant growing in a garden in Ibadan, Nigeria. The microsporangia then contained uninucleate microspores. A cone was kept on a bench in the laboratory, and three scales were fixed each day in 1 : 3 acetic alcohol. The first pollen divisions were found after about three weeks.

The two mitoses, producing three nuclei, occur in quick succession. After the first division, the prothallial cell takes up a peripheral position while the other nucleus divides again. After the second division, in which the chromosomes are smaller than in the first, the generative cell comes to lie next the prothallial cell, which it resembles, while the tube nucleus lies centrally in the pollen grain, and remains larger and less dense than the other nuclei.

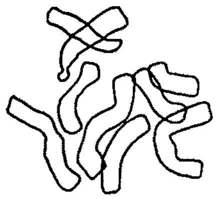

Fig. 1. The chromosomes of *E. barteri* at the first pollen mitosis; acetocarmine preparation. (× 625)

Every microsporangium contains a small percentage (about 0·1 per cent) of abnormal pollen grains. These are oval, and each apparently represents two normal grains. There is a single nucleus, and at the first mitosis there are about 18 chromosomes.

Relationship between *Dictyocotyle* and *Calicotyle*

RECENTLY, the opinion has been expressed that the endoparasitic monogenetic trematode *Dictyocotyle coeliaca* is simply a cœlomic form of the common cloacal parasite *Calicotyle* which has entered, through the abdominal pores, the body cavity of certain species of *Raia*[1]. The normal posterior adhesive organ ('opisthaptor') was thought to be lost, and its central boss to regenerate a 'pseudohaptor'. The evidence given in support of this supposed ontogenetic migration was : (1) the finding, in an abdominal canal, of a trematode which had lost its opisthaptor ; (2) the recovery, from the cloaca, of six isolated opisthaptors each with a central perforation which matched the boss of the mutilated specimen.

In expressing the above opinion, Dawes and Griffiths appear to have ignored several differences between *D. coeliaca* and *C. kroyeri*[2,3]. To these previously recognized differences may be added the following. There is a characteristic difference in the shape and size of the egg capsule, as may be seen by comparing the illustrations by Hunter and Kille[2] of *D. coeliaca* and by Dawes[4] and by Euzet[5] of *C. kroyeri*. I have confirmed this difference by examining hundreds of capsules from each of the two parasites, and the difference in the egg capsules is accompanied by a corresponding difference in the size and shape of the respective ootypes. Furthermore, there is a difference in the relationship of the length of the sclerotized penis to the length of the body proper in each of the two parasites as illustrated in Fig. 1, which is based on measurements taken from a random sample of 10 cloacal and 10 cœlomic parasites from Plymouth rays[3].

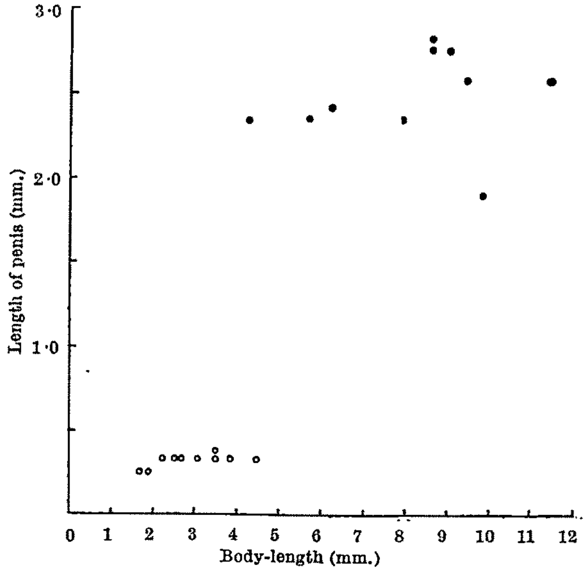

Fig. 1. Relative lengths of penis and body-proper (excluding posterior adhesive apparatus) in some monogenean parasites of *Raia* species : ●, from cœlom ; ○, from cloaca

It is conceivable that some of the differences between the cloacal and cœlomic parasites, for example, the development of diverticula from the intestinal cæca, and the lobing of the proximal region of the ovary, could possibly result from normal growth. But some other differences, for example, the re-orientation of the vaginæ and of the intestinal cæca, and the change in shape of the ootype, would involve a drastic re-organization of the body. Such a re-organization is not suggested by what is in fact known about the ontogenetic development of *D. coeliaca*. Hunter and Kille[2] have observed three young specimens (1·4, 2·2 and 2·5 mm. long respectively) in which the course of the intestinal cæca was as in the adult. Moreover, the posterior adhesive organ in these three very small specimens (compare the measurements with those given in Fig. 1), together with that in a fourth specimen only 0·57 mm. long, was of the *D. coeliaca* form, that is, having numerous shallow loculi.

C. kroyeri from the cloaca is known to produce egg capsules that yield larvæ[5]. Why then should the animal, after producing such capsules, indulge in something approaching a metamorphosis, migrate to a new ecological niche, and there produce further egg capsules ? Such a pattern of life-cycle would be, so far as I am aware, unique in the animal kingdom. Phylogenetically, the adoption by *D. coeliaca* of a habitat completely within the host could well have been by way of the abdominal canals from the cloaca to the cœlom—indeed this seems probable, and *D. coeliaca* and *C. kroyeri* are obviously closely related. Eventually it may be shown that the two species are better regarded as belonging to the same genus, but in the meantime there are no grounds for dissenting from Brinkmann's acceptance of two separate genera, a conclusion based on a thorough comparative review of six species of *Calicotyle*[6] and of *Dictyocotyle coeliaca*[7].

There is nothing in the recent observations by Dawes and Griffiths that would be inconsistent with their having found parts of damaged but otherwise normal specimens of *Calicotyle kroyeri* in the cloacas and abdominal canal of Plymouth hosts which they identified as *Raia radiata*. (The species of *Raia* at Plymouth have been studied in detail[8,9], but *R. radiata* had never been recorded previously.)

IN giving our opinion that '*Dictyocotyle*' is simply a cœlomic form of *Calicotyle* we were well aware of some apparent structural differences between the two forms. Indeed, some of the supposedly distinctive characters had been detailed[1,2]. Perhaps the most obvious difference is one of size ; *Calicotyle* rarely exceeds 5 mm. in length, but '*Dictyocotyle*' may exceed 11 mm. It is not surprising, therefore, that the eggs of the cœlomic form should also be larger. However, the difference is not great, even in the imperfect state of our knowledge. One of us gave the size of the egg of the cœlomic form as 186μ × 100μ, with a filament 19μ long[2]; Hunter and Kille[3], who found many eggs but did not give the size-range, provided the figures 215μ × 100μ (+ 50μ for the filament). In the places cited by Llewellyn, for *Calicotyle*, comparative figures are 100μ × 110μ (+ 35μ for the filament)[4] and 100–110μ (+ 100–130μ for the filament)[5]. As regards shape, which defies description and must be greatly influenced by fixation, the eggs of the cœlomic form were said to be "pyriform"[2], "roughly spindle shaped, and triangular in cross section"[3], while those of *Calicotyle* were described as "triangular in optical section"[4], and "tétraédriques" ("deux côtés du tétraèdre sont parcourus par une lame mince formant une carène")[5]. The "three-sided pyramidal" eggs of *C. affinis* measure 145μ × 104μ (+ filament 52μ long) (no range given)[6]. Incidentally, the "carène" mentioned by Euzet is indicated in photographs of the eggs of '*Dictyocotyle*'[3]. Presumably the cœlomic form has a larger egg because of the greater size of the ootype, but we do not believe that significant differences in shape of the internal cavity of this organ, which acts as a mould in which the egg is formed, can be demonstrated for the cœlomic and cloacal forms in preserved whole mounts. As regards the cuticularized penis, the length is difficult to measure and may be less in forms acceptable to all as *C. kroyeri* than in '*Dictyocotyle*', but it definitely is not less in '*C. affinis*', where it likewise consists of three or more large turns of a spiral. Brinkmann[6] is of the opinion that '*C. affinis*' is a valid species (which is not proved beyond dispute) and a parasite of *Chimaera* which may wander from the cloaca into the rectum, but he found it also in the cloaca of *Raia fullonica*, in which location and host he also found *C. kroyeri*.

Differences in the form of the intestine and the position of the vaginal pores may be explained if we recall to mind the extreme mobility of the internal organs of the living trematode. In *Calicotyle* the presence of the opisthaptor and its extrinsic muscles provides a sort of barrier to the backward movement of the viscera. However, if the haptor is lost, such restraint is removed and the viscera will tend to 'flow' freely into a more posterior position. The same result will no doubt occur also in young forms which do not develop a normal *Calicotyle*-type haptor, the backward flow most obviously affecting the vitellaria and their ducts as well as the cæca. The hind ends of the vaginæ would also be drawn back; but their anterior ends, attached at the pores to the integument, would not be affected. The net result would be an apparently new situation of vaginal pores relative to the anterior ends of both vitellaria and cæca.

Llewellyn asks why *Calicotyle*, after producing viable eggs in the cloaca of the host, should migrate to "a new ecological niche" and there produce more eggs. We do not suggest that the trematode 'indulges' itself in any way, but merely that it passes from a precarious location into nearby abdominal canals during the course of its normal movements. Cœlomic forms presumably attain a larger size because of continued growth in a 'safer' location; cloacal forms above a certain size may be swept away, and the reason may include the fact that the opisthaptor becomes progressively relatively smaller with increase in body-size. It might be asked, however, what is the advantage of 'adopting' a habitat which is disadvantageous should the host be a male. Hunter and Kille[3] found large masses of eggs (which "showed no signs of cleavage") in the cœlom of male skates. Although able manually to squeeze eggs through the abdominal pores (the only means of egress), they had to admit "that escape through the abdominal pores is not very efficient and that the female host is mainly responsible for the transmission of the parasite"[3]. They also found eggs in the spiral valve of some of the rays examined, though it was not clear how they had reached this situation "unless they had been ingested by the host". If and when the eggs of '*Dictyocotyle*' are incubated and the emergent larvæ reared, the relationship between this form and *Calicotyle* may be fully elucidated; in the meantime, the cœlomic form remains enigmatical and we see no reason for modifying our previous opinion.

Cover on River Bottoms

IT was stated by Scott[1] that in a given area of river bottom large stones will cover a greater area of bottom than small stones (if it is assumed that all stones are equally spaced and of similar shape). The relationship between the covered bottom and size of stone is not, however, a simple linear one and it seems desirable to demonstrate this relationship.

In Fig. 1 square stones of side A are arranged at equal distances D from each other inside a square of side L, one square of side A being in the bottom left-hand corner of the enclosing square. The quantities D and L are fixed, and A varies. As A increases the sets of parallel uncovered areas will move to the right and upwards until eventually the stone in the bottom left-hand corner fills the area L^2. The bed of the river is taken to mean the continuous substratum on which the stones rest, the river bottom then being regarded as this bed together with the stones and other relatively discontinuous components resting on the bed. The area of the bed L^2 covered with the stones is denoted by C_v, and we wish to describe the behaviour of C_v as A increases.

In general we can write:

$$L = n(A + D) + x,$$

where $0 \leqslant x < A + D$, and n is a positive integer or zero.

If $A \leqslant x < A + D$, it can be seen that:

$$C_v = (n + 1)^2 A^2$$

Now increase A by a small quantity E so that:

$$L = n(A + E + D) + x', \text{ where } A + E \leqslant x'$$

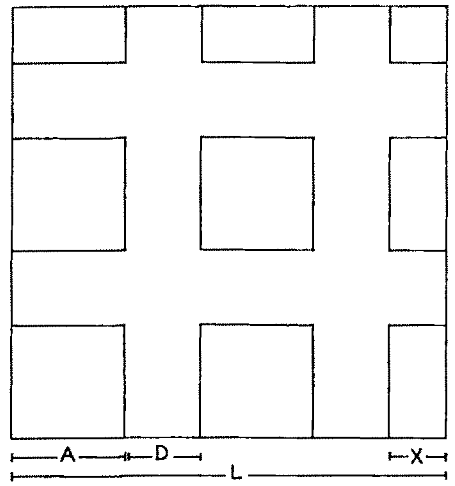

Fig. 1. The case where $0 < x < A$ and $n = 2$

Then:

$$C_v' = (n + 1)^2(A + E)^2$$

and:

$$C_v' - C_v = E(n + 1)^2(2A + E)$$

whence:

$$C_v' > C_v \text{ and so } C_v \text{ increases with } A$$

For $0 < x \leqslant A$, C_v' remains constant as A increases because the increase in C_v due to stones within L^2 is equalled by the decrease in C_v due to stones passing out of L^2. A graph of C_v against A is given in Fig. 2. The increasing portions of the curve are parabolic; but they approximate closely to the straight lines shown. A similar proof for circular stones will be developed elsewhere.

If the above theory is applied to river bottoms certain assumptions and limitations need to be considered. The assumptions of constant A and D are obviously unlikely to be met unless sorting is very efficient. Nevertheless sorting does occur, and it is possible to find areas where constant A and D are approached. It is also possible to create areas of constant A and D experimentally. It is considered, however, that the relationship demonstrated above is of less interest than the concept of C_v as a parameter in river ecology.

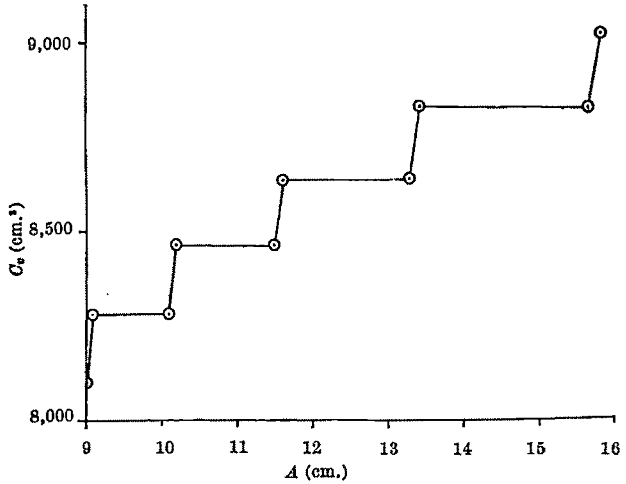

Fig. 2. The relationship between A and C when $L = 100$ cm. and $D = 1$ cm.

The importance of C_v in this respect depends on the fact that a large proportion of the macroscopic invertebrate fauna is found on the ventral faces of stones or on the bed covered by the stones[1-5]. A fraction of the fauna is also associated with the other faces of the stones, but this will not be considered here. The association of much of the fauna with what is here denoted as C_v is probably due to the fact that the stones offer areas in which there is reduced current velocity, protection from vertebrate predators, an accumulation of organic particles, and some degree of stability during floods[1]. It follows that increased size of stone will tend to be correlated with increased population density of the bottom fauna[1,6-9].

The limitations of C_v as a parameter depend on the type of river bottom examined. The usefulness of C_v will vary broadly with the proportion of smaller particles in the bed. A possible limit is offered by the Wentworth scale of clastic sediments, for the upper limit of smaller particles could be taken as 4 mm. (granules), particles below this size being regarded as small in relation to much of the invertebrate fauna. Particles above this size could be regarded as the components providing C_v. Obviously, if the bed were composed largely of boulders, and the interstices were not filled by relatively small particles, the concept of C_v could not readily be applied since cover is offered at layers below the surface of the bed. If, however, the bed consisted of sands and silt most of the fauna would utilize the C_v provided by stones resting on the bed. Another factor affecting the interpretation of C_v is the height of the stones on the bed. With increasing height of these stones, especially where D is small, the ecological difference between C_v and the uncovered bed would tend to lessen, for the screening effect of the stones would tend to bring about in the uncovered areas those factors which characterize C_v.

If these limitations are accepted, C_v can be regarded as a useful parameter. Since it is a measure of several factors that are broadly favourable to river invertebrates, it will tend to be directly related to the population density of the macroscopic bottom fauna. It can be expressed as the ratio of the sum of the areas of the larger stones in a given area to the given area. A sandbank could have $C_v = 0{\cdot}0$, while an area covered with large pieces of bedrock could have $C_v = 0{\cdot}9$.

It is accordingly proposed that the symbol C_v be used in the sense defined above. The letter C is used to denote cover, and since this letter is already used in various ways by limnologists the subscript v is added to denote current velocity.

BACTERIOLOGY

Immunological Activity of Precolostral Calf Serum

A FAILURE of passage of immune and normal antibody across the placenta of the cow has been described by a number of authors[1,2]. Antibodies have been shown to be transferred to the calf, during the first 24 hr., in the colostrum, and this has been shown to be associated with a parallel rise in serum γ-globulin from around 2 per cent of the total serum proteins to 30 per cent, the level found in the adult cow[2].

Sera from 6 calves, taken before suckling could occur, were studied to determine the basic immunological activity of a mammalian serum before the acquisition or development of normal antibodies. The sera were titrated for their bactericidal activity, and estimates were made of the titre of properdin[3] and complement. An attempt was also made to determine whether there was any conglutinin activity in these sera. Titration of bactericidal activity of the fresh sera was performed by Nagington's method[4]. Properdin was titrated by the modified method of Howard, Rowley and Wardlaw[5] and the level of conglutinating complement by that of Hole and Coombs[6].

The serum bactericidal activity of calf *R*80 is shown in Table 1. Similar activity was found with the sera of the other 5 calves. There was little or no bactericidal activity against a wide range of smooth organisms tested, whereas the serum was highly bactericidal against the two rough strains tested, *Salm. typhi SW*540 and *Shig. shiga K*624. This activity was completely removed by absorption with 0·2 gm./ml. of zymosan for 2 hr. at 4° C.

Table 1. MEAN NUMBER OF BACTERIA KILLED BY 0·02 ML. SERUM OF CALF *R*80

Smooth organisms		Rough organisms	
Salm. typhi 0901	< 1·1	*Salm. typhi SW*540	$1 \cdot 2 \times 10^5$
Salm. paratyphi A	< 2·5	*Shig. shiga K*624	$> 7 \cdot 5 \times 10^5$
Shig. shiga	1·3		
Shig. flexner 4	10		
E. coli	< 3·1		
K. pneumoniae	2·0		
Pr. vulgaris	1·4		
Ps. aeruginosa	< 4		
V. el tor	< 1·6		

The bactericidal activity was associated with a level of properdin which ranged within ± 50 per cent of the level found in a normal adult bovine serum, and with conglutinating complement titres of 16–32. No conglutinin was demonstrated by the standard method of Coombs and Coombs[7], but conglutination of starch grains (*Amaranthus cruentus*) and bacteria was observed under the phase-contrast microscope, associated with an inhibition of immune-adherence[8].

The bactericidal activity of precolostral calf serum is probably due to the interaction of properdin and complement. As antibody globulins cannot pass over the placental barrier, it is therefore probable that properdin and the components of complement necessary for the bactericidal activity of precolostral calf serum are developed by the fœtus *in utero* and are not related to the production of normal antibodies which appear to develop as a function of the age of the calf[2].

Precolostral calf serum is an example of the properdin system unaffected by normal antibody. In other systems where the bactericidal activity of properdin has been studied[9], there has always been normal antibody present which might have confused the picture. The experiment described suggests that the properdin system in the new-born calf is relatively inactive against smooth strains of bacteria, whereas it is highly bactericidal to rough strains. This is in keeping with the observation that calves deprived of colostrum are very susceptible to an *E. coli* septicæmia, despite having properdin and complement levels of the same order as those found in adult cattle.

I am indebted to Dr. A. E. Pierce of the Agricultural Research Council Institute of Animal Physiology, Babraham, for providing the six sera, and for checking their electrophoretic composition.

A Source of Error in Microbiological Assays attributable to a Bacterial Inhibitor in Distilled Water

MOST workers in microbiological assay will have had experience of the well-established assay procedure that will occasionally give sub-optimal growth in some of the tubes, and hence discordant replicates. In our experience, folic acid assays using *Streptococcus faecalis* R are particularly prone to troubles of this kind, and such behaviour can be a serious practical difficulty.

We have observed that replication is much better in some batches of 'clean' tubes than in others and that the difference is attributable to an unidentified contaminant in certain batches of distilled water used for the final rinsing of the tubes.

'Difco' folic acid assay medium (single strength) supplemented with 2·5 mμgm. folic acid/ml. was dispensed into 'Pyrex' tubes. After autoclaving and cooling, they were inoculated with one drop of a washed, undiluted suspension of *Streptococcus faecalis* R. cells from a culture 5–8 hr. old, and growth was estimated with a 'Spekker' absorptiometer after overnight incubation. The tubes were cleaned before use by boiling for 10 min. in 2 per cent washing soda, steeping overnight in 3·5 per cent hydrochloric acid, rinsing nine times in tap water and twice in distilled water, and drying in an oven. Such tubes are designated 'clean' tubes. For the work to be described below, 'clean' tubes were filled with distilled water, autoclaved for 15 min. at 15 lb./sq. in. pressure, emptied and dried in an oven immediately before use. Such tubes are designated 'rectified' tubes.

Excellent replication could invariably be obtained if the tubes were 'rectified'; 'clean' tubes, on the other hand, would often give lower and less regular responses. Often this difference would be slight or non-existent, but in extreme instances, some of the 'clean' tubes would show no detectable growth.

Table 1

	Date of washing	3/12	10/12	11/12	17/12	18/12	19/12	20/12	24/12	31/12
'Clean' tubes	No. of tubes	10	12	12	12	12	12	12	10	10
	Mean response	0·264	< 0·109*	0·246	< 0·211*	0·326	0·330	0·458	0·270	0·322
	Coefficient of variation (per cent)	39	>108	35	>60	36	18	11	22	15
'Rectified' tubes	No. of tubes	5	6	6	6	6	6	6	—	4
	Mean response	0·457	0·501	0·497	0·457	0·450	0·450	0·499	—	0·534
	Coefficient of variation (per cent)	2·6	3·0	1·2	6·6	8·2	2·7	1·7	—	1·1

* Some tubes in these series showed negligible growth and were not read.

Batches of 'clean' tubes were compared at intervals over a period of 4 weeks in December 1957 with batches of 'rectified' tubes, and the mean growth responses, together with their coefficients of variation, are summarized in Table 1.

It will be seen that the marked irregularity both within and between batches is markedly reduced by 'rectifying'. It must be emphasized, however, that 'clean' tubes do not always behave as irregularly as in the instances quoted, and some months later, no significant difference could be detected when 'clean' and 'rectified' tubes were compared.

Many attempts were made to vary the details of the glass-washing procedure in the hope of producing the irregular results at will. All were without success until it was found that the important variable is the distilled water used for the final rinsings of the tubes. Some samples of distilled water, it is now clear, contain traces of an inhibitor, and tubes rinsed with it will support only sub-optimal and variable growth. Furthermore, the inhibitor appears to be volatile, for it is lost if the distilled water is degassed by boiling down to 50 per cent of its original volume. Table 2 shows the individual responses, means and coefficients of variation in a typical experiment, and it will be seen that tubes rinsed with degassed water would give results almost as good as those obtained by 'rectifying'.

Table 2

'Rectified' controls	'Clean' tubes			
	Rinsed with untreated distilled water		Rinsed with degassed distilled water	
0·527	0·324	0·028	0·498	0·480
0·504	0·325	0·299	0·504	0·491
0·510	0·351	0·045	0·503	0·484
0·506	0·052	0·281	0·491	0·482
0·529	0·376	0·295	0·478	0·476
Mean 0·515	0·238		0·489	
Coefficient of variation (per cent) 2·3	58		2·0	

Distilled water for glass washing in this laboratory comes from a 'strip action still' which uses steam directly from the steam mains. We have, however, examined samples of water from a 'Bara' still and from an all-glass double-distillation pyrogen-free unit, by using them for the final stages of tube rinsing. Both, on relatively rare occasions, have produced tubes inferior to the 'rectified' controls, and have been shown to be improved by degassing. The contaminant, therefore, is not peculiar to the 'strip action still', and indeed we have encountered periods of many weeks when no advantage was gained by 'rectification' and the inhibitor was, presumably, absent.

So far we have been unable to collect enough material to identify the inhibitor. We have evidence that it may be removed from the distilled water by passing through a mixed bed ion-exchange column or by activated charcoal. It can be removed from the tubes by rinsing with degassed distilled water or even with tap water, but even more successfully by rinsing with ethyl methyl ketone (other solvents have also been used successfully). The pooled ethyl methyl ketone rinsings have been evaporated to small bulk and shown to be markedly inhibitory. A preliminary examination of the residue by infra-red spectroscopy revealed peaks at 2·92, 3·43, 5·87, 7·30 and 7·96μ—a finding not inconsistent with the assumption that the inhibition is probably due to traces of short-chain fatty acids.

Toennies and Gallant[1] mentioned autoclaving in distilled water in the preparation of tubes for *S. faecalis* assays, but they did not speculate on the mechanism of this procedure. Jones[2], quoted by E. M. Lansford (private communication), found that some samples of distilled water would not inactivate biotin, whereas others, containing more than 0·1 p.p.m. of chlorine, would do so completely. Because of this, Lansford[3] degasses his distilled water for the preparation of vitamin supplements. Collier[4] has also shown that 0·3–0·4 p.p.m. chlorine might be present in distilled water. Samples of our distilled water, tested by the *o*-tolidine method, showed less than 0·05 p.p.m. free chlorine.

Wilson[5], as long ago as 1935, found that metal-distilled water had a high, but variable, bactericidal effect which was present at some times but not at others and was apparently due to metallic copper. Rinsing tubes with distilled water containing 100 p.p.m. of added copper sulphate had no effect on our experiments.

Our findings would suggest that traces of volatile inhibitors other than chlorine can occur in distilled water that can be a serious source of frustration in microbiological assays. Not only the tubes may be affected, for we have also found occasional evidence of traces of the inhibitor in other laboratory glassware; batches of medium stored therein give sub-optimal growth. Results to date would seem to indicate that a mixed bed ion-exchange column is effective in the removal of the inhibitor and there may, therefore, be an advantage in using demineralized rather than distilled water for work of this kind, as is recommended by Tomlinson[6] in the preparation of tubes for tissue culture studies.

Some preliminary experiments suggest that modification in methods of culture maintenance and inoculum production in *S. faecalis* assays may influence the sensitivity of the cells to the inhibitor. Clearly, cells that are relatively insensitive to, or media containing an antagonist for, the inhibitor will tend to give more precise assays. Our experiments suggest that *Lactobacillus fermentum* and *L. helveticus* may also be affected to a limited extent, and further experiments on these aspects are in progress.

We are grateful to Dr. E. M. Lansford, jun., for details of results obtained by Miss M. A. Jones at the University of Texas, to Mr. K. J. Stevens, who carried out some of the early experiments in this laboratory, and to Mr. P. R. Watt for examination of our sample with the infra-red spectrophotometer.

Application of Logarithms to the Base 2 in the Use of Exponential Dilution Series for the Study of Antibiotic Combinations

EXPONENTIAL dilution series are useful not only in serology[1,2] but also in the study of the retardation of bacterial growth caused by antibiotics in low concentrations, which may be illustrated by the following example.

Dilution series of antibiotics of concentrations c_0, $c_0.2^{-1}$, $c_0.2^{-2}$.., $c_0.2^{-x}$ are made in a fluid nutrient medium; c_0 is chosen in accordance with the activity of the antibiotic and the sensitivity of the bacterial strain investigated. Growth response after inoculation and incubation may be studied by plotting percentage absorption of light, read at regular time-intervals, against time. A set of growth-curves at more or less regular distances from each other is obtained. Interpolation, however, is difficult. Apparently, the area enclosed by a growth-curve, the time axis and the ordinates of starting- and end-points of incubation would be a good measure for the total growth-response. Having no means for continuous reading of the absorption, we have tried to approximate the response by addition of the absorption read after incubation for 2½, 5, 7½ and 24 hr. respectively. The sum, written Σa, is plotted against x, to give a concentration – response curve. Fig. 1 represents such curves for a strain of *Micrococcus pyogenes* and five antibiotics.

By means of Fig. 1 equivalent antibiotic concentrations can be determined more accurately than hitherto[3]. (We use such concentrations in the sub-bacteriostatic range in the study of antibiotic combinations.) The curves in Fig. 1 show different shapes and slopes. This feature may be difficult to explain, but it is not quite unexpected. For the time, τ, necessary to sterilize a bacterial suspension by an antiseptic, Chick[4] has given the formula $\tau = k.1/c^n$, where c is the concentration, k and n are constants, the latter characteristic of the antibiotic investigated. A similar relation may be expected between concentration and effect of antibiotics in retarding growth, and growth-response would be dependent on concentration in an inverse sense. Whatever may be the exact explanation, the consequence is that the curves in the diagram may cross one another and the ratio of the strengths of two antibiotics may thus depend on concentration. Thus, in our example it can be calculated that at $\Sigma a = 235$, 2^{-4} µgm./ml. erythromycin is equivalent to $2^{-4 \cdot 76}$ µgm./ml. novobiocin, which means that 1·7 µgm. erythromycin equals 1 µgm. novobiocin (the strain is moderately resistant to erythromycin). At $\Sigma a = 105$, however, $2^{-0 \cdot 55}$ µgm./ml. erythromycin is equivalent to 2^{-3} µgm./ml. novobiocin, so here 1 µgm. novobiocin is equalled by 5·5 µgm. erythromycin. The ratio of the relative strengths of erythromycin in both cases is 5·5 : 1·7 = 3·2 : 1. For another strain, having different sensitivities to erythromycin and novobiocin, the corresponding ratio was found to be 2·5 : 1.

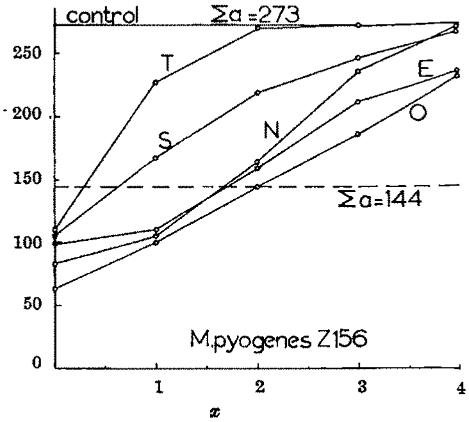

Fig. 1. Concentration–response of *M. pyogenes Z* 156 to five antibiotics. Σa = sum of percentage absorption of light by culture, read after incubation for 2½, 5, 7½ and 24 hr. in 'Bacto' heart infusion broth. Concentration: $c = c_0 \times 2{-}x$; c_x, equivalent concentrations determined for $\Sigma a = 144$.

E, erythromycin; $c_0 = 1$ µgm./ml., $c_x = 1 \times 2^{-1 \cdot 69} = 0 \cdot 31$ µgm./ml.
N, novobiocin; $c_0 = 0 \cdot 25$ µgm./ml., $c_x = 0 \cdot 25 \times 2^{-1 \cdot 66} = 0 \cdot 079$ µgm./ml.
O, oleandomycin; $c_0 = 1$ µgm./ml., $c_x = 1 \times 2^{-2 \cdot 00} = 0 \cdot 25$ µgm./ml.
S, spiramycin; $c_0 = 2$ µgm./ml., $c_x = 2 \times 2^{-0 \cdot 63} = 1 \cdot 30$ µgm./ml.
T, tetracycline; $c_0 = 40$ µgm./ml., $c_x = 40 \times 2^{-0 \cdot 92} = 35$ µgm./ml.

For our purpose concentrations at which the response amounts to about half the control value are most suitable. A reference point is chosen on the curve which best approximates linearity, in our diagram the point $x = 2$, $\Sigma a = 144$ on the curve for oleandomycin. For the other antibiotics, equivalent concentrations can now be found approximately by simple linear interpolation. This can, of course, be done directly from the numbers algebraically, which makes the laborious drawing of the diagram superfluous. The values of c_x in our example have, in fact, been calculated in this way so far as x is concerned. The calculation of $c_0.2^{-x}$ requires logarithms to the base 2. Though a special table may be used, a slide-rule with 'log–log' scales is more convenient. Sufficiently accurate for our purpose is, however, the use of a rule with cubic and $\log_{10}$ scales, since $\sqrt[3]{x}$ on the linear and x on the cubic scale correspond with $0 \cdot 1 \log_2 x$ on the $\log_{10}$ scale, which is proved by the following relation:

$$\log_{10} a = \log_2 a . \log_{10} 2$$

Therefore $\log_{10} \sqrt[3]{x} = \frac{1}{3} \log_{10} x = \frac{1}{3} . \log_{10} 2 . \log_2 x =$

$$\frac{0 \cdot 30103}{3} \log_2 x = 0 \cdot 1 \log_2 x \text{ approximately.}$$

There are no further problems now in the calculation of $c_x = c_0.2^{-x}$, particularly if the slide-rule is also provided with a reciprocal linear scale. Thus, for example, $3{\cdot}2^{-3{\cdot}47} = 3 \times \frac{1}{10{\cdot}35} = 0{\cdot}29$ is calculated in less than a minute.

PSYCHOLOGY

Preferences for Different Combinations of Chance and Skill in Gambling

GAMBLING situations range from those where the outcome is, in fact, more or less beyond the player's control to those where the outcome is more or less within his control in so far as it depends on his skill. In any particular gamble, however, the player's decisions are determined by his view of the situation rather than by its objective features. Thus he may consider the outcome as largely or entirely due to skill when the over-riding factor is chance. Many of the millions who fill in football-pool coupons grossly exaggerate the degree to which skill in completing the coupon can influence their chance of success; and even in a national lottery, such as Premium Bonds in Great Britain, the gambler may persuade himself that he is improving his chances of success by contriving to obtain certain ticket numbers and to avoid others.

Imagine now a range of situations such that, at one extreme, the outcome seems to the player to depend almost entirely on his skill, the element of chance being virtually excluded, and, at the other extreme, the outcome seems to him to depend almost wholly on chance, the element of skill being virtually excluded. The question before us is this: The player is offered the opportunity of choosing one combination of chance and skill on which to gamble, is there a combination which would be generally preferred? We may also ask whether there are individual and group differences in preference due, for example, to age, experience, character, or occupation.

We have carried out experiments in which the basic procedure was as follows. The subject was shown a box containing a varied selection of prizes in the form of sweets and chocolates and he was told he would win one if he succeeded in rolling a ball through an aperture. He stood at one end of a table at the other end of which was a variable aperture which could be adjusted to any width up to 2 ft. At stage 1, the experimenter began to widen the aperture and the subject was asked to stop him when he thought he could get the ball through, say, four times in ten attempts. This procedure was repeated with a second variable aperture, and this time the subject stopped the experimenter when the gap was such that he thought he could get the ball through, say, six times in ten attempts. At stage 2 the subject was told that he could only attempt to roll a ball through an aperture if he succeeded in drawing (blindfolded) a red ball from a bag containing ten balls. If he chose the smaller aperture he would have to draw a ball from a bag containing six red balls in the ten. If he chose the larger aperture he would have to draw a ball from a bag containing four red balls in the ten. The product of the two subjective probabilities, that of drawing a red ball and that of rolling it through the gap, was 0·24 in both instances. In this experiment the subject thus chose between two different combinations of probabilities where the product of the subjective probabilities remained constant.

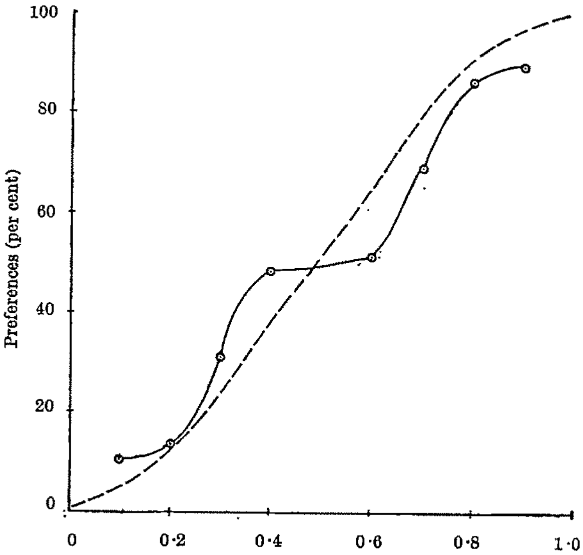

Fig. 1. Preferences plotted against the degree of chance

Four different such choices were presented in random order. In each case the subject had to choose either a larger gap and a smaller proportion of red balls or a smaller gap and a larger proportion of red balls. After the choice in the fourth situation the subject was allowed an attempt to draw a ball which he could aim at the gap and, if successful, win a prize. The four situations and the resulting choices are set out in Table 1. There were 29 male subjects of average age fifteen years.

In Table 1 the value 0·9, for example, under 'skill', means that the subject thought he could roll the ball through a gap nine times out of ten; and the value 0·1, under 'chance', means that there was one red ball in the bag. The preferences are plotted in Fig. 1 against the element of chance in the four situations.

It may be inferred from the figures in Table 1 that whenever a choice has to be made between leaving more to skill or leaving more to chance the subject prefers to rely more on skill, or to leave less to chance, or both. This tendency to rely more on factors within one's control or to rely less on factors outside one's control become more marked as the

Table 1. CHOICES IN SITUATIONS INVOLVING LESS SKILL AND MORE CHANCE OR MORE SKILL AND LESS CHANCE, THE PRODUCT OF THE TWO SUBJECTIVE PROBABILITIES REMAINING CONSTANT (PERCENTAGES)

Alternatives Skill – Chance *or* Skill – Chance (*a*)		(*b*)		Choices (*a*)	(*b*)	Total

0·7	0·3	0·3	0·7	31·0	69·0	100·0
0·6	0·4	0·4	0·6	48·2	51·8	100·0

Table 2. PREFERENCES FOR A PARTICULAR COMBINATION OF SKILL AND CHANCE OUT OF SIX POSSIBLE COMBINATIONS, *A* TO *F*, WITH THE SAME COMPOUND PROBABILITY (PERCENTAGES)

	Skill	Chance	Preferences		
			Grammar school boys	Training college students	Combined groups
A	0·167	1·000	30·9	36·4	34·2
B	0·250	0·667	20·3	15·3	17·3
C	0·333	0·500	34·5	44·1	40·1
D	0·500	0·333	10·7	1·7	5·4
E	0·667	0·250	—	0·8	0·5
F	1·000	0·167	3·6	1·7	2·5
			Total 100·0	100·0	100·0

outcome becomes increasingly dependent on one or other of these two sets of factors.

We still do not know, however, what would be preferred if the subjects were offered a range of such choices in which the total subjective probability remained unchanged. For example, would subjects prefer the combination 0·8 and 0·2 or 0·4 and 0·4? Accordingly, in a second variation of the experimental procedure, other groups of subjects chose one out of six different skill–chance combinations with the same compound probability. In order to be able to offer a wider choice of equivalent compound probabilities, the gap had now to be adjusted to a given number of successes out of a total of twelve attempts and there were twelve balls in the bag. The resulting decisions are shown in Table 2. The sample consisted of 202 subjects, including 84 grammar school boys aged about fifteen years and 118 training college students, male and female, ranging in age from eighteen to forty years.

From the figures in Table 2, together with the reasons given by the subjects for their choice, certain distinctive preferences are evident. First, the vast majority prefer to rely more on their skill than on chance. Secondly, rather more than a third of the subjects prefer to eliminate one source of uncertainty. In most instances (those who chose *A*) the subjects prefer to rule out the possibility of not drawing a red ball; in other words they are anxious to be certain of an attempt to roll a ball through the gap. Thirdly, there is a considerable proportion for whom *C* is the most popular, that is, the situation when there is an even chance of drawing a red ball. This feature is repeatedly emphasized in the subjects' reports. Among the sub-groups of which the grammar school boys were composed, 50 per cent (14 out of 27) of those specializing in classics preferred *C* as compared with only 20 per cent (7 out of 35) of those specializing in science and mathematics. On the other hand, only a small proportion of subjects chose *D*, although here there is a subjective probability of 0·5 of rolling the ball through the gap. It would seem then that, in this situation, a subjective probability of 0·5 which relates to chance impresses the subject more than a value of 0·5 which relates to his skill.

Whatever preferences are expressed in these gambling situations depend on the way the subjects entertain their uncertainties relating to skill and chance. In previous studies[1] we have attempted to elucidate the conditions under which uncertainties from different sources are combined. In the present report we have identified the combinations which are preferred when the product of the subjective probabilities remains constant and we have described the characteristic features in a gambling situation which determine these preferences.

A Priori Probabilities in Gambling

WHEN persons observe randomly generated events of different kinds and are afterwards required to report on the frequency with which each kind of event occurred, they tend to over-estimate the frequency of occurrence of infrequent events and under-estimate that of comparatively frequent ones[1,2].

When persons are offered a choice of bets in a gambling situation they tend to over-value bets involving a low probability of a high gain and under-value bets involving a relatively high probability and low gain. This is true both of behaviour observed in the psychological laboratory[3] and that observed at race meetings[4]. It has been suggested that this is due to an over-estimation of low probabilities and an under-estimation of high ones[3]. This would be in accord with the observations quoted above. But such a simple analysis of the gambling behaviour has been challenged[5] on the grounds that a subjective scale of values for the stakes and prizes which did not correspond to the objective monetary scale (for example, one in which a prize of five pounds was worth more than twenty times a stake of five shillings) could also account for these findings.

I have attempted to examine the question of *a priori* probabilities directly by using a laboratory gambling task and questioning subjects before they begin to play.

In my first experiment subjects had a choice of three bets. One bet had long odds ($P = 0{\cdot}2$), one medium ($P = 0{\cdot}5$), and one short ($P = 0{\cdot}8$). Subjects made repeated choices and played for points. Two pay-off matrices were used. With one matrix, the bet having long odds paid off best (expectancy $+ 1$ point per trial), the middle bet had zero expectancy and the bet with short odds was worst with an expectancy of $- 1$ point per trial. With the other matrix the expectancies were reversed (this was achieved by adjusting the size of the prize available for winning and the penalty extracted for losing). 64 subjects were given one matrix, and a second group of 64 the other. The results showed that the worst bet was chosen more frequently when it had long odds than when it had short odds. Thus this task evoked the same kind of behaviour as that described above.

Only one pay-off matrix was used with my second experiment, the one in which it paid to avoid the bet with long odds. 142 fresh subjects were used. Before they began they completed a questionnaire on which they had to state: (1) the number of times a mathematician would say that each bet would pay off if each was played 100 times (it was stressed that a calculation was expected here); (2) the number of times they would actually expect each bet to pay off. The second statement represents their subjective probabilities.

Eleven subjects failed to make correct calculations of the objective probabilities. The statements of subjective probability made by the remaining

Table 1

Objective probability	Long odds $P = 0{\cdot}2$	$P = 0{\cdot}5$	Short odds $P = 0{\cdot}8$
No. of subjects over-estimating	16	23	62
No. of neutral subjects	30	76	33
No. of subjects under-estimating	85	32	36

subjects have been reduced to three categories: over-estimation, neutrality, and under-estimation. They are shown in Table 1.

This shows clearly that the general tendency is to under-estimate the low probability and over-estimate the high one.

The subjects' subsequent behaviour showed some accordance with their subjective probabilities, but the relationship was not simple. In the first ten choices those who over-estimated the probability of the bet with long odds chose it on average 2·75 times, those who under-estimated 1·32 times, and those who were neutral 0·50 times. There are reasons for believing that the neutral subjects were relatively sophisticated: after the subjective probability statements were given, but before the first choice was made, subjects answered questions about the relative merits of the three bets. 21 of the 30 neutral subjects were able to state correctly which bet would pay off best, whereas only 42 of the 85 under-estimators and 5 of the 16 over-estimators did so.

Finally, although there is this correspondence between subjective probability estimates and subsequent choice of bet, it must be noted that within the group as a whole most choices of the worst bet were made by those who under-estimated the probability of its paying off.

ANTHROPOLOGY and ARCHÆOLOGY

Blood-group Investigation on Central Kalahari Bushmen

During August–September 1958, an expedition organized by the Kalahari Committee of the University of the Witwatersrand (in which the Anthropology Laboratory of the Department of Human Anatomy, Oxford, participated) carried out anthropological, medical, dental and other investigations on Bushmen in the Central Kalahari. The anthropological interest of this study lies in the following: (*a*) two communities examined, some 70 miles south of Ghanzi, were living a primitive hunting and food-gathering existence and could be compared with a third group of Bushmen living on farms in the Ghanzi district; (*b*) the blood of Bushmen from the Kalahari region has not previously been grouped; hitherto all such data have been obtained from Bushmen of South-West Africa; (*c*) the antigens tested included the recently discovered Diego (the serum was kindly supplied by Dr. Layrisse) and also V and Js (sera kindly supplied by Dr. Eloise Giblett). Tests with anti-Diego sera were particularly apposite since some anthropologists have considered it possible that the Bushmen (and Hottentots), on account of their skin colour and frequent possession of an internal epicanthic fold, incorporate a Mongoloid component of distant or even recent derivation. There also is still uncertainty on the exact affinity of the Bushmen to existing Negroid populations. The V and Js antigens are common in Negro populations and therefore supplement information on Negro affinities afforded by other blood-group systems.

The results are given briefly in Table 1 (for unrelated individuals) and will be considered in greater detail elsewhere, along with other genetic evidence obtained from a study of hæmoglobins, haptoglobins and skin colour.

The results indicate that the Central Kalahari Bushmen, like those from South-West Africa, exhibit in general a Negroid pattern in their blood groups, a conclusion already reached by Zoutendyk *et al.*[1]. This is evidenced in the present results by the high frequency of ccDee, along with ccDE in a low frequency and the moderately high CcDe; it is supported also by the ratio of A_2 to A_1, and especially the occurrence of V and Js. For the latter antigens the evidence so far is that a like frequency occurs among the Bantu. The total absence of the Diego antigen recalls a like finding in several Negro populations[2]. It also provides some evidence against mongoloid admixture, as do the low B and the African Rh pattern. The ABO data for these Kalahari Bushmen agree fairly closely with previous results from South-West Africa[3]. The Bushmen, as a whole, as contrasted to Bantu and Negroids generally, are somewhat distinctive in the combination of a high A and a low B frequency and in the complete absence of Rh-negative individuals. It is not likely that there is much admixture in these Bushmen by local Kalahari Bantu since the B frequency is exceptionally low, the O frequency rather high and cde totally absent.

It is difficult from these and previous results to avoid the conclusion that the Bushmen are essentially Negroid, though they have undoubtedly undergone substantial modification, as suggested by various features of their morphology and by their genetic

Table 1. Blood Group Frequencies (Phenotype Percentages) of Central Kalahari Bushmen

constitution as revealed by blood-group studies. Judging by skeletal finds, the Bushmen may well have enjoyed a long period of isolation in the southern tip of the South African continent; such isolation, as well perhaps as the selection resulting from their more recent restriction to the inhospitable parts of South Africa, would seem to be the likely agencies bringing about their differentiation from some older Negroid stock.

We acknowledge gratefully help received from Dr. A. E. Mourant and Dr. B. Kaminer. The work was supported by a grant to one of us (J. S. W.) from the Wenner-Gren Foundation for Anthropological Research.

An 'Australopithecine' Scoop from Herefordshire

Shortly before Christmas last year, I was demonstrating a series of curious scoop-like cannon-bones recovered from the Makapansgat grey breccia during the past year to a group of visitors to show what looked like digging tools when one of the party, Mr. J. W. F. Hampton, said laughingly: "or apple-corers".

On inquiry, I learned that he had suddenly recollected the object in the accompanying photograph around which four of its primeval relatives from Makapansgat are grouped. It was made about 1890 by his father, F. H. F. Hampton from the cannon-bone of a sheep.

The elder Hampton then lived at Ledbury in Herefordshire but fortunately he brought the apple-corer to South Africa with him in 1926, and to his son it had been a diverting mantelpiece ornament. These sheep cannon-bone scoops were still in general use in the early part of the present century in Herefordshire.

They were made chiefly for elderly folk, who loved crisp apples but had lost their teeth, to core their fruit, scoop out the flesh and convey it to their mouths in the form of a pulp. The custom died with the advent of false dentures, a decease doubtless expedited by its cheap metallic replacements in modern chain stores.

The scoop on its left shows the ancestral form from Makapansgat; the cannon-bone on its right with the depressed fracture running along its posterior aspect illustrates the original mode of manufacture, which will be discussed in more detail elsewhere. All that need be said here is that, as no stone tools whatever have been found during the development of seven tons or more of this grey breccia, the fracturing was done by the calculated and repeated impact of bone upon bone.

The two specimens in the top row are included to show that these scoops were made in different sizes and were used right down to the base, even the articular surfaces becoming worn by the severe attrition to which they were subjected.

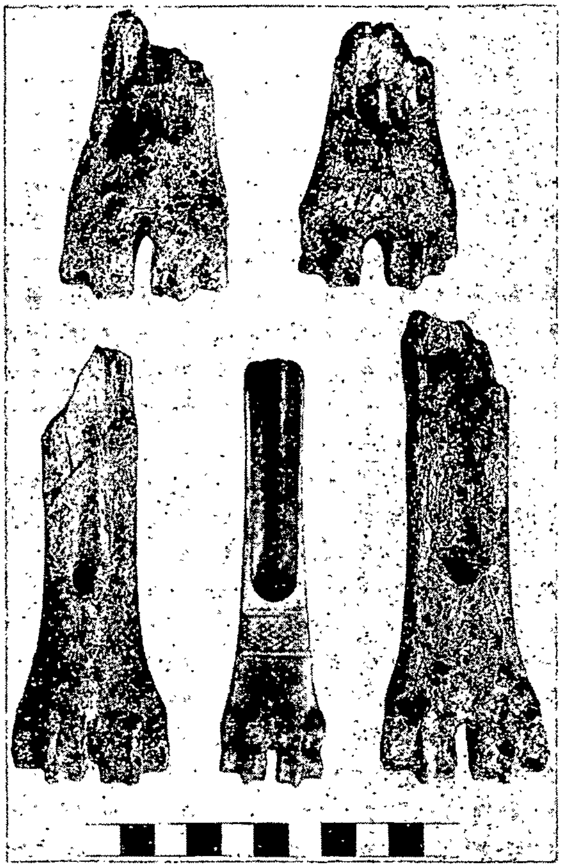

Fig. 1. Four antelope cannon-bone scoops from the australopithecine grey breccia at Makapansgat Limeworks grouped around the central Late Victorian sheep cannon-bone apple-corer made by Mr. F. H. F. Hampton of Rustenburg in the Transvaal about 1890 and resident in Ledbury, Herefordshire, until going to South Africa in 1926. The scoop on its left shows the directness of the comparison to be drawn between the ancestral australopithecine scoop and its recent British counterpart. The scoop on its right illustrates the australopithecine mode of manufacture by percussional linear fracture of the posterior wall of the bone. The two specimens in the upper row are larger forms of the fossil scoop worn down almost to their base by use. (Centimetre scale)

Some of them are so smooth that they look as though they had been oiled and polished; but this unexpected evidence from Herefordshire makes the conclusion inevitable that their state is probably due to their service as scoopers of flesh, fat and other fluid pulps and as conveyors of them to the mouths of toothless infant and aged australopithecines.

I am indebted to the generosity of the Hampton family for permitting me to photograph this fortunately preserved relic, and for their unexpected contribution to the resolution of a problem that has mystified me for the past year. The conservatism of mankind as well as the inventive genius of *Australopithecus prometheus* has been illustrated here by a utensil that seems to have had the lengthiest run of any contrived by human intelligence.

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Mathematical Physicists (with a first- or second-class honours degree in mathematics or physics), to join a section concerned with the assessment of criticality hazards in the handling and processing of fissile materials and to carry out theoretical research into the factors governing criticality and the effects of supercriticality—The Recruitment Officer, United Kingdom Atomic Energy Authority, Industrial Group Headquarters, Risley, Warrington, Lancashire, quoting Ref. 2974/J.14 (March 30).

Associate Professors in Ballistics (Department of Mathematics and Physics); Applied Chemistry (Department of Chemistry and Metallurgy); Mechanics (Department of Civil and Mechanical Engineering); and Radar and Telecommunications (Department of Electrical and Instrument Technology) at the Royal Military College of Science, Shrivenham, Berks—The Civil Service Commission, 17 North Audley Street, London, W.1, quoting S.4949/59/9 (March 31).

Lecturers or Senior Lecturers (according to age, qualifications and experience) at the Royal Military College of Science, Shrivenham, Berks, to teach at University level in Mathematics (two posts); Physics (one post); Civil Engineering (two posts); Surveying (one post—Senior Lecturer); Mechanical Engineering (two posts); Radar and Telecommunications or Engineering Physics or Electrical Engineering (five posts)—The Civil Service Commission, 17 North Audley Street, London, W.1, quoting S.4947/59/8 (March 31).

Assistant Lecturer in Biochemistry in the Rheumatism Research Centre—The Registrar, The University, Manchester 13 (April 4).

Lecturer in Radiochemistry in the Department of Chemistry of the Faculty of Science—The Registrar, The University, Manchester 13 (April 4).

Lecturer in the Department of Physics—The Registrar, University College of Wales, Aberystwyth (April 4).

Senior Lecturer (with research experience, and preferably industrial experience) in Ceramic Materials—The Secretary-Treasurer, Royal College of Science and Technology, Glasgow (April 4).

Assistant Lecturer (Grade III) or Demonstrator in Chemical Physiology—The Registrar and Secretary, The University, Bristol (April 8).

Research Biochemist (honours graduate, with postgraduate research experience in the analytical and metabolic aspects of biochemistry, especially in the field of nitrogen metabolism) in the Fodder Conservation Section, Commonwealth Scientific and Industrial Research Organization, Australia—Mr. E. J. Drake, Chief Scientific Liaison Officer, Africa House, Kingsway, London, W.C.2, quoting Appointment No. 400/75 (April 11).

Assistant Lecturer, Grade B (with good academic qualifications), in Zoology—The Clerk to the Governors, Chelsea College of Science and Technology, Manresa Road, London, S.W.3 (April 13).

Senior Lecturer/Lecturer in Physical Chemistry at the University of New South Wales, Australia—The Agent-General for New South Wales, 56–57 Strand, London, W.C.2 (Australia, April 14).

Lecturers in Experimental and Theoretical Physics—The Secretary of University Court, The University, Glasgow (April 15).

Professor of Applied Physics—The Registrar, University Office, 46 North Bailey, Durham (April 16).

Lecturer in the Department of Metallurgy, to teach and carry out research in Physical Metallurgy—The Registrar, The University, Liverpool (April 18).

Lecturers (2) (qualified in either pure or applied mathematics) in Mathematics—The Secretary of University Court, The University, Glasgow (April 18).

Post-doctoral Research Fellow in the Department of Fuel Technology and Chemical Engineering, to direct and carry out research on the laws of smoke formation and elimination with all types of fuel—The Registrar, The University, Sheffield (April 18).

Research Fellow in Mathematics, an Assistant in Mathematics, and an Assistant in Statistics—The Secretary of University Court, The University, Glasgow (April 18).

Lecturer (graduate, with postgraduate training in animal nutrition) in Animal Husbandry at the University of Sydney, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, April 20).

Lecturer in Geology—The Secretary of University Court, The University, Glasgow (April 20).

Senior Lecturer or Lecturer in Zoology at the University of Khartoum—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (April 23).

Research Officer (Physicist) (with a first- or second-class honours degree in physics, or equivalent qualifications, postgraduate experience in radiation counter techniques, and thoroughly conversant with the physics and construction of ionization chambers, proportional counters, scintillation counters, etc.) in the Technical Physics Section, Australian Atomic Energy Commission, to conduct research into radiation detection techniques and also to develop specialized nuclear particle detectors—A.A.E.C. Liaison Officer, Australia House, Strand, London, W.C.2, quoting "Position R.73" (April 24).

Senior Research Officer (with a degree in medicine and research experience in some branch of medicine or biology); and a Research Officer (with a degree in medicine or science and experience in either biophysics, biochemistry or tissue culture work) in the Section of Biology and Medicine, Australian Atomic Energy Commission, for duties which will include work on acute radiation effects and the cellular effects of radiation—A.A.E.C., Liaison Officer, Australia House, Strand, London, W.C.2 (April 24).

Hives Chair of Thermodynamics—The Registrar, The University, Nottingham (April 30).

Imperial Chemical Industries Research Fellows in Biochemistry, Chemistry, Chemotherapy, Engineering, Metallurgy, Pharmacology or Physics—The Academic Registrar, University of London, Senate House, London, W.C.1 (April 30).

National Coal Board Postdoctoral Fellow in Physical Chemistry, for research work in connexion with the study of solids by a number of techniques such as mass spectroscopy—The Deputy Registrar, The University, Edgbaston, Birmingham 15 (April 30).

Professor of Applied Mathematics at the University of Queensland, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1, or The Registrar, University of Queensland, Brisbane, Australia (April 30).

Turner and Newall Research Fellow in Engineering, Inorganic Chemistry or Physics—The Academic Registrar, University of London, Senate House, London, W.C.1 (April 30).

Assistant Lecturer in Chemistry in the Department of Physiology—The Secretary, Royal Veterinary College (University of London), Royal College Street, London, N.W.1.

Entomologist (B.Sc. biology with specialization in entomology) in the Ministry of Health, Government of the Northern Region of Nigeria, to work on control of *Simulium damnosum*, the vector fly of onchocerciasis—The Director of Recruitment, Colonial Office, London, S.W.1, quoting BCD.117/408/027.

Head (graduate with extensive experience of British agricultural crops and experimentation) of the Trials Branch—The Secretary, National Institute of Agricultural Botany, Huntingdon Road, Cambridge.

Head of the Physics Department—The Headmaster, Campbell College, Belfast.

Master to teach Physics to A level and Mathematics to O level—The Headmaster, King's School, Rochester.

REPORTS and other PUBLICATIONS

(not included in the monthly Books Supplement)

Great Britain and Ireland

Sheffield City Museum. Annual Report for the year ending 31st March 1958. Pp. 22+4 plates. (Sheffield: The City Museum 1958.) [191

This is Apartheid. By Leslie Rubin. Pp. 16. (London: Victor Gollancz, Ltd., 1959.) 1*s.* [191

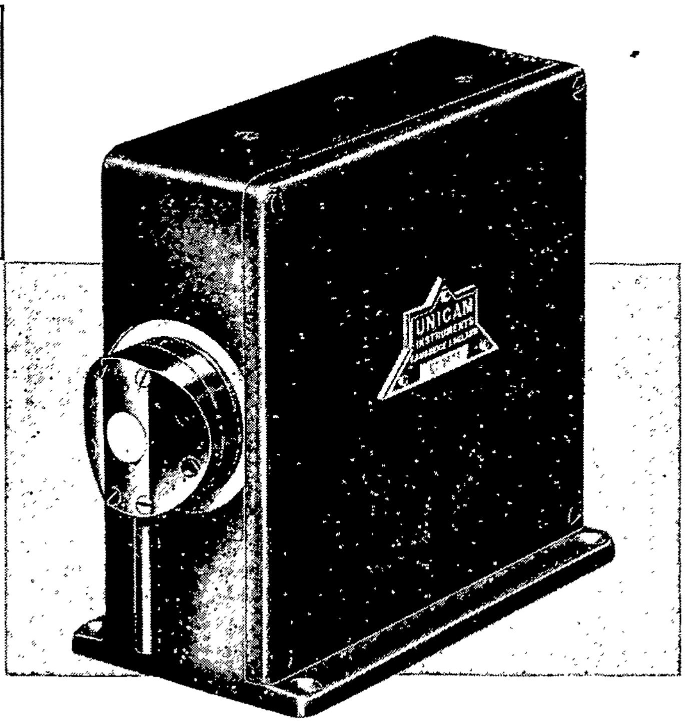
An
INFRARED DETECTOR



sensitive
from
Visible
to
Microwaves

The operation of the Golay Detector is based upon the expansion of a gas of low thermal conductivity in contact with a non-selective heat absorbing membrane. The cell in which the gas (normally Xenon) is sealed has at one end a mirror membrane operating in a photoelectric amplifier system in such a way that the light intensity at the photocell varies directly with the gas expansion.

One of the major advantages of this system is a uniform sensitivity over a wide range of wavelengths. With suitable window material the Detector can be used to measure radiation intensities from visible light out to the microwave region. The adjoining table shows recommended window materials for specific wavelength regions.

The Detector can be delivered from stock with the following windows — KBr, Quartz, KRS-5, CsBr.

We shall be pleased to quote for alternative windows, for the Detector alone or for the full equipment including electronic and chopper units.

TABLE OF WINDOW MATERIALS

Material	Approximate useful wavelength limits
KBr	from visible to 26 μ — 27 μ.
CsBr	,, ,, ,, 35 μ — 40 μ.
CsI	,, ,, ,, 45 μ — 50 μ.
Quartz (0.25 mm thick)	,, ,, ,, 3.5 μ and from 45-50 μ to microwaves.
*Arsenic trisulphide	,, ,, ,, 10 μ.
*KRS-5	,, ,, ,, 35 μ.

*These two salts are non-hygroscopic but introduce some energy losses.

SCIENTIFIC AND TECHNOLOGICAL RESEARCH IN BRITAIN

IN its tenth annual report, the Advisory Council on Scientific Policy published estimates of the national expenditure in Britain on research and development in 1955–56, and of the man-power engaged in that effort, supplementing those given in the report "Scientific and Engineering Man-power in Great Britain" which was issued in the previous autumn. These estimates were based, so far as private industry was concerned, on the preliminary results of an inquiry conducted by Mr. E. Rudd, of the Department of Scientific and Industrial Research, to discover the cost of scientific research and technical development carried out by private manufacturing industry in Great Britain in 1955. The final results of this inquiry have now been presented in a White Paper* issued by the Department and setting forth the considered views of the Economics Committee of the Council for Scientific and Industrial Research. The chairman of that Committee, Prof. E. A. C. Robinson, contributes a foreword.

Prof. Robinson stresses three points. The figures are believed to give as reliable an indication of the scale and distribution of research expenditure in the main sectors of manufacturing industry in Britain as is possible to obtain in present circumstances; but the Committee is aware that estimates of research and development expenditure for individual industries more narrowly defined are subject to margins of error which increase with the extent of the subdivision. Secondly, considerable caution is necessary in reaching conclusions as to the adequacy or inadequacy of research in any particular industry. Frequently the research expenditure of an operating industry considerably under-estimates the volume of relevant research. Thirdly, research and development do not represent the only means by which science can be applied to industry, nor are the limits either of research or development easily and clearly definable. The application of science to industry occurs in departments concerned with design and the improvement of production, as well as in the research and development departments.

The man-power inquiry, carried out by the Social Survey on behalf both of the Department of Scientific and Industrial Research and the Ministry of Labour and National Service, sought information from all manufacturing establishments employing 500 workers or more, and from a sample of those employing between 100 and 499. The second part of the inquiry, which sought to relate man-power with expenditure, collected information from some 238 firms, and more detailed information was obtained from another 94 firms. All these firms volunteered the information, but although the industrial coverage was incomplete and the firms were not a statistical sample, it is believed that the average cost of £1,300 per person employed on research and development in private industry is reasonably accurate. When used, however, to estimate expenditure on research and development in all manufacturing industry, except aircraft, this figure probably leads to under-estimation rather than to over-estimation.

Under research and development, those replying to the questionnaires were asked to include basic and fundamental scientific research and also applied research, technical development and technical service work, including technical design work, done in connexion with different raw materials, or in introducing new working methods. Manufacturers were asked to include prototype production, but to exclude routine analyses, inspection, production, testing and quality control; detailed design of manufacturing units based on information supplied by research; tooling-up and similar preparation for full-scale production, after the development of new plant; and normal production for sale, market research and the selling of an established product.

The survey indicated that in 1955, 109,500 full-time workers were employed in Great Britain by private manufacturing industry on scientific research and technical development at a total cost of £183 million. Since manufacturing industry contributed £6,535 million to the gross national product, expenditure on research and development represented 2·8 per cent of this contribution; but nearly 44 per cent of this research development expenditure is accounted for by the aircraft industry, and this £80 million came largely from Government defence contracts. According to estimates of the Advisory Council on Scientific Policy, defence contracts contributed £118·4 million to research and development in private industry, and on that basis industry's own expenditure on research and development was less than 1 per cent of its contribution to the gross national product. Metal manufacturing and the engineering industries, including vehicles and aircraft, accounted for 77 per cent of the total expenditure on research and development, and the chemical industry, including mineral oil refining, for another 13 per cent.

According to the man-power survey, some 130,000 people are engaged on research and development in private manufacturing industry in Britain, but of these 37,662 are part-time; 35,215 full-time and 14,767 part-time are engaged in the metal manufacturing and engineering industries and 14,810 full-time and 7,138 part-time in the chemical industries. Of the total, 48,829 qualified engineers and scientists are employed in all manufacturing industries; of these, 14,855 scientists and 14,341 engineers are employed in research and development. engineers predominating in the metal-using industries and scientists in the chemical industries, which employ 5,862, or more than two-fifths, of all the scientists engaged on research and development in manufacturing industry. The textile industries employed 765 scientists and 241 engineers on research and development, largely in the man-made fibre industries. The ratio of supporting staff averaged 1 : 3 for all industry and ranged from 1 : 7·5 for aircraft and 1 : 6 for other vehicles and components to 1 : 1·5 for the chemical industries and metal manufacture and 1 : 1 for food, drink and tobacco.

---

* Department of Scientific and Industrial Research. Estimates of Resources devoted to Scientific and Engineering Research and Development in British Manufacturing Industry, 1955. Pp. 50. (London: H.M. Stationery Office, 1958.) 3s. net.

More than half the research and development workers covered by the survey were employed in 683 establishments employing 1,000 or more workers, and together totalling about 37,000 workers, and this average of 55 research and development workers per establishment compared with an average of five in the smallest establishments included in the survey. Moreover, 80 per cent of research and development workers were employed in the 309 firms with research and development staffs of more than 50, and the 2,031 establishments employing 10 or fewer persons in research and development only employed 8 per cent of the total. Afterwards it was estimated that 58 companies or groups account for about £60 million of the total expenditure on research and development in private industry in Britain.

Research and development expenditure as a percentage of the net output averaged 3·5 for all industries, or 2·0 excluding aircraft, and varied from 35·1 for aircraft, 6·8 for electrical engineering and 4·8 for chemical industries, to 0·2 for wood and cork and 0·1 for clothing. Per person it averaged £30 for all industry (or £17 excluding aircraft) and varied from £354 for aircraft, £70 for chemical industries, £56 for electrical engineering, £21 for precision instruments, jewellery, etc., to £0·3 for clothing. In addition to the £183·2 million spent by industry in its own research and development establishments, another £8·9 million is contributed from the research associations and from research stations of the Department of Scientific and Industrial Research, and in the shipbuilding and marine engineering industry this contribution amounts to 81 per cent of the expenditure on research and development. It exceeds 50 per cent in five other industries: boots and shoes (67); linen, jute, hosiery, knitwear and lace (61); wool and worsted (58); cotton (56); and the manufacture of wood and cork (55). In leather, leather goods and fur, it is 38 per cent, and in ceramics 32 per cent.

These figures obviously bear closely on the position of the research associations and indeed of the research stations of the Department of Scientific and Industrial Research, and will no doubt be carefully weighed by the Council of Scientific and Industrial Research in reaching its decisions as to the future of any particular research association or research station. Moreover, while it is desirable, for example, that a research association should receive the maximum support from the industry it serves, the best means of encouraging such support may well vary from industry to industry and depend considerably on the structure of the industry and the size of its units. The predominance of smaller firms may well make this a matter of considerable difficulty in view of the concentration of existing research activities in the larger firms, and added to this there is a widespread illusion among the smaller firms that the larger firms derive proportionately the greatest benefit from co-operative research.

This is possibly true in so far as a smaller firm employs no one capable of assessing the significance of scientific advance for its own activities, and in this connexion the expansion of Britain's effort in research and development is partly an educational problem depending on the supply of sufficient numbers not merely of well-trained scientists and technologists but also of those capable of appreciating the nature and value of scientific work. It is related to education for management in the broadest sense—to ensuring that those who enter industry are at least able to understand the dependence of industry upon technological advance and to make effective use both of the services of scientists and technologists and the new knowledge which is being placed at their disposal. No conclusions are drawn from the estimates in this White Paper, nor are any recommendations included; but the Council for Scientific and Industrial Research and the Advisory Council for Scientific Policy must clearly proceed with great care at this juncture in determining their policy in regard to the research associations and to the research stations. A false step could do much to jeopardize expansion and an apparent immediate economy might prove to involve much wasted effort and greater expenditure in the long run.

The survey was concerned solely with private industry, and only to this extent touches on the research and development effort of the central Government. Even the adequacy of the industrial effort, however, cannot be assessed realistically without reference to the Government effort and to that of the universities and the independent research institutions. A broadsheet issued by Political and Economic Planning shortly after the White Paper was published (No. 430; January 19, 1959) provides a somewhat wider perspective, although it is limited to a survey of scientific and engineering man-power. This is a revised version of a paper written in 1957 by Mr. R. Fort for the Scientific and Technical Committee set up by the North Atlantic Treaty Organization's Conference of Parliamentarians. Although, like Mr. Rudd's survey, it draws largely on "Scientific and Engineering Man-power in Great Britain", it is supplemented by information obtained from the Office of the Lord President of the Council and, besides summarizing the present position of scientific and engineering man-power in the United Kingdom, it reviews briefly Government policy for increasing such man-power, possible improvements in the use of scientific and engineering man-power, trends in education and the content of education in science and engineering.

The survey of the present man-power situation adds little to that given in the last report of the Advisory Council on Scientific Policy. It points out, however, that if we are to aim at about 20,000 young people a year graduating in pure and applied science by 1970, attention to the number of supporting technicians is imperative. The total number of technicians qualifying in 1957 was about 21,000, and this figure may be expected to increase as firms release more students to attend part-time day classes. It is, however, a long way below the figure of up to five or six for every fully qualified scientist or engineer; Mr. Fort's comment that, as more young people recognize the value of a formal qualification, the output from existing courses may have to be doubled to make sure that the numbers of technicians keep pace with the increasing numbers of qualified scientists and engineers, is more likely to be an under-estimate than an over-estimate.

No fresh suggestions for improvements in using trained scientists and engineers are made in the broadsheet, though a little stress is laid on the possibility of using more women scientists in industry. Mr. Fort points out, however, that there is scope for more men and women with scientific and technological training in responsible administrative and commercial posts, where their better understanding of the fundamental problems of the industry in which they work should contribute to greater efficiency and to higher productivity. This in itself accentuates the need for a higher output of scientists and engineers, and for doing everything possible to ensure that they are not employed on work which could be done just as well by technicians or other less highly qualified people.

As regards trends in education, Mr. Fort notes the high wastage among those leaving secondary technical and modern schools at fifteen or sixteen to enter industry and to attend evening courses leading to technician and craft certificates. Only about one in ten of those who start Ordinary National Certificate courses continue to success in the final examination. The wastage in part-time day courses is less, and the trend is towards increasing release for day courses; but it is estimated that 30,000 additional teachers will be required to provide for the increase in part-time day-release students which will result from the increased post-war birth-rate and the introduction of compulsory day-release. Here, again, Mr. Fort points out that the shortage of science teachers is the most serious aspect of the situation, and in discussing the content of education and the relation between school and university education he notes that perhaps one third of the boys and girls in schools are undecided in their preference of science or the arts.

To increase the supply of scientific man-power, therefore, school curricula should be drawn up so as to encourage pupils to decide to take science, while avoiding over-specialization; and university entrance standards should make it as easy as possible for the schools to strike the balance between giving a broadly based education and encouraging the undecided to take science. More specifically, Mr. Fort notes that many pupils at school seem to be discouraged from taking science by their failure to master enough mathematics, and this failure suggests that the methods of teaching may be faulty. Indeed, the most positive contribution of the broadsheet is perhaps its suggestion that at the heart of the whole problem of expanding scientific and technological man-power is the provision of more science teachers in schools; and that attracting more pupils to take science first in the schools and then in the universities, and improving the teaching of mathematics are probably the two most promising steps for providing more such teachers. The first of these comments strongly underlies Dr. Kenneth Hutton's forthright speech at the North of England Education Conference at Scarborough and the Government's dilatoriness in dealing with the three critical factors on which the improvement of science teaching depends.

These two surveys thus demonstrate how interlocked is the whole question of scientific and technological man-power in Britain and our effort in research and development with education generally. They indicate once again the danger of determining policy in any particular sector without reference to repercussions elsewhere. They do not suggest that the present target for scientific and technological man-power is inadequate, but they throw little light on how the redistribution of present or future effort should be effected. The adequacy or inadequacy of research and development in a particular industry can be assessed only by reference to the organization of that industry and its essential characteristics and to the magnitude of the country's effort in fundamental research and the effectiveness of communications. The survey of industry's own effort needs to be supplemented by a corresponding survey of research and development in Government establishments, and by yet another survey of fundamental and applied research in the universities, colleges of technology and in independent research institutions. Moreover, even when the relative magnitude of the effort in terms both of money and of man-power in these different sectors is known, we need to know more about the efficiency with which it is conducted and the adequacy with which the scientist and technologist is supported with equipment as well as with technicians and craftsmen.

It is now more generally recognized that research in the universities needs much more generous support in these respects, but the distribution of fundamental research as between the universities, the independent research institutions, the research associations and the research stations of the Department of Scientific and Industrial Research deserves much more attention. It cannot wisely be decided without clear conceptions as to the functions of these various institutions and the relation of such research to their other functions. Any changes in the work of the Department of Scientific and Industrial Research should follow and not precede such conceptions. It does not, in fact, appear that the Council is as yet prepared to say how far the Department should engage in pure research even in its own research stations, let alone how far the research associations should conduct such research; yet the answer given to the latter question determines considerably the extent to which industries now served by the grant-aided research associations can be fairly expected to bear the full financial responsibility for the research associations.

Again, even if the Department's responsibilities for research of direct application to industry are determined largely by the extent to which further research is likely to be stimulated in industry, the extent to which the Department's own stations should engage in such research will not easily be decided without considering the further problem of how to allocate available resources effectively in order to meet the demands which team-work and highly expensive equipment now make. The Council, in its first annual report, indicated that these questions were already being considered. Its second report will certainly be awaited with considerable interest and some anxiety; but in the meantime these surveys have done something to clarify the picture, and to indicate the points at which further information on the national effort is needed—and some at which action is urgently required—if only to check existing waste and to increase the effectiveness with which present limited resources in trained man-power or expensive equipment are used. Even while new policies are being devised, much could be done to make far more effective use of present expenditure and resources, given sufficient imagination, co-operation and drive.

THE FATHER OF CHEMISTRY

Robert Boyle and Seventeenth-Century Chemistry
By Prof. Marie Boas. Pp. viii+240. (Cambridge: At the University Press, 1958.) 30*s*. net.

DR. MARIE BOAS, assistant professor of the history of science in the University of California, gives an account of the achievements of seventeenth-century chemistry with Robert Boyle as the central figure. The foundation of his development as a scientist is doubtless his early interest in collecting medical recipes and preparing medicaments. He soon became an ardent experimentalist, using the "Book of Nature" as his teacher. He came to regard chemistry as "highly conducive to the true knowledge of Nature", and to be not only a necessary part but also a respectable and useful part of natural philosophy, able to "contribute to its advance as a whole".

The chemical and physical theories of matter current in Boyle's time did not satisfy him, and he developed a mechanical, corpuscular theory, based on experiment, by which he strove to banish all occult notions from natural philosophy. In "The Sceptical Chymist" he demolished the established theory of elements in its various forms, and ended by being doubtful of the existence of any elements. Dr. Boas points out the great difference between the concept of elements then and now, and stresses its importance for a proper understanding of seventeenth-century chemical theory and Boyle's objections to it. His rejection of the old view of a chemical element paved the way for the concept of simple substances, which led ultimately to the new definition of element. His firm belief in corpuscular philosophy apparently provides the explanation of his belief in transmutation, since he considered the change from one metal to another to involve merely a change in corpuscular structure.

The increase in the number of substances resulting from experimental work inevitably raised the problem of chemical composition. Throughout this period the attempt was made to improve chemical nomenclature, basing it on chemical entities instead of imaginary elements or principles. Chemical reactions presented great difficulty, and only gradually came to be regarded as a combination or an interchange of chemical entities. The method of analysis by fire frequently gave very good results, but difficulties in interpretation arose from the confusion caused by variations in experimental technique, and inaccurate nomenclature. Chemical identification tests were greatly extended in scope by Boyle, who evolved precipitation tests, colour reactions, flame tests, and indicators for alkalis.

At an early date Boyle interested himself in chemical classification. His successful classification of acids, alkalis, and neutral substances killed the acid-alkali theory of matter. He recognized that acids had two parts: one that caused all acids to give a colour change with an indicator; the other that made one acid different from another. He was not so successful in his attempts at nomenclature for salts. Boyle's experiments on air are discussed. He could not "believe that the elastic particles of the air are really chemical entities", and he regarded fire, rather than air, as the chief agent responsible for calcination, and the increase in weight of metals.

Boyle's scientific method and experimental technique are discussed in the final chapter. His writings are prolix and frequently tedious; his method of preserving the records of his work prior to publication was haphazard, if not careless; but in contrast to this his experimental work was carefully conceived, detailed, and properly noted at the time. He was a shrewd observer, and no stranger to the use of quantitative methods, even if he was not as accurate with them as he could have been, and at times failed to interpret the results correctly.

The bibliography adequately covers the subject. The index, too, is adequate, but curiously omits all mention of any of the works of Boyle discussed in the text. For references to Boyle's life the octavo edition of 1744 has been used, and for his works the folio edition of the same year. From the point of view of accessibility the quarto edition of 1772 would perhaps have been a better choice for both purposes. Some of the references to the archives of the Royal Society are confusing because the system of nomenclature used by that body has not been adopted. The following corrections, among others, may be noted: p. 9, Boyle returned to England in mid-1644, not in 1645; p. 11, *Add. MSS* 4316 should be 4314; p. 24, Gerard Boate died in 1650, not 1653; and "Ireland's Naturall History" was published under his name as sole author; p. 30, Boyle was in Ireland by the last week of June 1652; p. 211, the reference should read "Royal Society. Correspondence. Early Letters. Guardbook B.1. 100", and the date of the letter is "9 Dec" not "2 Dec". These, however, are minor errors, and in no way detract from the brilliance of this important book, in which Dr. Boas, with a skilful marshalling of widely distributed facts from Boyle's works and papers, conducts the reader in virtuoso manner through the labyrinth of seventeenth-century chemical thought and practice.

R. E. W. MADDISON

PLASTICS FOR THE PRACTICAL MAN

Polyurethanes

By Bernard A. Dombrow. (Reinhold Plastics Applications Series.) Pp. ix+176. (New York: Reinhold Publishing Corporation; London: Chapman and Hall, Ltd., 1957.) 4.50 dollars.

Polyamide Resins

By Don E. Floyd. (Reinhold Plastics Applications Series.) Pp. viii+230. (New York: Reinhold Publishing Corporation; London: Chapman and Hall, Ltd., 1958.) 4.50 dollars.

Plastic Sheet Forming

By Robert L. Butzko. (Reinhold Plastics Applications Series.) Pp. ix+181. (New York: Reinhold Publishing Corporation; London: Chapman and Hall, Ltd., 1958.) 4.50 dollars.

Cellulosics

By Walter D. Paist. (Reinhold Plastics Applications Series.) Pp. xi+270. (New York: Reinhold Publishing Corporation; London: Chapman and Hall, Ltd., 1958.) 5.75 dollars.

Fluorocarbons

By Merritt Allen Rudner. (Reinhold Plastics Applications Series.) Pp. x+238. (New York: Reinhold Publishing Corporation; London: Chapman and Hall, Ltd., 1958.) 5.75 dollars.

"THE Modern Plastics Encyclopedia" for 1958 lists 102 books on plastics and high polymers published since 1950. To this literature, a new series of monographs has been added (Reinhold Plastics Application Series) of which six have been issued while ten more are in preparation. Their appearance coincides with a recent decision of the Plastics Institute to make its set of eleven titles in the Plastics Monograph series available to the public through an arrangement with Messrs. Iliffe.

Any protest at this profusion of books on plastics must be tempered by the awareness of much disagreement existing between the experts as to the very nature of plastics as displayed at the recent Polymer Tribunal. In any event, any new book may be welcomed if it largely comprises new material or a novel presentation, and it is in this spirit that the present series may be reviewed.

In "Polyurethanes", a brief account of their chemistry is followed by chapters on foams, rubbers and surface-coating and adhesive applications. The book makes clear which are the commercially important raw materials and the manner in which the systems function in diverse applications. It contains a useful account of polyurethanes derived from castor oil, and hindered and reversible systems and, despite the absence of serial references, should have a reasonably wide appeal.

"Polyamide Resins" is written with a chemical slant, and serial references are given to published work. The book contains little that is new about fibre-forming polyamides and may be valued principally for the information it gives on the novel 'Versamid' dimeric fatty acid/polyalkylene amine polyamides and their blends with epoxy resins, with which the author is specially familiar by virtue of his association with General Mills Inc.

The reader of "Plastic Sheet Forming" will be impressed with the scope of this versatile technique by the long list of applications assembled. Nineteen variations of the process illustrated by easy-to-follow diagrams and an account of commercially available equipment, including cost estimates, makes it possible to recommend this as a very useful practical guide to those contemplating the use of the sheet-forming process.

In contrast with the three books listed above, the author of "Cellulosics" has had to deal with a subject in which there is a very considerable literature. The presentation ranges from fabrication techniques for spectacle frames to the dyeing of woven fabrics. In attempting to cover all outlets for cellulose and its derivatives, the book is of proportionately reduced value to the student of plastics. Neither references nor a separate bibliography are given. Table 3.5 requires correction.

The title of "Fluorocarbons" is somewhat misleading, for the book contains no mention of materials other than polymers of tetrafluorethylene and monochloro trifluorethylene. Even on these, there is little information not normally available from sales and technical bulletins. The term molecular weight is often used in the wrong sense, and a chapter on the chemistry of fluorocarbons (written in collaboration with Claude Bunnell) is marred by misprints.

In an ostensibly uniform series of monographs, a bad impression created by any one book tends to prejudice the reader against the remainder of the series. Such a temptation should be resisted and, as this review shows, each monograph should be appraised on its own merits. One overall criticism, which is often made in regard to American publications, is that the price per book will be considered high in Britain in relation to the value. S. H. PINNER

MAMMALIAN HAIR

The Biology of Hair Growth

Edited by William Montagna and Richard A. Ellis. Pp. xvii+520. (New York: Academic Press, Inc.; London: Academic Books, Ltd., 1958.) 15 dollars.

THIS book, equivalent to proceedings of the Conference on Hair Growth held in London in 1957, is a revelation of progress and promise. Those working on hair will need no encouragement to keep this book always at hand. It reports a modern breakthrough, by new techniques and experiment, largely in young branches of old sciences, often concerned with very minute structure and tiny quantities. Hair is very favourable material for relating biochemistry to morphology. Though much remains to be discovered, Montagna may reasonably claim, after surveying recent advances which emphasize how precise is the control of the intense activity of the follicle, that "the understanding of the prime forces that guide and control hair growth cannot be far off".

As an organ, the hair follicle corresponds in convenience with Protozoa among animal types, and examples follow of phenomena and principles of which bio-scientists in other fields may care to take note. Cell division is an all-or-none reaction, and even the death of the animal does not arrest it (Bullough, on mitosis). Some treatments inhibit initiation of growth, but have no effect on follicles already growing (Mohn, and Montagna's summary). An intricate balance of many hormones is required for the normal occurrence of the periodic waves of spontaneous replacement in the rat (Mohn). The response of follicles to treatments depends on the phase of the growth-cycle in rodents, and in man (Van Scott). The presence of growth-waves in the rat, and their absence from the guinea pig, are probably related to vascularization (Durward and Rudall). In fibrogenesis the same end-result is evidently reached by different routes (Mercer). Reduction of the size of the follicle in catagen is retrograde morphogenetic transformation, not degeneration in the usual sense (Montagna and Van Scott). The idea that the cell components may first dissociate and then reunite is a contribution to thought on the mode of working of the gene (Rothman).

Practical application is being sought chiefly in the extremely odd coats of fleece-bearing sheep and man, which both pose fascinating problems in evolution. As to wool, more reciprocal trade is desirable between mouseries and both farms and mills. With reference to human cancer, all that will be said here is that work on the inheritance of coat colour in rodents half a century ago was research now related to human cancer (Fitzpatrick *et al.*, p. 279). A still more widespread killing disability in the human race is maleness. Apparently there is a spectrum in which tendencies to highly developed secondary sex characters merge with tendencies to sex-selective pathological states, rapid aging, and short duration of life (Hamilton, p. 431). Any new fact about hair may save male life and wits.

In gratitude to the late Prof. Walter Garstang this opportunity is taken to report that he coined the terms for growth-phases, anagen, catagen, telogen, and the names of the fibre types monotrich, awl, and auchene, in one short discussion. For the fourth fibre type he then proposed ptychotrich, but a few days later substituted zigzag. F. W. DRY

THEORETICAL PRINCIPLES OF ORGANIC CHEMISTRY

Theoretical Principles of Organic Chemistry

Vol 2. By Prof. Walter Hückel. Translated from the corrected 7th German edition by Prof. F. H. Rathmann. Pp. xi+1046. (Amsterdam: Elsevier Publishing Company; London: D. Van Nostrand Company, Ltd., 1958.) 95*s*.

THIS completes the translation of Prof. Walter Hückel's text-book, the first volume of which was reviewed some three years ago (*Nature*, 176, 991; 1955). It was concerned in part with valency theory and stereochemistry, dealt with under the heading of chemical statics; and in part with structural rearrangement and the chemistry of unsaturated compounds, dealt with under the heading of chemical dynamics.

The present volume deals with constitution as it determines physical properties and reaction velocities. Under the former heading are considered, *inter alia*, thermodynamic, electrical, and optical properties; relations between cohesion and constitution; properties of organic colloids and crystals; and the nature of the chemical bond. Under the latter are considered general theories of reaction velocity, and their applications; particularly to the hydrolysis of esters, to aromatic substitution, to polymerization, and to ring closures. Equilibrium constants for acidic dissociation, for ring closures, and for reversible oxidation-reduction processes are also considered briefly.

This volume, like the first, is well printed and produced. But it is tediously written, it contains many infelicities of translation, and it gives far too much prominence to out-moded and incorrect theories. Its treatment of electrophilic aromatic substitution is particularly confusing and disordered. An attempt is made to contrast the qualitative electronic theory with the quantum-mechanical treatment attributed to Wheland and to Seel. It is stated, for example (p. 800), that the latter theory "makes unnecessary the assumption of postulated hypothetical effects". The reviewer considers that the author has appreciated incompletely not only the part played by factors of polarizability in the former theory but also the extent to which the "hypothetical effects" are concealed in the arbitrary assumptions of the latter. The reader will not be helped by Prof. Hückel's discussion of the former theory through the introduction of a "general effect", which deactivates for electrophilic substitution, but is identified strangely with Wheland's "polarization effect" and with Ingold's "inductometric (*sic*) effect".

Taken as a whole, the reviewer believes that these volumes will not generally be found useful by chemists familiar with other works available in the English language. P. B. D. DE LA MARE

AMERICAN MARINE LIFE

The Underwater Guide to Marine Life

By Carleton Ray and Elgin Ciampi. Pp. xiii+338+16 plates. (London: Nicholas Kaye, Ltd., 1958.) 30*s*. net.

THIS book about life in American coastal waters first appeared in the United States in 1956 and one wonders why an English publisher should have thought it suitable for the English market. Perhaps he is not aware that relatively few of the species described are to be found in European seas and that this book is of very limited interest to skin-divers (for whom it is primarily intended) on the eastern side of the Atlantic. His advertisements, one of them in a popular journal widely read by sub-aqua club members in Britain, certainly do not make any mention of this and in consequence are misleading.

The book, printed in the United States, is beautifully produced and attractively illustrated with many drawings and photographs, in both colour and black and white. It is true that the coloured drawings are sometimes not quite correctly tinted, but they are reasonably accurate in outline and will serve for identification, if not always for the species at least for the group. The preliminary chapters give an elementary account of the environment and of the general biology of the sea. The chapters on the techniques of underwater swimming and photography are too short to be really useful and the space they occupy could, with advantage, have been devoted to expanding the sections on plant life, and on the invertebrates which receive all too brief a treatment. The section on fishes occupies about half the book and is the most valuable portion of it. The final chapter deals briefly with marine reptiles and mammals. Apart from some minor errors of no great significance the book is accurate and well written, and should adequately serve its purpose as an underwater swimmer's guide to life on both coasts of the United States, especially the warmer parts. It should be very useful, too, to anyone visiting the magnificent marine aquaria and oceanaria of that country. D. P. WILSON

THE SOUTH AFRICAN COUNCIL FOR SCIENTIFIC AND INDUSTRIAL RESEARCH

By Dr. S. M. NAUDÉ
President

WHEN he was called upon in 1944 by the Prime Minister of South Africa, the late General Smuts, to draft legislation for the promotion of scientific research in the Union of South Africa, Dr. B. F. J. Schonland had the advantage of being able to study the successes and failures of a number of official research organizations both within the Commonwealth and in other countries, notably the United States. The basic Act under which the South African Council for Scientific and Industrial Research came into being in 1945 thus reflects many of the best features of research bodies in existence at that time. The South African Council for Scientific and Industrial Research has now functioned for some thirteen years, and, looking back, we are in a position to assess the success of that early planning.

One of the most important features insisted upon by Dr. Schonland, who afterwards became the first president of the Council for Scientific and Industrial Research, was that while adequate provision should be made for Parliamentary control, the day-to-day administration should be free of direct control by any Government administrative department. This was achieved by the establishment of a council of nine members (later increased to sixteen) appointed by the Governor-General on the basis of their personal reputation and achievement as leading men of science in the technical departments of the Government service, the universities and industry. The Council is responsible directly to the Minister of Economic Affairs, who in turn answers to Parliament, but the annual budget is subject to Treasury approval. In staff matters the Council is not bound by the regulations of the Public Service Commission, but in practice follows them closely. Over the years the Council has been reasonably successful in retaining its freedom of action, though from time to time it has had to resist pressure from departmental administrators.

Another important feature of the organization of the South African Council for Scientific and Industrial Research is that, as in the case of the Canadian National Research Council, the president is at the same time chairman and chief executive officer. This ensures on one hand that the policy of the Council is carried out expeditiously and, on the other, that no decision is taken without full cognizance of the administrative problems involved. As the Council normally does not meet more than three times a year, routine and urgent matters are dealt with by the president with the assistance of an executive committee the decisions of which are subject to ratification by the full Council. On the administrative side, the president is assisted by two vice-presidents, who attend Council meetings but have no vote. This arrangement places the president in a powerful position; but in practice it has worked extremely well to provide effective and purposeful execution of a policy laid down by the country's leading scientists, industrialists, educationists and technical administrators.

The terms of reference of the South African Council for Scientific and Industrial Research, covering the promotion of scientific research in general, are very wide, but they exclude agricultural research, which is the responsibility of the Department of Agriculture, and research in the social sciences, for which there is a separate council. In practice, demarcation between different fields of research is often artificial, and the Council co-operates closely with these bodies in such fields as industrial psychology and the industrial use of agricultural products which do fall within the Council's sphere of activities. In the absence of a separate body to deal with medical research, this, too, is the Council's responsibility, and, since 1956, it has also been responsible for the statutory functions of the former Standards Council, including the administrative control of the South African Bureau of Standards.

Policy

After detailed study of the conditions existing in the Union of South Africa at the close of the Second World War, the first Council decided that promotion of scientific and industrial research should be along four major lines:

(1) In order to provide the Government and industry with the basic facilities of modern scientific research, it would establish, equip and operate a limited number of national laboratories for both fundamental and applied research.

(2) It would offer inducement to industry to conduct its own research. This would take the form of remission of taxation of research expenditure, direct financial assistance to co-operative industrial research associations and the provision of facilities in its national laboratories for confidential research sponsored by individual firms.

(3) To ensure the rapid utilization of the results of research going on both locally and abroad, it would establish comprehensive liaison and information services, including a central scientific library and overseas offices.

(4) Finally, in order to ensure a steady flow of trained research workers, it would establish a system of postgraduate bursaries and research grants in the universities.

The fact that after some thirteen years of practical experience these still remain the corner-stones of the Council's policy bears testimony to the wisdom of this early planning.

Administration

The running expenses of the Council have risen steadily year by year and at present are of the order

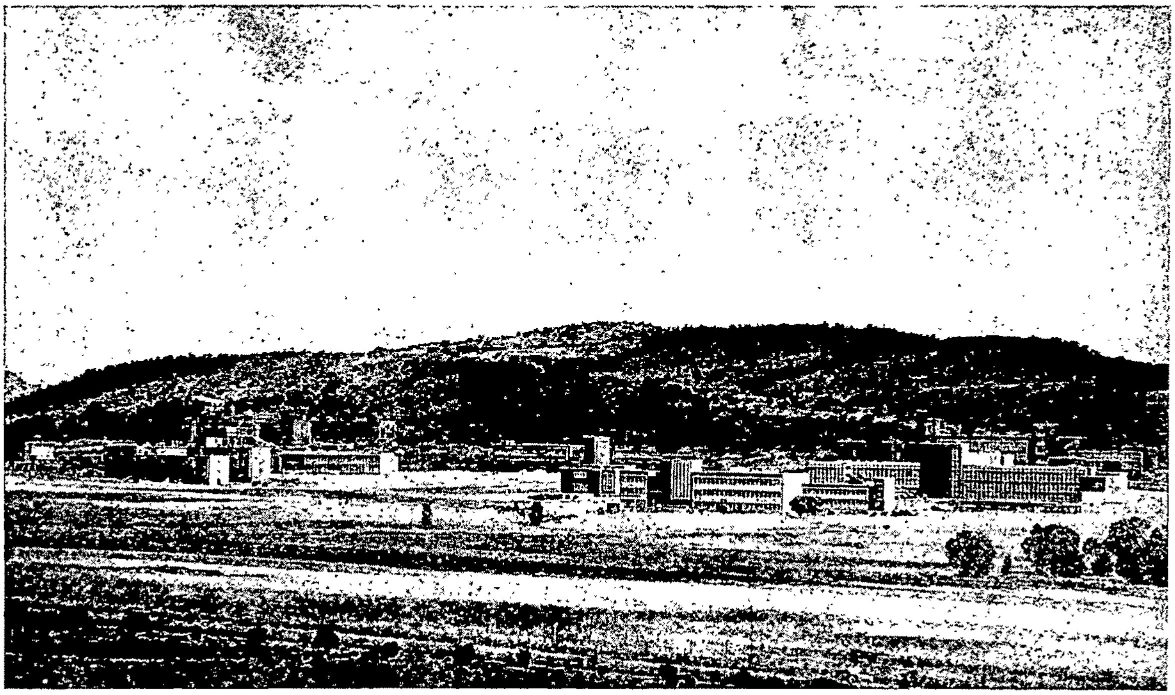

Fig. 1. New buildings at Scientia, the research centre of the South African Council for Scientific and Industrial Research

of £2,450,000 a year. Of this, the Parliamentary grant accounts for approximately £1,760,000, the remainder being earned by way of remuneration for investigations carried out for industry, fees and grants from other sources. The Council's assets in the form of capital equipment amount to a total of about £1,800,000, while the current valuation of its buildings stands at £1,122,000. The latter figure represents approximately one-third of the current building programme which is expected to be completed in the course of the next few years.

At the time of its establishment in 1945, the Council had the greatest difficulty in recruiting trained research workers, for even in the universities little active research was in progress. However, a small nucleus of enthusiastic young scientists was recruited, and several of them were sent for periods of up to two years for specialized training in research institutions in the United Kingdom, the United States and, later, Europe. Around this nucleus it has been possible to build the permanent staff of the Council, which now numbers a little less than 2,000, of whom approximately 550 are graduates. The average age of the staff is thirty-one years, and the number of women members is just short of 25 per cent. It is interesting to note that, although vacancies are widely advertised overseas, it has proved possible to recruit the great majority of scientists in South Africa. Throughout the thirteen years of its existence the total number of research workers recruited overseas has not exceeded fifty.

The recruitment of adequately trained staff, however, still remains one of the principal problems with which the Council has to contend. Apart from the general programmes aimed at increasing the output of research workers from the universities, about which more will be said later, two specific training programmes have been adopted. The first of these, known as the Overseas Directed Research Bursaries Scheme, is aimed at increasing the supply of trained research workers in fields in which the shortage is particularly acute or for which no adequate training facilities exist in South Africa. Under this scheme, young graduates are awarded bursaries of £500–£1,000 per annum plus a travel grant to enable them to study a subject designated by the Council. The bursaries may be renewed from year to year on the recommendation of a referee, usually a senior member of the Council's staff, to whom the bursar is required to report at regular intervals. The bursar must undertake to return to South Africa on completion of his study. The other is an undergraduate scheme whereby promising students are granted bursaries according to their needs to enable them to attend full-time degree courses at a South African university. In return, they are required to sign an undertaking to accept employment with the Council for a number of years, depending on the total amount of the grant.

Standardization

One way in which the South African Council for Scientific and Industrial Research differs from similar organizations in other countries is that it also has responsibilities for the promotion of standardization in industry. Originally this was the responsibility of a separate Standards Council, which also operated extensive laboratories for testing and investigations aimed at the improvement of industrial processes. In 1956, however, it was decided to abolish the Standards Council and transfer its functions to the Council for Scientific and Industrial Research. The reason for the change was that research and standardization may be regarded as complementary means of promoting industrial development, and the work could be most effectively co-ordinated by a single controlling authority.

The existing South African Bureau of Standards was retained as the instrument for giving effect to the Council's policy in regard to standardization and is now operated as one of the national laboratories. The methods whereby standard specifications and codes of practice are drawn up in consultation with manufacturers, consumers, government departments and other interested bodies are similar to those adopted elsewhere, but it is worth mentioning that the work of the committees responsible for drawing up specifications is greatly facilitated by being able to draw on the resources not only of the technical staff of the Bureau but also of the Council's research laboratories.

The adoption of all specifications issued by the Council is entirely voluntary, except where the health or safety of the public is concerned or where gross malpractice is taking place. In such cases the Minister of Economic Affairs may declare a particular specification compulsory.

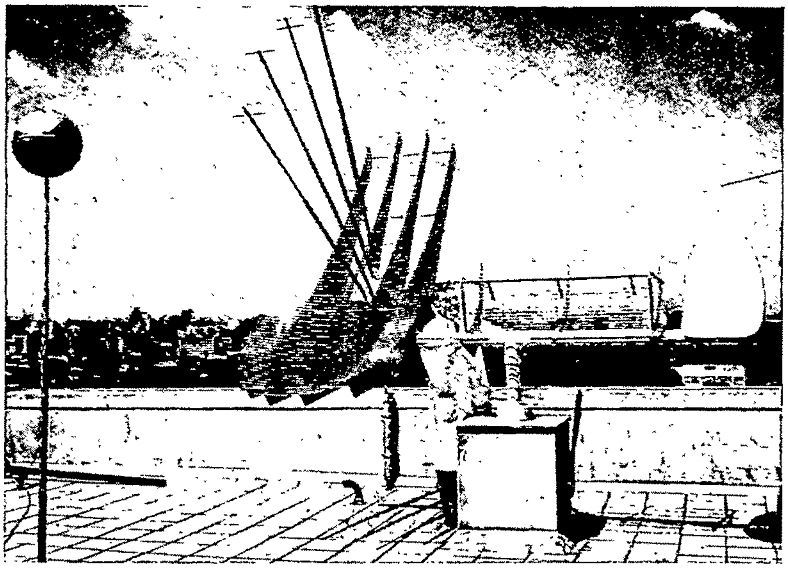

Fig. 2. Antenna display used by the South African National Telecommunications Research Institute in Johannesburg for research into the mechanism of lightning discharges

Linked with the preparation and issue of specifications and codes of practice is the standardization mark scheme, whereby a manufacturer producing articles in accordance with the requirements laid down in the specification may seek permission to apply one of the Bureau's marks to his product. The mark is protected by law, and quality is maintained by a regular system of inspection, sampling and testing in the Bureau's laboratories.

A further important service provided in the standards laboratories is general test work for consumers, public bodies and government departments. Normally, work which can be handled by private consultants and analytical laboratories is not accepted, but tests are undertaken for purposes of arbitration, together with a certain amount of forensic investigation on behalf of the police.

The services which the Bureau of Standards has been able to render industry have played a big part in the industrial development of South Africa. The expansion of our industries has proceeded largely by the introduction of established industrial practices and other adaptations to suit local conditions. Here the Bureau has been able to give a great deal of assistance by means of its testing facilities, by which it has been able not only to help manufacturers to procure raw materials and components against recognized specifications but also it has enabled them to assess the quality of their finished products and to compare them with equivalent products manufactured in other countries.

Research Laboratories

There are nine national research laboratories which conduct broad programmes of research, both fundamental and applied, aimed at providing the scientific information essential to the efficient utilization of the natural resources of South Africa. The National Chemical Research Laboratory, for example, has on its research programme a number of research projects which relate to raw materials or potential raw materials for South African industry. The National Physical Research Laboratory is responsible for maintaining South Africa's basic standards of physical quantities such as the units of measurement, heat, colour, sound and electricity; and is equipped to deal with specialized problems which require the use of physical techniques such as X-ray diffraction, electron microscopy, mass spectrometry and high-energy radiation. The problems involved in overcoming the critical shortage of housing at the end of the Second World War, together with those associated with the massive migration of native labour into urban areas to serve industry, led to the establishment of the National Building Research Institute, while the establishment of a large State-supported National Institute for Personnel Research to conduct research in the field of industrial psychology is a reflexion of South Africa's unique problems of man-power and human relations. This Institute developed out of research undertaken during the War for the Armed Services, as did the National Telecommunications Research Institute, which conducts research into radio propagation problems. Of more recent establishment are the National Institute for Road Research, the National Nutrition Research Institute, the National Mechanical Engineering Research Institute and the National Institute for Water Research.

The programmes of these laboratories are drawn up with the help of advisory committees and project sub-committees which advise the Council on the assignment of priorities. In recent years some of these advisory committees have been replaced by specialist advisers, who periodically investigate and report on the research programmes of sections of the laboratories. This system shows great promise, as it is at once less cumbersome and more effective than the committee system.

In addition to their normal research programme, these national laboratories perform a function similar to that fulfilled in the United States by the independent applied research foundations such as Battelle and the Mellon Institute. They undertake confidential research on a contract or fellowship basis for industrial sponsors, who may be single firms or groups of firms. In recent years this work has assumed considerable importance and provides a substantial proportion of the Council's operating revenue.

In certain instances the research staff are permitted to spend up to 30 per cent of their time on 'personal interest' projects and, as is to be expected, these often result in research of outstanding quality with practical implications which could not be foreseen when the projects were initiated.

Research in Industry

However, it is the policy of the Council to persuade industry to undertake its own research wherever possible. In a relatively newly industrialized country like South Africa, research on a worth-while scale needing elaborate and often expensive equipment and the services of highly trained scientists is generally beyond the means of individual firms; it is therefore essential that research of this kind should be organized on a group basis. To achieve this, the Council adopted a research association scheme similar to that developed by the Department of Scientific and Industrial Research in the United Kingdom.

To date, five associations, covering the leather, paint, fish processing, sugar milling and wool textile industries, have been formed. They are financed by annual subscriptions guaranteed for a minimum period of five years by the majority of firms in the industry concerned, matched by an approximately equal grant from the Council for Scientific and Industrial Research. Industrial contributions not guaranteed for the full period of five years also earn a Council subsidy but on a less generous scale. These industrial research associations are registered under the Companies Act as non-profit companies and are managed by boards of control on which the industrial contributors have majority representation. The research programmes are confined mainly to directed research problems of common interest to member firms, and to the solution of technological problems which arise in the day-to-day operations of individual factories.

An important feature of the research association scheme in South Africa is that all the associations are located at universities, one at the University of Cape Town, two at Rhodes University in Grahamstown, and two at the University of Natal in Durban. The directors have been accorded the status of professor by the universities concerned, and a close and fruitful relationship has resulted. All five associations have now run out of their first or second five-year guarantee periods, and the measure of their success may be judged by the fact that industrial contributions are still increasing both in number and amount.

Information and Liaison Services

Scientists and engineers throughout the world are slowly—perhaps too slowly—coming to realize that progress in science depends upon the intelligent solution of problems in the field of scientific and technical information. These problems are aggravated in a country in which centres of population are separated by great distances and in which there are no great libraries such as in Europe or North America. Whereas in older countries the main problems are concerned with making resources of scientific and technical information available to the users, in South Africa the more immediate need is to build up these resources.

One of the Council's first actions was thus to establish an advanced central scientific library to serve not only its own staff but also research workers throughout South Africa. A feature of this library is a very large collection of pamphlets and reports, each of which is fully 'processed'.

Associated with the library is an information service. This includes a technical and bibliographic inquiry service which is able to draw on the written word and the accumulated experience of scientists and engineers in the Council's laboratories. This is backed up by the Council's scientific liaison services in London, Washington and Cologne, through which the scientist in South Africa can draw on the resources of the great libraries of Europe and North America or get into direct touch with co-workers in other countries. There is a translation service, and other activities include the compilation and publication of the "Catalogue of Union Periodicals" and various scientific directories.

The Council shares with the Department of External Affairs the Government's responsibility for maintaining international relations in science. The Council's scientific liaison officers in London, Washington and Cologne are accorded the status of attachés to the Union's diplomatic missions in their respective areas and, in addition to reporting on the latest developments in the field of science, act as scientific advisers to the heads of the missions concerned. On behalf of South Africa, the Council adheres to the International Union of Scientific Unions and provides the secretariat for the South African national committees of its affiliated unions. It has, for example, been extremely active in organizing South Africa's participation in the International Geophysical Year.

University Research

The Council early realized that, if the new industries which had grown up during the Second World War and the new research organizations which had been established soon after it were to be adequately staffed, it would be necessary to augment the supply of graduates with advanced degrees from the universities. Unfortunately, South African universities have not been generously endowed by private individuals, industrial corporations and benevolent foundations as is often the case overseas, and in earlier years there was little demand for scientists trained in research. Consequently, most of their efforts were confined to undergraduate teaching and it was difficult for them to retain graduates and build up postgraduate schools. On its establishment, the Council took over the functions of the defunct Research Grant Board as the principal agency for the distribution of funds made available by the Government of South Africa for the promotion of scientific research in the universities, and immediately pressed for a substantial increase in the appropriation for this purpose. Increasing sums are being distributed in the form of bursaries to train postgraduate students in research techniques, to pay for assistants for more senior workers in their researches, for grants towards the running costs of specific programmes, for the purchase of major items of equipment not normally available in university laboratories, and for grants to assist in the publication of completed research.

The allocation is made by a series of selection committees on the basis of individual applications, but the funds are made available in the form of block grants to the universities, which are required to administer them. The Council has up to the present resisted requests from some of the universities for uncommitted lump sum grants rather than individual grants, because it feels that the limited funds available can be expended to the best advantage only on the basis of individual projects considered by a single authority which is in a position to assess the merits of each application in relation to others received from different universities. The universities are, however, strongly represented on all the selection committees.

Medical Research

The Council operates no laboratories of its own for medical research, but, on the advice of its Committee for Research in the Medical Sciences, makes a substantial financial contribution to work in this field.

An annual grant is made to the South African Institute for Medical Research and, in addition, the Council supports some twenty-one small units, groups and major projects in medical schools and hospitals in various parts of the country. The Council's approach in this case has been to single out particular research workers who have already established names for themselves in existing institutions and give them adequate facilities to continue and expand their work. In most cases the scientist continues to hold his appointment in the institution concerned, but the Council supplies additional staff to work under his direction and provides funds for running expenses and any equipment he may need. In this way the Council is assured that any project which it decides to support in the medical field will be led by an experienced and enthusiastic research worker who has already shown himself capable of producing results. On the other hand, should the project later prove to be unprofitable, there is no difficulty in closing it down. At present the Council supports research into the following subjects: amœbiasis, anæsthetic deaths, bilharzia, the biological effects of atomic radiation, the cardio-pulmonary and cardiovascular systems, degenerative diseases and the problems of aging, dental diseases, endocrinology, heart diseases, human biochemistry, nutrition (four separate units each with a different approach), pneumoconiosis, the reactions of the skin to sunlight, tuberculosis and virus diseases (two units).

It is interesting to note that evidence laid before the du Toit Commission, which was appointed by the Government to recommend a future policy for medical research in South Africa, was overwhelmingly in favour of retaining and expanding the present system under the general control of the Council for Scientific and Industrial Research instead of establishing an independent council for medical research. The findings of this Commission await consideration by the Government.

Achievements

It is not easy to assess the value of research, for its results can seldom be expressed in units which can readily be understood. There are, however, a few yardsticks which give at least some idea of what has been achieved.

One of these is publication. Some 800 scientific papers have now been published by staff members in the laboratories of the Council for Scientific and Industrial Research, and 300 have come from medical research units of the Council. To these must be added a further 550 which have flowed from the recipients of bursaries and grants from the Council.

Another yardstick, one which perhaps appeals most to the business man, is finance. We have not attempted to arrive at an exact estimate of the monetary value of the work we have done; this would be impossible, but our rough calculations convince us that actual savings brought about as a result of work done to date in our laboratories have more than covered the total amount spent by the Government on the Council for Scientific and Industrial Research, including the cost of buildings and equipment. As these savings have been brought about for the most part within the past few years as results began to flow from the laboratories, it is obvious that the annual savings will far exceed the annual costs of running the Council. Indeed, we estimate that the measurable savings to South Africa next year will be approximately seven times our parliamentary grant. As a concrete example, we could quote the case of research undertaken by the National Building Research Institute into the design of school buildings on behalf of the Transvaal Provincial Administration. The cost of this investigation was £20,000, and the cost of four of the schools in which the results of the research have been applied within the past two years amounted to £112,000 less than the Education Department would have had to pay had they been built to the old standard pattern with inferior accommodation and facilities. Several other examples, equally impressive, could be quoted.

Discoveries and inventions by the Council's staff are patented only if it is considered that the patent will aid in development of the inventions and thus in application of the results of research. Applications have nevertheless been filed in respect of some thirty-seven inventions. Revenue in the form of licence fees from the few inventions that are now being exploited at present amounts to about £50,000 a year and is increasing rapidly. This is ploughed back into research. Among the more successful of such inventions are the 'tellurometer', which is now being manufactured in South Africa and finding wide application for distance measurement in many parts of the world, and a water desalting process which is being used in the largest plant of its kind in the world on the new Orange Free State goldfields.

These, however, are but the more material results of research due to the Council for Scientific and Industrial Research. Of far greater importance in the long run are the immaterial benefits such as improved health and human comfort, greater productivity in industry and ultimately, we hope, a more contented people. In the universities we now see research being tackled with enthusiasm where practically no research was done before, and in industry we now attempt to solve our own problems where previously we were content to accept without question the dubious applicability under local conditions of technical knowledge imported from overseas. In short, South Africa is becoming conscious of the immense benefits to be derived from the intelligent use of science. This, we claim, is in no small measure due to the activities of the Council for Scientific and Industrial Research.

THE NUCLEAR RESEARCH CENTRE, GRENOBLE

THE Nuclear Research Centre at Grenoble, a further establishment under the control of the French Atomic Energy Commission, was officially opened on January 26.

The creation of this Centre under the French Government's general policy of decentralization is a further step towards increasing the research facilities of the French Atomic Energy Commission.

The Grenoble Centre (C.E.N.G.) will operate in close liaison with the city's University, which possesses laboratories in several branches of science of considerable repute (electrostatics and metal physics, science of low temperatures, fluid mechanics, chemistry, electronics, and so forth) plus excellent engineering faculties, and in particular a special atomic engineering course.

The director of the Centre, Prof. Louis Néel, member of the Paris Academy of Sciences, is also director of the Ecole Nationale Supérieur d'Ingénieurs of Grenoble and the Electrostatics and Metal Physics Laboratory of the Centre National de la Recherche Scientifique.

The first construction programme for the Nuclear Research Centre at Grenoble was completed in two years, on an extensive site close to the city. The programme comprised a number of modern laboratories suitable for a wide variety of research work, two large hangars of industrial type for noisy or bulky experiments, workshops and general services buildings. Facilities comprise the reactor *Mélusine* and a group of five electrostatic accelerators. *Mélusine* owes its name to a water sprite, which according to local tradition haunted the caves of Sassenage, near Grenoble. It is a 20 per cent enriched uranium pool reactor, of 1,200 kW. power, neutron flux 10^{13} neutrons/cm.^{2}/sec. It was built by the French industrial group "Indatom", and the fuel elements are obtained from the United States.

The accelerator building will be equipped in April with one fast neutron generator and four electrostatic accelerators (two ion accelerators, two electron accelerators) with potentials ranging between 600 kV. and 1·4 MV. Their special characteristic is a very high particle current (4 m.amp. with the 1·4 MV. ion accelerator) obtained with a type of electrostatic generator designed in one of the laboratories of the University of Grenoble, and built by the S.A.M.E.S., a company specializing in electrostatic machines.

The research programme of the Grenoble Centre is distributed over a number of 'laboratories'. Research in physics includes the activities of the solid state physics laboratory, where the effects of neutron bombardment on matter are studied, in close conjunction with the low-temperature laboratory, ex-

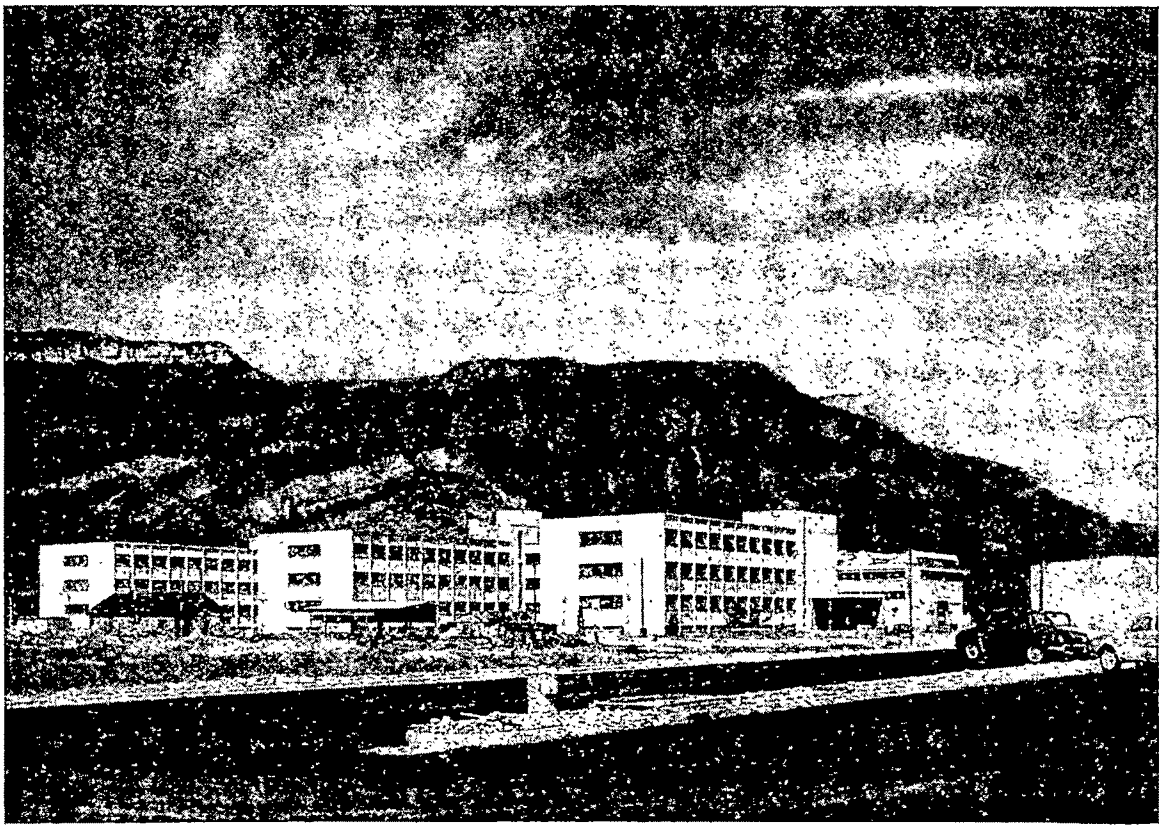

Fig. 1. Laboratory buildings at the Centre d'Etudes Nucléaires de Grenoble

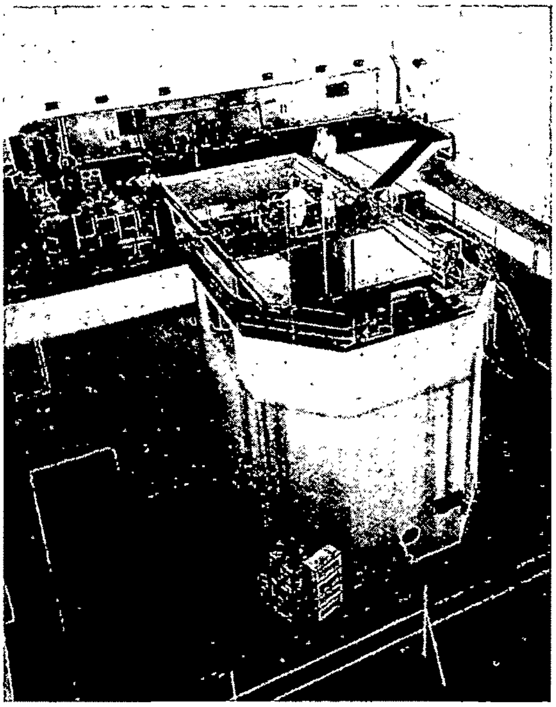

Fig. 2. Swimming pool reactor *Mélusine*

tending this research into the range of 20–900° K., and also the work of the neutron diffraction and magnetic resonance laboratories.

A radiochemistry laboratory has been installed in the Centre by the French Petroleum Institute, while the chemistry of solids laboratory is working on the production of a uranium compound for nuclear fuel elements.

There are, of course, also electronic laboratories, others for the study of applications of radioelements, and biology and nuclear physics laboratories, and also the thermal exchange laboratory, where heat exchanges with liquids in a reactor are studied.

The Centre's research programme is prepared by a scientific committee composed of six representatives from the Atomic Energy Commission and six professors from the University of Grenoble, who are scientific advisers to the Centre. This ensures the essential co-ordination with the programmes of other Atomic Energy Commission research centres.

As from January 1, the research work of the Centre is employing 300 persons. Construction is continuing, and the total staff by the end of 1961 will be 800.

In order to help in obtaining the required number of staff, the Centre collaborates with the organizations entrusted with the training of technicians at all levels. It is also pleasant to note that the Centre is situated in a region that is both industrial and of tourist interest, in the heart of the French Alps, and therefore considered particularly attractive by young technicians.

OBITUARIES

Prof. A. H. Gibson

PROF. ARNOLD HARTLEY GIBSON, emeritus professor of engineering in the University of Manchester, died on February 16 at the age of eighty.

Those who have read Prof. Gibson's monograph on Osborne Reynolds will realize how much 'A. H. G.' admired his own teacher. That he shared some of Reynolds's versatility is clear from the fact that although he will best be remembered for his contributions to hydraulics, he also did significant work in structures (the 'circular-arc bow girder') and in applied thermodynamics (many papers on internal combustion engines and heat transmission). At one period he was simultaneously a member of the Air Ministry Engine Research Committee and of the Severn Barrage Committee.

In hydraulics, his investigations ranged from the behaviour of bodies floating in vortices to river models; from water hammer in pipes to the effect of bridge piers on tides; from centrifugal pumps to the interaction between passing vessels. His famous treatise "Hydraulics and its Applications" was published in 1908; the fifth edition appeared in 1952: he was then seventy-four years old and told me how much he would have liked to rewrite it, but he feared that in that case the price would have been beyond the reach of many for whom the book was intended. The chapter on scale models which he added is probably his last published work.

His writings have an unfailing clarity and directness, virtues which were also very evident in the unaffected elegance of his lectures. He knew just when to stop before confusing the issue.

Gibson's reports on the Severn tidal model (1933) have rightly been described as 'monumental' (an adjective which caused him some amusement). The scope and variety of the experiments—the trials on bed materials, the introduction of silt and the representation of the coagulating effect of the salts of the sea, together with the study of the tides and the bore—remain unsurpassed in this field, even allowing for the later growth in the size of models. His investigations of the Severn and other estuaries revived British interest in the possibilities of scale models as an aid to the design of river and harbour works and led to the creation by the Department of Scientific and Industrial Research of the Hydraulics Research Station at Wallingford.

Generations of students have held him in affection as well as admiration, and one reason for this is to be found in his own interpretation of the duties of a professor. His aim was to inspire and never to 'spoon-feed'. He not only believed that he ought to lecture to each year but also he enjoyed doing so. The course of twenty or twenty-five lectures which he delivered to students in their first term at Manchester, covering a wide field of applied mechanics, brought immediate contact, and this was renewed in the second and third years. At one time or another he lectured on almost every subject in civil and mechanical engineering. Yet in addition he took his full share in the general work of the University in Senate, faculty and committees and maintained his output of important original papers.

The fact that he was able to do so much can be partly explained by his gift for making quick decisions. As Prof. J. A. L. Matheson has written elsewhere, "Gibson was a swift and brilliant intuitive worker. He could recognize a problem, build the apparatus, carry out the experiments and write up the results at a quite astonishing speed . . .". He was equally happy in guiding and encouraging his colleagues and research students. When he saw you baffled, he would blow a ring of tobacco smoke and say, "If I were you, I would try . . .".

Gibson enjoyed good books (which he read with a speed like that of his own writing) and works of art. He detested the pompous and the shallow equally. He sought no honours, but those intimate with him saw that he was made happy and proud by such distinctions as the Ewing Medal of the Institution of Civil Engineers and the honorary degrees of LL.D. conferred upon him by St. Andrews and Manchester. It is probably true, however, that the D.Sc. which he won at Manchester fifty years ago remained his favourite.

Naturally, his name is linked most prominently with the Beyer chair in his Alma Mater (1920–49), but he spoke with great affection of his period in Dundee as professor of engineering in the University of St. Andrews (1909–20, interrupted by service during the First World War in the Army and at Farnborough).

Perhaps no truer or more fitting tribute could be paid to 'A. H. G.' by those of us who had the happy experience of being his students and colleagues than to say that we feel the same veneration for him as he felt for Osborne Reynolds. JACK ALLEN

Prof. G. V. Douglas

GEORGE VIBERT DOUGLAS died suddenly in Toronto, Canada, on October 8, 1958, at the age of sixty-six. From 1932 until his retirement in 1957 he was Carnegie professor of geology at Dalhousie University in Halifax, Nova Scotia.

Prof. Douglas was born in Montreal in 1892. At McGill University he studied under F. D. Adams, but this training was interrupted by the First World War and he went overseas in 1915. He served in France and Flanders with the 17th Battn. Northumberland Fusiliers and, for a short time, with the Royal Engineers. He was awarded the Military Cross and mentioned in dispatches. He returned to Canada in 1919. He graduated from McGill in 1920 and received his M.Sc. degree in 1921.

He spent the next two years in the Antarctic as geologist with Shackleton's last expedition. While working up the results of the expedition, he was able to work in the University of Cambridge. This was followed by further work at Harvard University, where he held a part-time post as instructor under Daly. In 1926, he became chief geologist for the Rio Tinto Company—at first in Spain and later on the Rhodesian Congo Border concession. In 1932 he left the Rio Tinto Company to take up the post at Dalhousie which he held for the remainder of his active life.

Prof. Douglas was a notable factor in the lives of a whole generation of students. Undoubtedly his greatest influence arose from his ability to inspire enthusiasm and to encourage the student to do the best of which he was capable. A secondary influence was his own wide-ranging interest, and one recalls vividly the stimulus of an afternoon at his home, when ideas (some good, many otherwise, no doubt) flew like shuttlecocks as the teacher encouraged his students to exercise their wits. Ideas strongly held often plunged him into controversy but, though many disagreed, there were none who did not admit his courage and integrity.

He is survived by his wife, two daughters and two sons, and by his sister, Dr. A. V. Douglas, of the Department of Astronomy, Queen's University, Kingston, Ontario. G. C. MILLIGAN

NEW FELLOWS OF THE ROYAL SOCIETY

AT a meeting of the Royal Society on March 19, the following were elected to fellowship of the Society:

DR. G. H. BEALE, senior lecturer in genetics in the University of Edinburgh (Institute of Animal Genetics), distinguished for his researches on the genetics of flower pigments and on nucleus–cytoplasm relations in *Paramecium*.

PROF. F. BERGEL, professor of chemistry in the University of London, at the Chester Beatty Research Institute of the Institute of Cancer Research, Royal Cancer Hospital, distinguished for his work in synthetical organic chemistry in the field of vitamins and drugs.

DR. ANN BISHOP, director of the Medical Research Council Group for Research in Chemotherapy, at the Molteno Institute of Biology and Parasitology, Cambridge, distinguished as a protozoologist and especially for her work on the malaria parasite and its resistance to drugs.

PROF. G. E. BLACKMAN, Sibthorpian professor of rural economy in the University of Oxford (Department of Agriculture), distinguished for his research work on the ecology of wild and cultivated plants and on weed-killers.

PROF. H. BONDI, professor of applied mathematics in the University of London (King's College), distinguished for his contributions to cosmology, astrophysics and other branches of theoretical physics.

PROF. J. M. CASSELS, professor of experimental physics in the University of Liverpool, distinguished for his studies of high-energy nuclear physics using particle-accelerating machines.

PROF. A. R. CLAPHAM, professor of botany in the University of Sheffield, distinguished for his research upon many important aspects of ecology and taxonomy, especially those relating to British plants.

DR. F. H. C. CRICK, member of the staff of the Medical Research Council Unit for Research on the Molecular Structure of Biological Systems at the Cavendish Laboratory, Cambridge, distinguished for his contributions to molecular biology.

MR. G. B. R. FEILDEN, director of research, Ruston and Hornsby, Ltd., Lincoln, distinguished for his application of scientific principles to the development and design of industrial gas turbines.

DR. D. W. W. HENDERSON, director of the Ministry of Supply Microbiological Research Establishment, Porton, Wiltshire, distinguished for his work on aerosols and the pathogenesis of air-borne infections.

Dr. R. D. Keynes, lecturer in physiology in the University of Cambridge, distinguished for his work on ionic movements in nerve and muscle and on the origin of the discharge in electric fish.

Prof. R. J. W. Le Fèvre, professor of chemistry, and head of the School of Chemistry, in the University of Sydney, distinguished for his studies of the physical properties of organic compounds.

Dr. B. H. Neumann, reader in mathematics in the University of Manchester, distinguished for his contributions to the theory of groups.

Dr. S. R. Nockolds, reader in geochemistry in the University of Cambridge (Department of Mineralogy and Petrology), distinguished for his researches on the petrology and geochemistry of the igneous rocks.

Prof. W. C. Price, professor of physics in the University of London (King's College), distinguished for his contributions to chemical physics, especially to spectroscopy.

Prof. G. V. Raynor, Feeney professor of physical metallurgy and head of the Department of Physical Metallurgy in the University of Birmingham, distinguished for his research on the structure of metals and alloys.

Prof. O. W. Richards, professor of zoology and applied entomology in the University of London (Imperial College of Science and Technology), distinguished for his researches in entomology.

Dr. R. E. Richards, lecturer in chemistry in the University of Oxford (Physical Chemistry Laboratory), distinguished for his work on nuclear magnetic resonance and its application to chemical problems.

Prof. C. A. Rogers, Astor professor of mathematics in the University of London (University College), distinguished for his contributions to several branches of pure mathematics, particularly the geometry of numbers.

Prof. A. Salam, professor of applied mathematics in the University of London (Imperial College of Science and Technology), distinguished for his contributions to the theory of elementary particles.

Dr. R. Spence, chief chemist and head of the Chemistry Division, Atomic Energy Research Establishment, Harwell, distinguished for his work on the chemistry of radioactive elements, and for his leadership of the Chemistry Division of Harwell.

Dr. J. F. Tait, Worcester Foundation, Shrewsbury, Massachusetts, U.S.A., distinguished for his work on the hormones of the suprarenal cortex.

Mrs. S. A. S. Tait, Worcester Foundation, Shrewsbury, Massachusetts, U.S.A., distinguished for her work on the hormones controlling the distribution of salts in the body.

Dr. M. H. F. Wilkins, deputy director of the Medical Research Council Biophysical Research Unit, at the University of London (King's College), distinguished for his contributions to the development of reflexion and interference microscopy, and for his work on the structure of nucleic acids.

Prof. S. W. Wooldridge, professor of geography in the University of London (King's College), distinguished for his researches on the geomorphology of south-eastern England.

NEWS and VIEWS

The United Kingdom Atomic Energy Authority

The organization of the United Kingdom Atomic Energy Authority is to be changed as from July 1. Hitherto the Authority has been made up of three groups: the Research Group, the Weapons Group and the Industrial Group. The Industrial Group, which has become too large for convenient management, will now be divided into two: the Development and Engineering Group; and the Production Group. At the same time, the full-time technical members of the Authority will again assume executive responsibility for particular Groups, in addition to their functional responsibilities and general duties as members of the Board. Sir William Cook, with the title of Member for Development and Engineering, will be executive head of the Development and Engineering Group and will, in addition, retain corresponding functional responsibilities throughout the Authority. Sir Leonard Owen will have the title of Member for Production (Designate) and will be the executive head of the Production Group. Sir William Penney, whose appointment to succeed Sir John Cockcroft as the Member for Scientific Research has already been announced, will in addition become the executive head of the Research Group, while retaining his functional responsibilities for scientific research throughout the Authority. The appointment of a successor to Sir William Penney as Member for Weapons Research and Development will be announced later.

New Appointments

The following appointments have been made in the Research Group of the United Kingdom Atomic Energy Authority:

Mr. D. W. Fry, deputy director of the Atomic Energy Research Establishment, Harwell, to be director of the Atomic Energy Establishment, Winfrith (*Nature*, 182, 1129; 1958).

Prof. F. A. Vick, professor of physics in the University College of North Staffordshire (*Nature*, 166, 54; 1950), to be deputy director of the Atomic Energy Research Establishment, Harwell. During 1950–54 Prof. Vick was acting-principal of the University College of North Staffordshire. He is a member of the University Grants Committee.

National Research Development Corporation: Appointments

Mr. J. C. Duckworth has been appointed managing director of the National Research Development Corporation as from April 1 in succession to Lord Halsbury, who has been managing director since the formation of the Corporation in 1949 and is now going into industry. Mr. Duckworth, who is forty-two years old, took first-class honours in physics at

Oxford in 1938, and played a leading part in radar research and development during the Second World War. After the War, he was engaged in fundamental nuclear physics research at Chalk River in Canada and at Harwell, and was later in charge at Ferranti, Ltd., of development and design of the guidance and control system of the guided weapon now known as *Bloodhound*. In 1954 he joined the then British Electricity Authority with responsibility for the design, construction and operation of nuclear power stations, and is at present chief research and development officer of the Central Electricity Generating Board.

Mr. Dennis Hennessey has been appointed by the Corporation to a new post of deputy managing director. Mr. Hennessey, who was a former principal patents officer at the Ministry of Supply, joined the staff of the Corporation in 1950 at the age of thirty-eight and was made an executive member of the Corporation in 1956.

Government Research on Food Preservation

THREE research stations of the Department of Scientific and Industrial Research, all concerned with the preservation, storage, handling or protection of foodstuffs, will be transferred to the Agricultural Research Council on July 1. They are the Ditton Laboratory at Larkfield, Kent, the Low Temperature Research Station at Cambridge, and the Pest Infestation Laboratory at Slough. The agreement between the Council for Scientific and Industrial Research and the Agricultural Research Council—announced in the House of Lords by the Lord President of the Council, Lord Hailsham, on March 4—was made because the two Councils consider that Government research on food other than fish would be more effectively pursued under one authority. The staff in the three laboratories, numbering about 200, will be invited to transfer to the service of the Agricultural Research Council.

Agriculture at Aberdeen : Prof. J. R. Raeburn

DR. J. R. RAEBURN, recently nominated to the Strathcona–Fordyce Chair of Agriculture at Aberdeen, in succession to Prof. A. B. Stewart, who has been appointed director of the Macaulay Institute for Soil Research (see *Nature*, 181, 1105 ; 1958), was educated at Manchester Grammar School, at the University of Edinburgh and at Cornell University. His career has been one of widely varied experience in research, teaching and administration. He did practical farm work in Scotland during 1928–29, and was engaged in research at the Edinburgh Animal Breeding Research Institute during 1932–33, before proceeding to his doctorate at Cornell. During 1936–37 he had the unusual experience of serving at the University of Nanking under Prof. Buck, whose collection of information on the subsistence agriculture of Chinese peasants is unsurpassed in any other such country. The agriculture of African and Asian peasants has been one of Dr. Raeburn's principal fields of research and teaching during his tenure of the readership in agricultural economics in the University of London since 1949. He has travelled extensively and has been much consulted by the Colonial Office on the development of its agricultural policy. During the Second World War he served in the Ministry of Food as secretary of the Home Agricultural Supplies Committee, the duty of which was to plan the development of home supplies in such a way as to give the maximum release of shipping space. During 1938–39 and 1946–49 he was a research officer at the Oxford Agricultural Economics Research Institute. At an early age Dr. Raeburn was recognized as an outstanding figure in his own fields of research. His work combines extensive knowledge and experience with subtle and sympathetic understanding of the difficult problems of decision which every farmer has to face, and strong criticism of some unreliable methods of sampling used in obtaining agricultural economic information.

The Jodrell Bank Radio Telescope

IN replying on an adjournment debate in the House of Commons on March 4, in which Mr. R. E. Winterbottom and Lt.-Col. W. H. Bromley-Davenport had, while supporting the Committee of Public Accounts, pleaded for a more generous attitude from the Government in meeting the outstanding £140,000 on the Jodrell Bank Radio telescope, Mr. H. Nicholls defended the Government's attitude and, outlining the financial history in some detail, claimed that the Government from the first had given all the help it possibly could, within the limits of sound financial control, to this great project. Out of eight recent major university schemes costing more than £100,000 each which are being supported by the Department of Scientific and Industrial Research, three, including the Jodrell Bank project, had come under the ægis of the University of Manchester, and Mr. Nicholls did not think that the University had been treated ungenerously. The Government did not want to discourage the universities and scientists from embarking on similar projects which would place Britain in the lead in the future, but it must know on what the money was being spent before it was granted. It must also respect a second principle, that if the cost of any project is liable to be greatly increased, the Government department concerned must be kept clearly informed from start to finish and should agree to the extra expenditure before being held liable for it. Mr. Nicholls promised to report to the Lord President what was said in the House.

Transient Reactor Test Facility achieves Criticality

THE Transient Reactor Test Facility (*Treat*), a reactor designed to investigate the effect of extreme nuclear heat upon fast reactor fuel elements, achieved criticality at 23.30 E.D.T. on February 23 at the U.S. Atomic Energy Commission's National Reactor Testing Station, Idaho Falls, Idaho. The reactor, designed by the Argonne National Laboratory, can deliver a high-intensity, short-duration surge of nuclear energy without damage to the facility itself. The surge will result when a large number of atoms undergo fission in a short time and will cause intense heat to be generated in the sample being tested. The surge will be useful in simulating abnormal reactor operating conditions and will permit reactor designers to observe on a small scale the effect of such conditions on prototype fuel elements planned for fast reactors. The facility, which resembles a research reactor, is fuelled with uranium oxide uniformly dispersed in graphite. The graphite lsows down the neutrons produced by the fission of uranium atoms, enabling the neutrons to collide with other uranium atoms to continue the chain reaction. During the surge, the abnormal amount of heat generated in the fuel due to fission is transferred instantaneously to the graphite, which absorbs the released energy. As the graphite becomes heated, its efficiency in slowing down the neutrons decreases. Consequently fewer neutrons capable of producing fission are available, permitting the surge to be held to a safe level. For this reason, the reactor is said to have self-limiting operating characteristics.

Research in Tropical Medicine

The U.S. National Academy of Sciences–National Research Council is to organize a major survey of needs in the field of tropical medicine, under the direction of Dr. W. H. Wright, who recently retired as chief of the Laboratory of Tropical Diseases, National Institutes of Health. The survey will embrace the fields of infectious and parasitic diseases, veterinary medicine, and environmental hygiene. It will include surveys of disease problems in tropical and sub-tropical areas of significant importance to public health and to agricultural and industrial development; of funds expended for medical care and disease control; of financial support for research in medical and hygienic problems of the tropics; of fellowships, teaching programmes, and training facilities; of careers and incentives; of the impact of travel and migrations on tropical disease problems; of the importance of tropical medicine to the economy and man-power situation in the United States. On the basis of these findings it should be possible to assess the need for domestic, foreign and international measures to deal with the problems defined in the survey.

Scientific Linguists in the United States

An inquiry by the National Science Foundation into the knowledge of foreign languages possessed by American scientists indicates that 97,000 of the 127,000 on the National Register of Scientific and Technical Personnel during 1954–55 (probably more than half of all American scientists) possessed a knowledge of at least one foreign language, German being the commonest, and French coming next. In psychology and the earth sciences, proportionately greater numbers reported knowledge of French, Spanish and other Romance languages, but only about 1 in 50 reported a knowledge of Russian and fewer than 1 in 100 of Chinese.

Science Laboratory Technicians

The City and Guilds of London Institute and the Institute of Science Technology announce that they have taken important steps to rationalize their examinations and qualifications for science laboratory technicians. Hitherto, both Institutes have held such examinations, but in future there will be only one series, held by the City and Guilds of London Institute on behalf of both Institutes. The conduct of the examinations and their further evolution will be under the guidance of a joint advisory committee of both Institutes and the certificates awarded to successful candidates will bear the heading: "The City and Guilds of London Institute in conjunction with the Institute of Science Technology". Transitional regulations have been agreed to ensure that no student at present preparing for the examinations of the Institute of Science Technology suffers because of the new arrangements. The arrangements for the award of the Fellowship of the Institute of Science Technology remain unchanged.

Soddy's Cubic Equation Machine

Frederick Soddy was always looking beyond the borders of his main field of activity, and on several occasions he invaded mathematics. He took a great interest in locating circles within circles, and in calculating the radius of an inside circle he derived a cubic equation, which suggested the possibility of using a geometrical construction for solving the associated cubic equation. He thereupon made a machine with strings and pulleys which, when set with magnitudes derived from a cubic with numerical coefficients, would indicate the corresponding roots if they were all real. After the Second World War he made a machine with pivoted levers and scales which did the same operation without employing strings. In his will he provided for the exploitation of this machine, but this proved impracticable, largely because of the speed with which actual cubic equations can be solved with electronic computers, and his device required some calculations before it could be properly set. His attempt is, however, of some historical interest, and the model has been handed over to the Science Museum.

Applied Mathematics in the Soviet Union

Appreciation in the West of the substantial contributions made by Soviet scientists to the study of topics in applied mathematics, such as, for example, the mathematical theory of elasticity, has sometimes been delayed by linguistic difficulties; the summaries available give valuable indications of content, but not always of method. The American Society of Mechanical Engineers has secured a grant from the National Science Foundation which will enable the Pergamon Institute to translate the important periodical, *Prikladnaia Matematika i Mekhanika* (Applied Mathematics and Mechanics), and to publish it as a bi-monthly journal. The aim is to give an exact translation of the original papers, with editorial glosses or comment kept to a minimum. The present series begins with Vol. 22 (No. 1; 1958) of the original, which contains papers accepted during 1956 and 1957, so that translation and re-publication do not seem to have added substantially to the normal time-lag between acceptance and publication. The enterprise should prove of great value to mathematicians in Great Britain and the United States. The annual subscription is 35 dollars or £12 10*s*., and orders can be placed with the Pergamon Press in London or New York.

Educational Research

First launched some three months ago, this new journal contains information about educational research which should be of interest to practising teachers, local authorities, administrators and other educationists. The articles are particularly valuable because they indicate what may be accepted as established fact, what may reasonably be inferred, and the bearing of the topics referred to upon the day-to-day life of the school and the thought and practice of the teacher. The February issue of the journal (1, No. 2) describes the effects of size of class on teaching, differences between education in town and country, how children understand numbers, and compares the methods of teaching reading. The contributors include well-known educationists, including Sir Cyril Burt and Dr. C. M. Fleming. Future issues are to include articles on the teaching of modern languages; research in technical education; the gifted child; bilingualism; testing attainment; and children's vocabulary. The new journal is issued three times a year in step with school and college terms. It can be obtained from the publishers, Newnes Educational Publishing Co., Tower House, Southampton Street, Strand, London, W.C.2.

Grants to Students in Britain

A MEMORANDUM submitted by the National Union of Students to the Committee on Grants to Students set up by the Minister of Education and Secretary of State for Scotland under Sir Colin Anderson as chairman has now been published (pp. 28. London: National Union of Students, 1959). Its seventeen recommendations include the financing of awards entirely by the Government and administration by a central grant-awarding authority, or alternatively and as an interim measure, that the awards should be financed mainly by the Ministry of Education, with a proportion to be met from a pool to which all local education authorities should contribute. Awards should be given to those selected by universities for first-degree courses and for comparable courses in other institutions of higher education and the relevant authorities should be invited to review the standard set in 'closed' scholarship examinations. University authorities are urged to consider the practicability of establishing a clearing house system for dealing with university applications, and a review of the values of university scholarships and removal of their maintenance factor are also recommended. In the light of the university review an honorarium for State scholars should be agreed, while the system of supplementation by the Ministry should be ended and the numbers of State scholarships offered should be reviewed each year. Non-recurrent prizes gained in open competition during the course should be tenable without reduction of grant, and awards should also be granted on acceptance to students taking full-time or sandwich courses of degree study at technical colleges or courses recognized by the Ministry of Education as being of comparable status, and these awards should be assessed on the State scale for major awards. It is also recommended that awards should be made without reference to the parental income and that the values of awards should be reviewed every two years instead of every three years.

Graduates in British Industry

THE Information Division of the Department of Scientific and Industrial Research has issued under the title "Graduates in British Industry" (pp. iv+28. London, 1958) a short record of the main findings and applications likely to be of value to firms recruiting graduates, and also to graduates newly appointed to jobs in industry, of the two reports "Graduate Employment—a Sample Survey" and "Graduates in Industry" published by Political and Economic Planning. The record is illustrated with diagrams and the main pointers for management are summarized in the final section. The conclusions from the inquiry are also given concisely following eight short sections dealing with various aspects of the subject.

Atmospheric Temperatures

METEOROLOGISTS, aviators, and those concerned with the planning of air routes, often require information about the winds and temperatures which may be expected in different parts of the globe at various levels. Winds are usually more important, and the Meteorological Office published its Geophysical Memoir No. 85 some time ago to meet this urgent need. Now a companion Memoir, No. 101, has been published, giving temperature information for all parts of the Earth except those regions south of latitude 60° S., mainly at the standard pressure-levels 700, 500, 300, 200, 150 and 100 mb., which range from 10,000 ft. to 56,000 ft. approximately. The presentation involves variation with place, height and time, and is necessarily done graphically, but the nature of the variations is complicated by the variations in the tropopause-level. When any point is sometimes in the troposphere and sometimes in the stratosphere, the temperature variations are normally bimodal, that is to say, the distribution curve shows two peaks, one corresponding to tropospheric and the other to stratospheric events. In this case, special care must be taken in interpreting the data, and it is inevitable that the Memoir contains a great deal of information about the tropopause and its average movements. This, particularly, will interest the meteorologist. The sources of the data have been carefully listed; but a map showing the distribution of the observing points might have been a valuable guide to the extent to which it has been necessary to interpolate over various areas. For example, it has not been possible to include any data since 1952, and sometimes data from adjacent areas are taken for different years. This must sometimes cause apparent changes from place to place due to the different regimes which occur in different years, and there must be very few results from areas between 35° S. and 60° S. The present Memoir is welcome, but even though it has just appeared we shall look forward to a new edition, revised in the light of the very much greater volume of information obtained during the International Geophysical Year.

Assistance from the International Atomic Energy Agency

A PAMPHLET, "Technical Assistance" (pp. 16. Vienna: International Atomic Energy Agency, 1958), outlines the services available from the International Atomic Energy Agency, describing first the kinds of assistance, including fellowships and exchange visits, the provision of advice and information on nuclear energy problems and equipment, and secondly the fields in which member States can request assistance from the Agency. Those listed include library and documentation services; ore prospecting, mining and processing; the design, construction and management of nuclear research laboratories and centres; nuclear research; nuclear reactors; the use of radioisotopes; safeguards; and problems of health, safety and disposal of waste. Thirdly, rules and practices governing assistance are detailed.

Craters on the Moon

RECENT reports of a volcanic eruption near the lunar crater Alphonsus have apparently stimulated fresh experiments and speculation on the origin of these craters. Apart from the well-known meteoritic and volcanic theories, F. Benario suggested some years ago (*The Strolling Astronomer*, 7, 19; 1953) that a bursting bubble of gas could produce a crater of similar form. In a recent letter, Dr. A. G. Gaydon and R. C. M. Learner (*Nature*, 183, 37; 1959) showed photographs of crater-like formations produced by gas effusing through a light dry powder under vacuum. There appears to be some confusion between the two latter experiments, which are in reality quite different. In Benario's work, the sudden bursting of a gas bubble (in a slurry of plaster of paris, water, and 'Alka-Seltzer') was observed. In Gaydon and Learner's experiments, the crater wall was built up quite slowly by a continuous fountain of falling dust. The latter experiment is more related to volcanic action, but assumes a fall of dust or ash, as at Pompeii, rather than a flow of molten lava. A flow of lava would be expected to build a high mountain, whereas the fall of dust could form a shallow crater of large diameter.

Supplies of Follicle-stimulating Hormone

THE Endocrinology Study Section, U.S. National Institutes of Health, announces that it is prepared to distribute, free of charge to qualified investigators, limited amounts of purified sheep pituitary follicle-stimulating hormone. The preparation has been packaged in two forms: (1) vials containing 5 mgm. for use only as a standard in assay procedures; (2) vials containing 25 mgm., for experimental use. The preparation is a sterile, lyophilized powder, free or nearly free of other hormonal activities. Detailed specifications will be distributed with each sample. Application for supplies should be made to the executive secretary, Dr. R. T. Hill, Endocrinology Study Section, National Institutes of Health, Bethesda 14, Maryland, with a brief outline of the intended work and an estimate of the amount needed. Allocations will be made after consideration of the merits of the intended work.

The Night Sky in April

NEW moon occurs on April 8d. 03h. 29m. U.T. and full moon on April 23d. 05h. 13m. The following conjunctions with the Moon take place: April 11d. 06h., Venus 5° N.; April 14d. 11h., Mars 7° N.; April 25d. 00h., Jupiter 3° S.; April 27d. 14h., Saturn 4° S. In addition to these conjunctions with the Moon, Venus is in conjunction with Aldebaran on April 23d. 14h., Venus being 7·2° N. There will be an annular eclipse of the Sun on April 8, invisible at Greenwich. The path of annularity crosses Australia. Mercury is unfavourably placed for observation. Venus is an evening star, visible in the south-west after sunset. Conditions are very favourable for observation. Venus sets at 21h. 35m., 22h. 20m. and 23h. 00m. on April 1, 15 and 30, respectively; its stellar magnitude is − 3·5. Its distance decreases during the month from 122 to 104 million miles and the visible portion of the visible disk decreases from 0·828 to 0·734. Mars is moving eastwards among the stars and passes from Taurus into Gemini during April. It sets at 1h 25m., 1h. 05m. and 0h. 40m. at the beginning, middle and end of the month, respectively. Its stellar magnitude decreases from + 1·3 to + 1·6, its distance from the Earth increasing from 148 to 173 million miles. Jupiter rises at 23h. 10m., 22h. 10m. and 21h. 00m. on April 1, 15 and 30, respectively; it is near β Scorpii. The stellar magnitude of Jupiter is − 2·0; its distance on April 15 is approximately 420 million miles. Saturn is a morning star in Sagittarius, rising at 2h. 00m., 1h. 05m. and 0h. 00m. at the beginning, middle and end of the month, respectively. Its stellar magnitude is + 0·7; its distance from the Earth on April 15 is approximately 910 million miles. There are no occultations of stars brighter than magnitude 6 observable from Greenwich. The Lyrid meteors are active during April 20–22, but conditions are unfavourable.

Announcements

THE 1958 James Clayton Prize of the Institution of Mechanical Engineers has been awarded jointly to William Munger Heynes (director and chief engineer, Jaguar Cars, Ltd., Coventry) for his outstanding contribution to the design and development of the modern automobile, and to Sir F. Ewart Smith (deputy chairman, Imperial Chemical Industries, Ltd.) for his personal contribution to the advancement of mechanical engineering, particularly in the chemical industry, and to the training of engineers. This prize is awarded annually to a member or members of the Institution who, in the opinion of the Council, contribute most in the year to modern engineering science by research, invention, experimental work or a treatise or paper on a modern engineering subject, or originality in engineering design or by service to engineering.

HARRY POLACHEK, technical director of the Applied Mathematics Laboratory of the David Taylor Model Basin, has recently been appointed chairman of the editorial committee for the quarterly journal *Mathematical Tables and Other Aids to Computation*, published by the Division of Mathematics of the U.S. National Academy of Sciences—National Research Council. He succeeds C. B. Tompkins of the University of California at Los Angeles, who has held the post since November 1954. Articles for publication in the journal should in future be addressed to Harry Polachek, editor, *Mathematical Tables and Other Aids to Computation*, David Taylor Model Basin, Washington 7, D.C.

A SYMPOSIUM on "Oxidation" is to be held in Queen Mary College, London, on April 13 and 14. It is intended to provide an opportunity for discussing the present state of knowledge of the oxidation of organic compounds in the liquid phase and in particular by chromic acid and permanganate. Inquiries can be addressed to Dr. W. J. Hickinbottom, Department of Chemistry, Queen Mary College, London, E.1.

THE tenth Conference of the British Occupational Hygiene Society will be held in Stephenson Hall, University of Sheffield, Oakholme Road, Sheffield, 10, during April 14–15. The Conference, which will be devoted to a discussion of the control of dust and fumes in industry, is to be opened by H.M. Chief Inspector of Factories. Papers will be presented by speakers with experience of the subject in the cotton and asbestos industries, in iron foundries, in welding and electro-plating. Non-members are eligible to attend this conference on payment of a registration fee. Further details can be obtained from the honorary scientific secretary, Dr. D. Turner, The Associated Ethyl Company, Ltd., Ellesmere Port, Cheshire.

THE third meeting of the Welsh Soils Discussion Group will be held on April 19 at the National Agricultural Advisory Service Centre at Trawscoed, near Aberystwyth, when Dr. Rice Williams will open a discussion on "The Soils of the Aberystwyth Area" and arrange for local field inspection of selected soil series. This meeting will occupy most of the day, and arrangements will be made for lunch at Trawscoed. Members of the Group, and others interested, can obtain further information from the secretary of the Group, Mr. J. A. Taylor, Department of Geography, University College of Wales, Aberystwyth.

PROBLEMS OF COLLECTIVE MOTION IN PHYSICS

A CONFERENCE on various aspects of collective behaviour in physics, sponsored by the Physical Society, was held in the Department of Physics in the University of Birmingham during January 2–3; the visitors were received by the vice-chancellor, Dr. R. S. Aitken. It was hoped that the main talks would be suitable as an introduction to the subject for theoretical physicists not familiar with the theory of collective motion and also for experimental physicists. It must be said, however, that apart from the talks on the electron theory of metals and on liquid helium, the talks were clearly addressed to physicists actively working on the subject under discussion: this was even more the case with the discussions.

The first session was devoted to gaseous plasmas. W. B. Thompson (Atomic Energy Research Establishment, Harwell) described a method for deriving the hydromagnetic equations by taking suitably chosen moments of the Boltzmann equation in cases in which collisions may be neglected. This procedure is the counterpart to the Hilbert–Chapman–Enskog method of deriving the equations of ordinary hydrodynamics. S. F. Edwards (Manchester) discussed methods of describing the dynamics of a plasma in thermal equilibrium, including a derivation of the Debye–Hückel screened potential, of the equation of state, and of the plasma oscillation frequency. He also discussed briefly a variational method for deriving the electrical conductivity of a plasma. In the discussion following these two papers it was pointed out that although the equations used by Thompson will break down, thus indicating the possible occurrence of shock-waves, they cannot be used to describe such shock waves as they are essentially an adiabatic approximation. R. Balescu (Brussels) reported briefly on work in Prigogine's group on obtaining by iteration methods asymptotic solutions of the Liouville equation valid for long times and large distances.

The second session dealt with plasma problems in the electron theory of metals. S. Raimes (Imperial College of Science and Technology, London) gave a lucid account of the Bohm–Pines theory of plasma oscillations in metals and of their introduction of a cut-off wave-number k_c above which no collective degrees of freedom will occur. He discussed the shortcomings of Pines's original variational method for determining k_c. Dr. Raimes then showed how this theory can account for the observed density of states curve for such metals as sodium, pointing out the importance, shown by Fletcher and Larson, of second-order effects. In the discussion, Prof. H. Fröhlich (Liverpool) pointed out that k_c should be determined by using a trial wave function in conjunction with the correct Hamiltonian, and not with an approximate Hamiltonian as was done by Pines. S. F. Edwards (Manchester) and R. Leigh (Atomic Energy Research Establishment, Harwell) reported on work in progress along those lines. Edwards is using wave-functions including two-body correlations, whereas Leigh uses wave-functions of the de Shalit–Weisskopf type. In this connexion Fröhlich suggested the consideration of a one-dimensional plasma for investigating the accuracy of the results obtained. D. Bohm (Bristol) discussed the difficulties connected with degrees of freedom with wave-numbers of the order of magnitude of the Debye wave-number. In that connexion, C. G. Kuper (St. Andrews) reported work on a charged boson gas, where a Bogoliubov-type transformation can be used leading to a smooth transition from particle to collective degrees of freedom.

The third session covered liquid helium and superconductivity. The talk by G. V. Chester (Birmingham) was probably for most people one of the most interesting aspects of the conference. In it he discussed the four main kinds of collective motion which occur in liquid helium below 1·6° K. These are the superfluid hydrodynamic potential flow, phonons, rotons and the Onsager–Feynman vortices. Feynman and Cohen's determination of the excitation spectrum was dealt with, and also the experimental work of Hall and Vinen which shows the existence of vortex lines and probably their quantization. In the discussion following this paper, Prof. H. Fröhlich (Liverpool) and Prof. R. E. Peierls (Birmingham) voiced objections to the Feynman–Cohen calculations, while Kuper directed attention to the influence of self-energy corrections. Both O. Penrose (Imperial College of Science and Technology, London) and Kuper asked how far the concept of independent collective excitations was valid. In reply, Chester said that the inelastic neutron scattering data, on helium II, strongly suggest that the concept is valid up to about 1·7° K.

J. G. Valatin (Birmingham) gave an account of the Bardeen–Cooper–Schrieffer theory of superconductivity, mentioning in passing the work of Martin and Schwinger, Gorkov and Galitskii, who are using a Green function approach. He also briefly discussed how the recent theories can account for the electromagnetic properties of superconductors. A lively discussion followed in which Prof. Fröhlich warned against non-gauge invariant theories, because spurious Meissner effects are only too easily obtained. He also pointed out that in the present form of the theory the total momentum fluctuates in the superflow. These fluctuations and those in the number of quasi-particles make it difficult to prove that a superconductor in the present theory has, indeed, zero resistance, as was pointed out by Kuper, who also asked when an energy-gap leads to a superconductor and when to an insulator. Prof. Peierls defined a superconductor as a substance in which a current-carrying state with an energy close to the ground-state level is possible, and in which no transitions are possible from such a state to states with lower current densities, not even through intermediate states, as happens in normal metals. Prof. Peierls also pointed out the difficulty of estimating the errors involved in the present theory and suggested an approach similar to Feynman's approach to liquid helium, since in that case a variational method could be used to estimate the energy gap.

B. Bayman (Copenhagen) discussed the Bohr–Mottelson explanation of the 'energy-gaps' found in nuclei. Empirically, it is found that the first excitations of a single-particle nature—as distinct from a collective one—in the region of large deformation are much higher in energy than one would predict from the Nilsson model, in which the particles are assumed to move independently in a distorted well. This can be explained by a correlation between pairs of particles of opposite magnetic quantum number, in an unfilled shell. This pairing in angular momentum is similar to the pairing in linear momentum in the Bardeen, Cooper and Schrieffer model. Bayman discussed calculations of Beliaev, who incorporated the pairing simply by making a transformation to a quasi-particle representation. In the region near closed shells, the pairing correlation leads to so-called vibrational states. Their energy spectrum is essentially that produced by Racah's pairing force, so that many of the results of the seniority scheme can be used. In the discussion J. P. Elliott (Southampton) reported on the status of his generalized shell-model approach, and Prof. Peierls discussed briefly the variational scheme for obtaining rotational levels.

The conference was considered by all present to have been a great success, and I for one hope that another conference on the same subject can be arranged in a few years time to review the progress made in the intervening period. D. ter Haar

INDUSTRIAL HEALTH IN BRITAIN

THE annual report of the Chief Inspector of Factories on Industrial Health for the year 1957* is the first report on industrial health to be published separately and is, to some extent, experimental. Its first chapter, reviewing the year, deals with general questions, including references to new and developing problems and to progress made in solving old problems. The second chapter deals with cases of industrial disease, poisoning and gassing which occurred during the year, and the third chapter deals more extensively with industrial dermatitis. Points which were raised on the statutory draft Compressed Air Special Regulations were all resolved by the end of the year, and the Regulations came into operation on April 21, 1958. The report of the pilot industrial health survey of Halifax was studied in detail by a sub-committee of the Industrial Health Advisory Committee, and afterwards an abridged version of the report was published and arrangements were made for the survey team to approach occupiers of factories in Halifax employing more than 250 workers with the view of interesting them in the advantages of the provision or extension of medical and nursing services.

A committee of inquiry into precautions against anthrax was set up in February 1957, and there was evidence during the year that factory occupiers pay insufficient attention to making adequate provision for first-aid treatment, as required under the Factories Act. In the light of discussions between representatives of Government departments which have responsibilities for first aid, including representatives of the Medical Research Council, the contents of first-aid boxes in factories, as prescribed by the First Aid in Factories Order, 1938, and the leaflet giving advice on first aid treatment have been reviewed, while measures to stimulate recruitment and training of first-aid personnel were also discussed. The third interim report of the Joint Advisory Committee of the Cotton Industry on "Dust in Card Rooms" has been brought to the notice of all firms concerned, and it has been made clear to occupiers that, since a satisfactory system of removing dust in card rooms is now available, it is expected that early action will be taken. Plans were made for extending the Inspectorate's facilities for collecting and analysing dust by formation of a second dust-counting team.

The chapter on industrial dermatitis summarizes known facts on the cause and particularly the prevention of this disease which have already been made known in departmental and other publications. Predisposing factors are also indicated, and stress is laid on the importance of taking appropriate measures before and not after trouble has occurred. These include replacement of the harmful agent by one that is non-irritant or less harmful ; selection of personnel ; reduction of contact to a minimum, or complete elimination of contact ; regular and frequent inspection by trained observers ; and cleansing of the skin.

INTERNATIONAL STANDARDS FOR DRINKING-WATER

THERE is at present a wide diversity in water treatment and quality in different countries, and the need for some sort of international agreement on what constitutes a safe supply of drinking-water has long been apparent. The question was raised at the Congress of the International Water Supply Association in Amsterdam in 1949 and again in Paris in 1952, but the prospect of accord in the near future seemed remote. In 1953 the matter was taken up by the World Health Organization, and a questionnaire was circulated to member States. The replies served to reiterate the differences in attitude, and in view of the increase in international travel, particularly by air, to emphasize the desirability of agreed standards.

Regional study groups of experts were convened to study the problem in the European, Eastern Mediterranean, and South-east Asia and Western Pacific regions. The reports of these various groups were used as a basis for discussion by a further group meeting in Geneva in 1956 and the standards now proposed were put forward by this body. It is not suggested that these standards represent perfection ; on the contrary, as the preface specifically points out, they are tentative and subject to modification after experience of their application. In some cases the standard proposed is not as high as that habitually achieved by some undertakings, but the sources of water supply used for public consumption are so different in their chemical and bacteriological content and treatment methods so limited by technical and financial resources that it is not to be expected that the high standard reached in certain localities will immediately become universally applicable. The standards suggested represent rather the minimum requirements to which a public water supply should conform and in the absence of which it cannot be considered entirely free from risk. This is in itself a great advance and will be of inestimable value to health and water authorities in those parts of the world where at present water supplies do not attain the desired criteria.

In the International Standards for Drinking Water*, recently published by the World Health Organization, a chapter is devoted to each of the subjects of bacteriological, chemical and physical, biological and radiological requirements. This is followed by a section in which are indicated matters requiring further research in each of these fields. In some cases it might appear that the subject suggested for study has already been adequately investigated, but it can do no harm for some old ground to be re-covered if the results are made more widely known and a re-assessment of some cherished beliefs may prove salutary.

In a rapidly expanding subject it is inevitable that a publication of this kind should be somewhat behind the latest information. This applies particularly to the chapter on radiological requirements, which seems unduly brief. There is no mention of the part played by the naturally occurring isotope, potassium-40, in contributing towards the total radioactivity in water, although it is only fair to say that for further information the reader is referred to the recommendations of the International Commission on Radiological Protection.

Any consideration of standards, particularly in the bacteriological or chemical spheres, must take some account of the methods whereby these are measured, and the second, and larger, portion of the book is devoted to a series of approved methods for bacteriological, chemical and biological examination of water. Starting with a list of required materials, each procedure is explained step by step in simple language which is a model of clarity. Not the least important sections are those detailing the particulars to be supplied with samples and the recommendations on the frequency of sampling. Tables are given for the computation of the most probable number index with upper and lower confidence levels. In the chemical section, lists with permissible levels are provided not only of those naturally occurring substances which may affect potability but also of toxic materials such as lead, arsenic, selenium, chromium and cyanide, with details of methods for their estimation.

If one may venture a further minor criticism of so valuable a work, it is that a comprehensive index might have increased its usefulness. As it is, the volume is an excellent example of what can be achieved by international co-operation and a milestone on the way to safe water supplies throughout the world.

THE WEIZMANN INSTITUTE OF SCIENCE

THE report for 1956–57 of the Weizmann Institute of Science*, besides summarizing the scientific activities of the several departments and sections, includes a list of publications during the period and details of the scientific staff, as well as of the administrative and technical staff and supporting committees. It is introduced by a statement of policy for the future of the Institute by Mr. M. W. Weisgal, chairman of the Executive Council, which expresses grave concern regarding the financial position of the Institute. Anticipated income for the four years April 1956–March 1960 fell short of estimated requirements by about 6 million dollars, and the measures proposed by Mr. Weisgal include launching a campaign for an Endowment Fund of 25 million dollars.

Fundamental research in the Department of Applied Mathematics was directed mainly to the solution of mathematical problems in statistical mechanics, wave propagation, geophysics, hydrodynamics and X-ray crystallography. In nuclear physics, besides investigation on nuclear models, some work on reactor physics was undertaken for the Israel Atomic Energy Commission. The Department of Isotope Research records progress in the production of stable isotopes, the use of stable and radioactive isotopes in studying the mechanism of inorganic and organic reactions and in various applications of natural and artificial radioactivity. Investigations by the Department of Organic Chemistry embraced the structure of natural compounds, the chemistry of the sphingolipids, steroid and acetylene chemistry, syntheses in the terpene series, petroleum chemistry and applied spectroscopy.

Besides studies of polyelectrolytes, including their biological aspects, in the Department of Polymer Research, gels, membranes and mechano-chemistry received attention, as well as polynitroethylene, polyvinyl bromide and polyvinylanthracene. The Department of X-ray Crystallography continued to investigate intra- and inter-molecular compression forces on molecular structure and to study the mechanism of solid-state reactions by combined X-ray crystallographic and physico-chemical methods, while work in the Department of Experimental Biology included such diverse fields as the biological mechanism of the induction of tumours, the metabolism of urethane in relation to its tumour-inducing activity, the mechanism of deciduoma formation and its relation to placental implantation of the ovum, immuno-genetics of tumour implantation, radiobiological aspects of tumour immunity, biochemical and endocrinological aspects of sugar metabolism and problems in human genetics and neuropharmacology. The Department of Biophysics continued to be concerned mainly with work on synthetic poly-α-amino-acids and their use in elucidating chemical and physical properties of proteins and natural polypeptides. In the Department of Electronics a more generalized theory of rotational magnetic processes was formulated and several magnetic measuring devices were built. The main effort of the Infra-red Section was on the construction of a large vacuum spectrometer-refractometer for use in the near infrared region; the Section of Photochemistry and Spectroscopy investigated chemical processes involved in photochromic phenomena and the influence of ionizing radiation and high-energy particles on phototropic and photochromic compounds; and the Section of Plant Genetics was concerned with the mechanism of the development of sex in plants.

THE BRITISH FLORA DURING 1958

THE publication during 1958 of a new and authoritative list of vascular plants accepted as established members of the British flora[1], and including some 2,895 species and 538 hybrids, is a timely reminder of the relative thoroughness with which the flora has been investigated. The additions which continue to be made annually are evidence that native plants can be long overlooked even on the best-worked ground, and that new aliens continue to find ecological niches where they can establish themselves in competition with species already present. Comparison of the new list with the last full-scale list of the British flora issued in 1928 shows that since then there has been a net addition of some 370 established species. That botanists can add an average of 12 such species annually (and this takes no account of casuals) shows how rapidly the known British flora is changing.

At the annual exhibition meeting of the Botanical Society of the British Isles, held in the lecture hall of the Royal Horticultural Society on November 29, the exhibits included several interesting additions to the British list. One of these was *Juncus subulatus* from the salt-marsh at Berrow, Somerset, which was shown by E. W. Davies and J. Willis (Bristol). This salt-marsh was formed about 1910, and its development has been under observation since 1921 and has been the subject of several ecological studies[2–5]. Two large and flourishing colonies of the rush are spreading vegetatively by vigorous growth of the rhizomes in the zone of *Scirpus maritimus*—the latter appeared about 1926 and increased extremely rapidly during the next two years[3]. *Juncus subulatus* is widespread in the salt-marshes of the Mediterranean coast, and Berrow is apparently its most northerly station. Here it is reproducing from seed as well as vegetatively. Now that attention has been directed to the plant, it may well be found elsewhere on the coast of Britain—it can easily be passed over as *J. maritimus* or perhaps as a luxuriant *J. gerardi*.

Another rush added to the British list was shown by N. D. Simpson and S. M. Walters (Cambridge). This is *J. bufonius* subsp. *foliosus*, also a native of the Mediterranean countries, which was found in two places in west Cork and one in south Kerry. In the field it is strikingly different from the usual *J. bufonius*, having flowers often more than 1 cm. in diameter with a dark stripe bordering the greenish midrib of the perianth segments and wider leaves which are not setaceous. The seeds also differ, but the Irish material was not sufficiently ripe to check this character.

An undescribed *Sorbus* from the Avon Gorge was shown by E. F. Warburg (Oxford). This has previously been confused with *S. hungarica*. Dr. Warburg also exhibited two forms of *Sorbus pseudofennica* from Arran which are probably distinct apomictic clones. Two well-established aliens were exhibited by H. J. M. Bowen (Harwell). *Geranium pilosum*, a native of New Zealand, was found in Alderney, and *Hydrocotyle moschata*, also from New Zealand, is freely naturalized in Valencia Island, Kerry.

Several very rare plants were found in new localities during the year. One of the most interesting of these is *Lythrum hyssopifolia*, which was found in quantity at Whittlesford, Cambridgeshire, by Mrs. G. Crompton, and which was the subject of an exhibit by D. E. Coombe, F. H. Perring and S. M. Walters (Cambridge). This is at present known to occur regularly only in Jersey, and it has been found in only four other localities in the present century; but revision of the records shows that there has also been some confusion with an allied species sometimes found as a casual. *Lythrum hyssopifolia* is native in central and eastern England, growing in wet open communities. It seems likely that seed may remain viable for long periods and enable the plant to re-appear in favourable seasons. Evidently the persistent wet conditions of 1958 suited it well.

The discovery of another new locality for an orchid, *Spiranthes romanzoffiana*, is also of special interest. This was found by Lough Corrib in Galway by a party collecting records for the Society's Maps Scheme, and a photograph was exhibited by Miss A. K. Harding and Mrs. B. H. S. Russell. The new locality represents a considerable extension of range from those previously recorded in the south and north of Ireland—it seems that this orchid is spreading into new and widely scattered habitats (including western Scotland and Devonshire). The first authentic inland record of *Equisetum variegatum* from the south of England was the subject of an exhibit by E. F. Warburg (Oxford). This horsetail was found by E. G. Arthurs in an old quarry at Cothill, Berkshire; the nearest previously known station is at Weston-super-Mare.

An important new hybrid was shown by P. M. Benoit. This was between *Euphorbia paralias* and *E. portlandica*, with morphological characters convincingly intermediate between the two parents and fruits failing to complete their development. He found it in two places on the coast of Merionethshire. P. M. Benoit also exhibited an interesting series of synthesized hybrids of *Stellaria*. These included *S. media* × *neglecta* (90 per cent), *S. pallida* × *neglecta* (50 per cent), *S. neglecta* × *pallida* (50 per cent) and *S. pallida* × *media* (23 per cent). The percentages indicate the approximate proportions of sterile pollen grains. The following back-crosses were also shown: *S.* (*pallida* × *neglecta*) × *neglecta*, *S. pallida* × (*pallida* × *neglecta*), *S.* (*pallida* × *media*) × *media*. J. A. Ratter (Liverpool) exhibited hybrids of *Spergularia*, and J. P. Savidge (Liverpool) showed specimens of the only naturally occurring hybrid population of *Callitriche* found during his investigation of the genus. This was from Hillerød, Denmark; the pollen was completely abortive, no female flowers could be found, and the likely parentage was *C. platycarpa* × *C. polymorpha* (the hybrid is a triploid with 15 chromosomes).

Several exhibits demonstrated new work using modern techniques on critical groups. C. D. K. Cook (Cambridge) showed specimens of *Ranunculus tripartitus* from the Lizard and *R. lutarius* from the New Forest, and clones which he had grown from these. These clones are virtually impossible to distinguish in summer; but differences can be detected when they are in their winter state. All attempts at inducing capillary leaves in plants which lacked them have proved unsuccessful. M. C. F. Proctor (Exeter) exhibited a careful study of the characters and habitat variations of *Ulex minor* and *U. gallii*, with maps showing their distribution in Britain and abroad. The two species have been much confused, but appear to be distinct. E. W. Davies (Bristol) is working on *Asparagus*. *A. officinalis* subsp. *officinalis*, the cultivated form, is diploid, while the wild plant from the Lizard, subsp. *prostratus*, is tetraploid ($2n = 40$). A study of the latter on the Lizard peninsula showed that at three localities female plants were at least three times as abundant as male and were morphologically distinct. B. T. Styles (Oxford) demonstrated progress made in work on the species problem in *Polygonum* Section *Avicularia*. Trampling and the situation of the habitat have a considerable influence on the different forms the plants take, but those to which the names *P. aequale* ($2n = 40$), *P. aviculare* s.str. ($2n = 60$) and *P. rurivagum* ($2n = 60$) are at present applied appear to be morphologically distinct. Other exhibits concerned with variation included: pink-flowered *Calystegia*, R. K. Brummitt (Liverpool); *Juncus articulatus*, J. R. Cullen (Liverpool); *Mentha* × *dumetorum*, R. M. Harley (Oxford); *Valeriana officinalis*, C. L. A. Leakey (Cambridge); and *Melampyrum pratense*, A. J. E. Smith. T. D. V. Swinscow showed a living plant which was a descendant, through an unknown number of generations, of the variety of *Dryopteris dilatata* described by T. Moore in 1859 as var. *lepidota*. The plant is a tetraploid ($n = 82$) as is usual with the species in Britain, but morphologically it is perfectly distinct. Moore regarded it as of native origin, but evidence of this is obscure.

Much of the effort of British botanists in the field during 1958 was devoted to collecting records for the Distribution Maps Scheme. This was the final season for data to be incorporated in the atlas, and a map was exhibited to show the distribution by squares of the records received. This showed that there are now no major gaps—in the whole of the British Isles only about thirty of the approximately 3,500 10-kilometre squares of the extended National Grid remain unvisited; ten of these are in Ireland and the remainder mainly in the Outer Hebrides and outlying islands of the Orkneys. In England the average number of records per square is about 400, in Wales 300, in Scotland nearly 200, and in Ireland about 150. The total number of records should exceed 1¼ million. A specimen volume with sample maps and overlays was exhibited to indicate the form the published atlas will take. This may not be available for another two years, but in the meanwhile work will continue on special problems, for which members will be invited to contribute data.

An exhibit of some interesting plants from the British herbarium of the British Museum (Natural History) included a series of *Bromus* with several species not well understood by workers in Britain. From the herbarium of the Royal Botanic Gardens, Kew, there were specimens of species believed to be now extinct in Britain. This exhibit was prepared by the late R. A. Graham, who also showed four 'legendary' British orchids (*Serapias neglecta, Calypso bulbosa, Limnodorum abortivum* and *Orchis pallens*) with a review of the records and evidence. E. S. Edees and K. M. Goodway (Keele) directed attention to salt-marsh plants growing in Staffordshire. These were first brought to notice by Robert Plot in 1686, and at least ten species still occur. Salt deep in the Keuper Marl is brought to the surface by springs, and at least seven areas with salt-marsh plants have been found during the present century. Since these populations are more than fifty miles from the coast, and are likely to have been isolated from the coastal populations for several thousand years, they deserve experimental investigation. F. Rose and Miss P. A. Hitch (Bedford College) demonstrated work in progress on the distribution of *Chrysosplenium oppositifolium* and *C. alternifolium* in south-east England, and experimental work with the object of endeavouring to determine what chemical factors, if any, may be responsible.

Exhibits concerned with alien plants were more numerous than usual as these were particularly invited. Wool aliens were shown by Miss C. M. Goodman, J. G. Dony and J. E. Lousley, while Mrs. H. N. Clokie (Oxford) exhibited specimens from the Druce herbarium of interest in connexion with the published work[6] of Miss I. M. Hayward and G. C. Druce on this group of aliens. Miss R. M. Barnes (Norwich Castle Museum) showed specimens and photographs from a Suffolk tannery where sheep skins imported from many countries are processed. Other exhibitors provided aliens of garden origin, or brought in with grain, or of special habitats like refuse heaps—some of the species shown are now well established, and others likely to become so. An example of this was *Erinus alpinus*, which D. P. Young found associated with a native arctic–alpine flora near Bettyhill, Caithness.

There were several displays of excellent colour-slides, including a fine series shown by the National Trust for Scotland of arctic–alpine plants on Ben Lawers. Postage stamps with pictures of plants of interest to botanists were shown by Mrs. A. N. Gibby. The exhibit illustrating the junior meeting at Banyuls in the Pyrenees at Easter 1958 was a reminder of the work the Society undertakes for students.

From the Society's 1958 exhibition it would appear that progress in adding to the knowledge of the British flora was less spectacular than it has been recently. Important additions were less than the average of the past thirty years, and exhibits based on sound research work less numerous. Variations in the interest of exhibits must inevitably arise from year to year, and the fact that 1958 was not a good one is not necessarily an indication that there has been any decline in the activity of British botanists. In view of the great handicap to serious field work imposed by inclement weather throughout the season it is surprising that they have achieved so much.

LINEAR TRANSFER OF A POTENTIALLY MUTANT STATE IN BACTERIA

By Dr. F. KAUDEWITZ
Max-Planck-Institut für Virusforschung, Tübingen

BY observing the pattern of expression shown by reversions from auxotrophy to prototrophy, induced by ultra-violet light, a new type of mutation delay in bacteria has been found. The strain used was the lysin-deficient lys-1 of *Salmonella typhimurium* isolated by E. Witkin. Until about 50 hr. after induction by ultra-violet irradiation the reversions of lys-1 to prototrophy are extremely sensitive to temperature: incubation below 34° C. gives optimal yields, above 36·5° C. reversions were not found (Fig. 1).

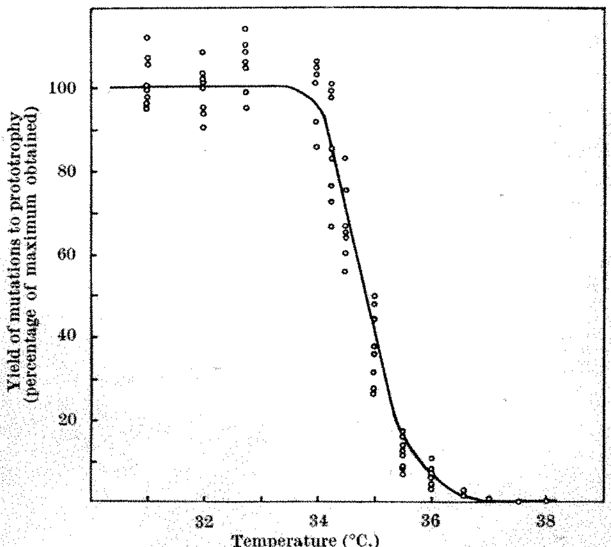

Fig. 1. Yield of mutations induced by ultra-violet light irradiation to prototrophy of strain lys-1 of *Salmonella typhimurium* as a function of incubation temperature

The growth-curve of lys-1 cells irradiated with ultra-violet light so as to yield a survival-rate of 10 per cent and plated on minimal-agar enriched with 0·05 per cent nutrient broth (Fig. 2, curve *a*) shows that cell division begins after a lag-period of about 3 hr. After incubation at 34° C. for 4 days, prototrophic colonies appear each of which represents an independent mutation. Newcombe's technique of re-spreading at intervals after plating[1] provides a method for estimating the number of cells potentially capable of reverting afterwards to stable prototrophs. Fig. 2, curve *b* demonstrates that the increase in such cells starts 5 hr. 40 min. after plating, that is, 2 hr. 40 min. later than the increase of non-mutated cells. From 5 hr. 40 min. to about 7 hr. the curve of increase of these potential reversions (Fig. 2*b*) and the growth-curve of lys-1 cells not induced to prototrophy (Fig. 2*a*) have the same slope.

At about 7 hr., however, there is a sudden break in the curve of increase. Thereafter, this curve is concave even though the results are plotted on a semi-logarithmic scale. The deviation from linearity can be explained by the fact that the reverted clones are inhomogeneous with respect to their growth-characteristics. Re-spreading favours selection of fast-growing types. Thus the later re-spreading is carried out the higher will be the percentage of fast-growing colonies obtained (scheme Fig. 2*c*). Hence, at about 7 hr. the slope of the curve of increase mainly results from the multiplication of slow-growing clones; at about 25 hr. the slope depends almost entirely upon the multiplication of fast-growing colonies.

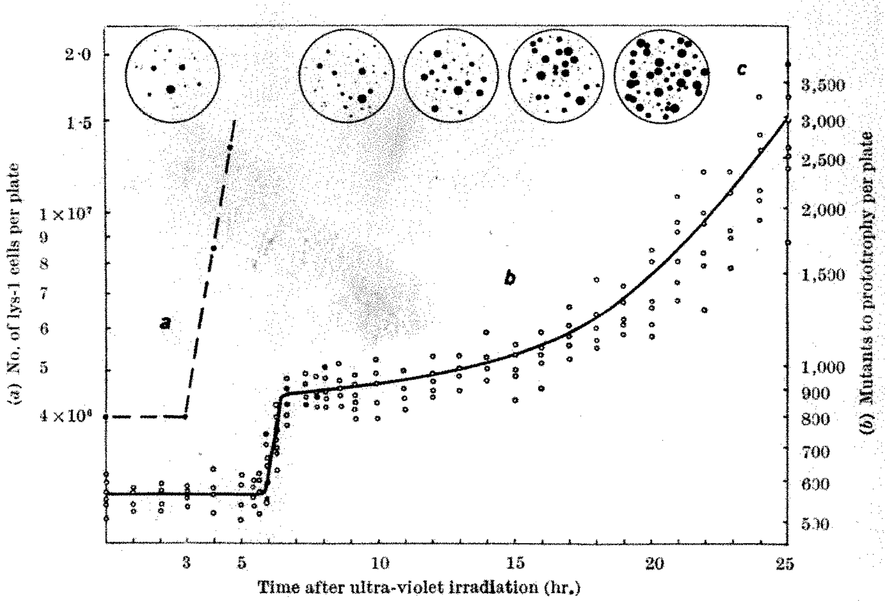

Fig. 2. Relation of potential mutation to prototrophy to time of re-spreading after induction by ultra-violet light. *a*, Growth curve of surviving cells: *b*, number of cells/plate capable of giving rise to prototrophic colonies; *c*, scheme of appearance of plates

The delay in the increase of mutated cells observed after irradiation might be caused by: (1) the temporary formation of filaments which afterwards break up (Fig. 3); (2) a prolonged lag-phase in the mutated cells; (3) the segregation of genetic units, for example, separation of a mutated nucleus from unchanged ones; (4) the linear transfer of the character 'mutated' or 'potentially mutated' to one of two daughter-cells.

The first-mentioned possibility was disproved by the results of experiments in which cell-suspensions obtained by washing plates 5 hr. 10 min. after plating were centrifuged and filtered. No difference was found between the percentage of potential mutants present in the pellet and in the supernatant or present

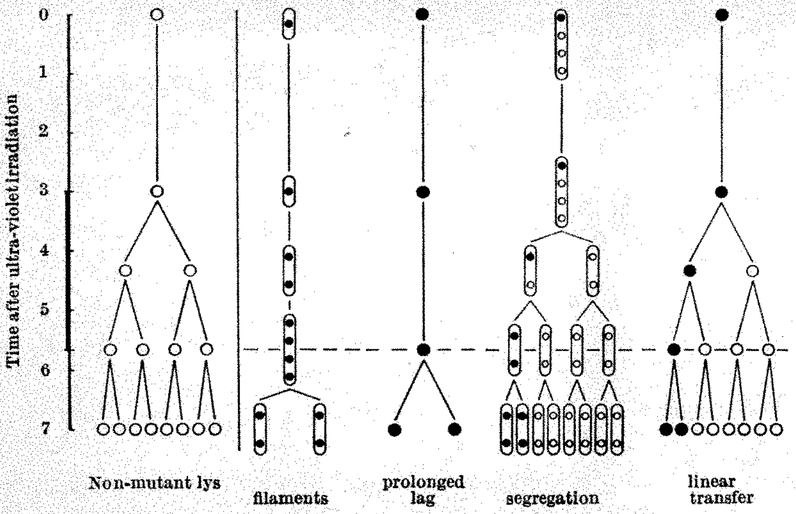

Fig. 3. Mechanisms which might cause a delay in the increase of cells mutated to prototrophy observed from 3 hr. to 5 hr. 40 min. after ultra-violet induction (cf. Fig. 2)

in the filtrate and on the filter. The existence of a prolonged lag-phase after plating, as suggested in hypothesis 2, would imply that membrane synthesis in potentially mutated cells is much less effective than in non-mutated cells. Were this the case the percentage of cells in both categories killed by a given dose of penicillin would be different. Experimental results[2], however, have demonstrated that during the time-interval 3–5 hr. the same percentage of potentially mutated and non-mutated cells were killed by a comparable dose of penicillin. This finding indicates that potentially mutated cells do not have a prolonged lag-phase. The third hypothesis, namely, a segregation of genetic units, would require a minimal number of cell divisions for the expression of the recessive phenotype of a mutant. Therefore, a prolongation of generation-time would result in a postponement in the increase of mutated cells. To test this hypothesis aliquots of cells irradiated by ultra-violet light were placed on enriched or minimal medium (Fig. 4). The growth-curves of non-mutated cells obtained with the two media have different slopes, indicating a different time between cell-divisions. However, on both media, as shown with the re-spreading technique, the increase in the number of mutants starts at exactly the same time, that is, at 5 hr. 40 min. after plating. Thus the segregation hypothesis is disproved.

The hypothesis of linear transfer of character 'reversion' assumes the concurrence of a potentially mutant state which is transferred in a linear order to only one of the offspring of an affected cell. To test this thesis experiments were carried out using the chequerboard technique of Witkin and Thomas[3]. This method yielded clonal offspring of the irradiated cells. Assuming linear transfer it would be expected that at any time before 5 hr. 40 min. each clone derived from a potentially mutated cell would contain only one mutated cell, but many non-mutated cells. At 7 hr. and later, however, there should be in such a clone at least two cells which give rise to prototrophic colonies. This actually was found (Fig. 5). The delay of the increase in number of potentially mutated lys-1 cells after irradiation by ultra-violet light was proved by this finding to be due to linear transfer of the potentiality to express the prototrophic character.

To solve the problem of what kind of material transfers this potentiality, experiments still in progress add the following evidence: while about 10 per cent of reversion strains can serve as donors in transduction of lys-1 to prototrophy, 100 per cent of reversion strains (after infection) give rise to phages which transduce all wild-type markers of strain lys-1. By transduction analysis the transducible reversions were shown to be due to suppressors at loci other than the mutational site of lys-1. In early stages of their origin all lys-1 reversions, transducible or not, show the same degree of temperature sensitivity and linear transferability. From this it may be concluded that all lys-1 reversions have the same basic mechanism of origin. Why, then, are some of them transducible, and others not? The results of experiments in which X-irradiation was applied to transducing phages synthesized in different

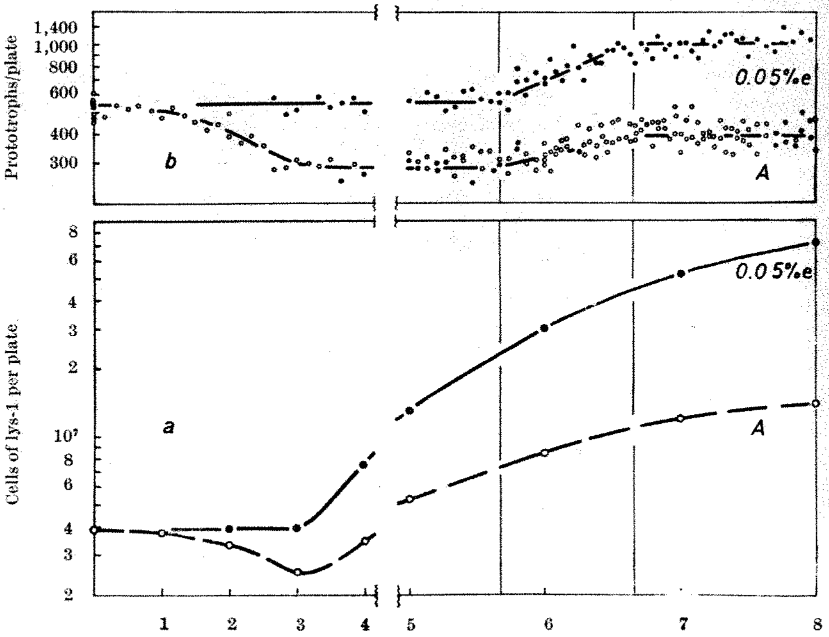

Fig. 4. Lack of dependence of time of increase in potential mutants of prototrophy upon rate of growth of cells surviving after ultra-violet light irradiation. *a*, Growth curves of surviving cells on minimal agar (*A*) and minimal agar enriched with 0·05 per cent broth; *b*, number of cells/plate capable of giving rise to prototrophic colonies on either medium

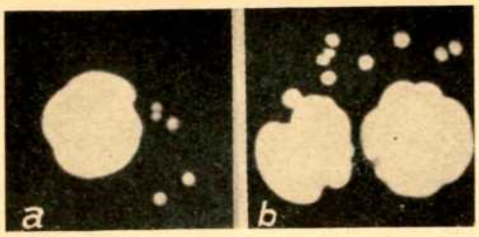

Fig. 5. Results of clonal re-spreading (using the chequer-board technique of Witkin and Thomas) of lys-1 cells potentially mutated to prototrophy. *a*, Re-spreading at 5 hr. 20 min. after ultra-violet induction: the clone was composed of 5 non-mutated microcolony-forming cells and only one cell capable of giving rise to a macrocolony; *b*, re-spreading at 7 hr. after ultra-violet induction: the clone was composed of 9 non-mutated microcolony-forming cells but two cells capable of giving rise to macrocolonies

strains of transducible reversions indicate target sizes which were often larger than one gene-locus. This observation led to the conclusion that the suppressors are non-intragenic changes. They represent translocations of chromosomal segments which in most strains of reversions are too big in size to be incorporated into phage.

The same temperature sensitivity and linear transferability and the rare occurrence of transducibility were shown by reversions arising spontaneously of lys-1 and by reversions of 17 of 134 auxotrophic mutants of *Salmonella typhimurium* and *E. coli*. Thus the phenomena are not unique to strain lys-1.

From the experimental results presented the following working hypothesis is formed. By the mutational event, part of the genetic material may become separated from the chromosome. Without duplication it is transferred by each cell-division for some time in a linear order. Its re-incorporation may lead to a variety of changes in chromosomal architecture which function as non-intragenic suppressors to cause different degrees of prototrophy.

A detailed account of this work will be published in the *Zeitschrift für Vererbungslehre*.

LIQUID CRYSTALS OF LIPID IN NORMAL AND ATHEROMATOUS TISSUE

By G. T. STEWART

Medical Research Council Laboratories, Carshalton, Surrey

THE chemical composition of the extractable lipids in atherosclerotic lesions is well known, but much less is known about the physico-chemical forms in which the lipids gain access to, and exist in, these lesions in the body. Poole and Florey[1] have shown how sudanophilic fat first appears in the aortic intimal deposits of atheroma in the cholesterol-fed rabbit, and have demonstrated the presence of lipoid-laden macrophages on the endothelial surface. Their observations do not support the idea advanced by Rannie and Duguid[2] that lipid is incorporated into the atheromatous lesion when endothelium overgrows adherent clumps of these macrophages. Sudanophilic fat can be demonstrated in endothelial cytoplasm in areas of intima where no macroscopic deposition of atheroma is visible and where no macrophages are present.

One difficulty which constantly limits work in this field is the fact that microscopy is usually performed upon tissues which have been physically altered, especially with regard to lipid distribution, by fixation, freezing or embedding, and staining. The Oxford workers (Florey *et al.*) have overcome this difficulty so far as circulating cells are concerned by inserting ear-chambers into cholesterol-fed rabbits and have thereby demonstrated that, under experimental conditions, birefringent lipid may be present intracellularly in macrophages[3]. In the studies described below, an attempt is made to examine atherosclerotic and normal tissues and plasma in the fresh state, and at temperatures approaching 37° C. to compare the lipids seen under such conditions with those viewed in conventionally processed tissues. It is thought that the results may have some bearing on the problem of the integration of certain forms of lipid in tissue.

Microscopic Identification of Lipid in Fresh Tissue

When frozen sections of unfixed atheromatous vessels from humans or from cholesterol-fed rabbits are examined by conventional techniques, various forms of lipid besides sudanophilic fat can be detected microscopically including, in unstained frozen sections or films, crystals of fatty acid, free cholesterol and amorphous birefringent material (Fig. 1). A few spheroid objects of diam. 0·5–5μ with a cross or other interference pattern on polarization ('spherulites')

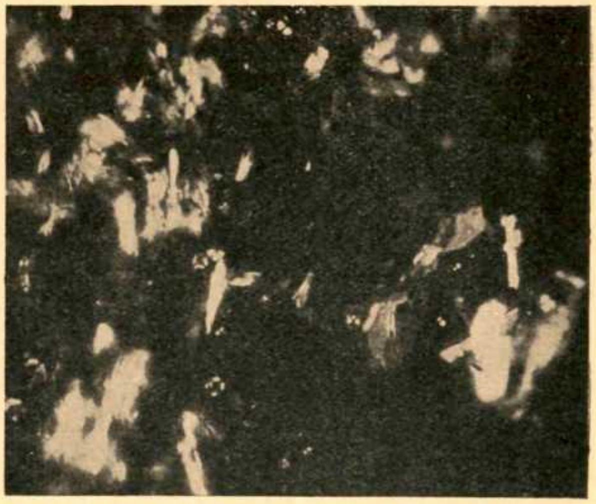

Fig. 1. Film made after freezing from an atheromatous deposit in a cholesterol-fed rabbit. Crystals of fatty acid and free cholesterol, amorphous material and a few spherulites are present (× 400, polarized light)

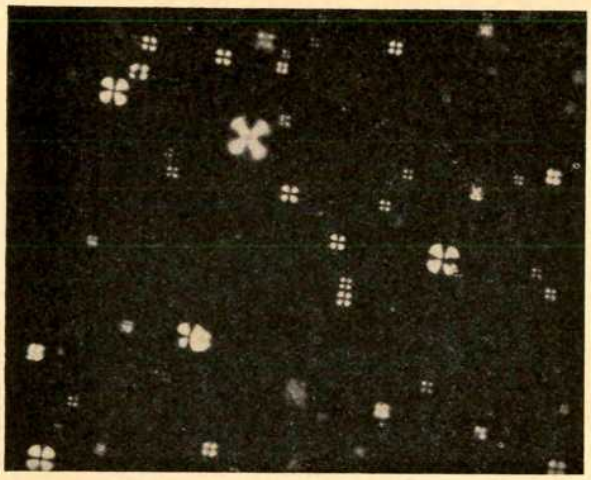

Fig. 2. Film made at 37° C. and photographed at room temperature from an atheromatous deposit in a cholesterol-fed rabbit. The birefringent material consists almost entirely of spherulites (× 400, polarized light)

may also be seen but are never numerous and may be absent in sections viewed soon after freezing.

A very different picture is obtained when fresh preparations are made at 24–37° C. in distilled water or other inert medium from the warm aortic lesions of a cholesterol-fed rabbit which has just been killed. Under such conditions, the intimal deposits are in a semi-liquid state and show, in microscopic films, a predominance of spherulites of diam. 0·5–2·0μ, especially in the superficial layers (Fig. 2). These spherulites, though varying slightly in size, are uniform in shape and interference figure when viewed immediately under polarized white or monochromatic light. Some minute birefringent, ovoid or amorphous particles may also be present; but the true crystals of free cholesterol and fatty acids seen in frozen sections are not visible. On cooling to room temperature, these crystals begin to form slowly, though the spherulites persist. Rapid cooling to 4° C. causes disintegration of many of the spherulites. At −10° to −20° C., this disintegration is practically instantaneous and complete. The spherulites are soluble in fat solvents and show no sudanophilia, though amorphous sudanophilic material is present in films of fresh, warm tissue as in frozen sections. The addition of digitonin (0·5 per cent in 50 per cent alcohol) causes gradual disappearance of the spherulites, with replacement by amorphous and crystalline precipitates.

Spherulites similar to the above are present also in some normal tissues, intra- and extra-cellularly, when scrapings or imprint preparations are made from fresh, wet tissue. They are conspicuous in myelin from the white matter of brain and spinal cord, and may be prominent in the adrenal cortex as well as in the ovaries and secretory endometrium of women of child-bearing age. Spherulites may also be found in testis and semen. In myelin, the optical interference figure of the spherulites may not be greatly altered by freezing or formol-fixation, though in other tissues, spherulites may disappear on freezing and reappear gradually at 24–37° C. Spherulites are not present in normal adipose tissue.

Identification of Lipid Particles in Plasma

Particulate lipid in plasma is usually seen in the form of chylomicrons under dark-ground illumination. These particles, composed largely of triglyceride, are mainly isotropic in plasma examined in the state of normal alimentary lipæmia. In healthy human and rabbit plasma, few, if any, anisotropic particles are present.

In plasma from rabbits fed on cholesterol, anisotropic particles can be found regularly in films made immediately from the meniscus after low-speed centrifugation. These particles comprise spherulites, comparable in size and appearance with those observed in tissue, and minute ovoid or stellate objects, of chylomicron-size, but strongly birefringent. Both types of particle are present extracellularly.

Intravenous injection of sulphated polysaccharides (for example, heparin 100–500 units/kgm.) under conditions already described[4] causes a temporary aggregation of particulate lipid in plasmas, sampled 3–30 min. after injection. Low-speed centrifugation of plasma in this state, carried out at 37° C., causes an opaque pellicle loaded with spherulites and amorphous (isotropic) lipid to separate at the meniscus (Fig. 3). Ultracentrifugation of this plasma at room temperature, adjusted according to the technique of de Lalla and Gofman[5] to a mean density of 1·063 gm./ml. at a mean centrifugal force of 79,420g,

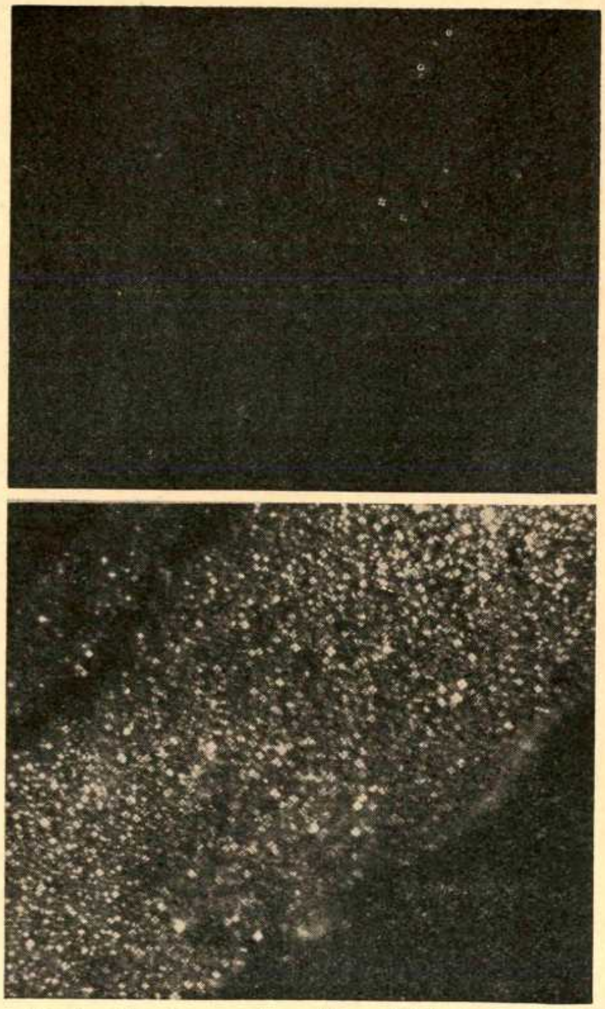

Fig. 3. Films from meniscus of hypercholesterolæmic rabbit plasma after low-speed centrifugation. Above, before injection: a few spherulites are present; below, after heparin 100 units/kgm. intravenously. A pellicle of identically orientated spherulites is present (× 100, polarized light)

causes the spherulites to separate in the low-density layer, in association with lipoproteins of hydrated density 1·00–1·04 gm./ml. This separation occurs within 5 hr. in the ultracentrifuge and serves to indicate the density of spherulites of average size, but does not effect a concentration comparable to low-speed centrifugation at 24–37° C. after the injection of heparin.

Similar spherulites and ovoid particles can sometimes be found, cell-free, in abnormally lipæmic human plasma by the same technique. None has so far been found in normal plasmas of children and adults; but small numbers (of the order of 3–6 in a cover-slip film) have been found in the low-density layer of ultracentrifuged plasmas from three adult males with essential hyperlipæmia and two children with nephrotic hyperlipæmia.

Properties of Spherulites in Tissue and Plasma

In preparations kept at 24–37° C., the spherulites show crystal-like growth, partly as discrete globules, partly as confluent masses. Cooling prevents this growth and provokes true crystallization of fatty acids and steroid rhombs. At 37° C. in glycerol, the larger globules show complex radial and concentric interference figures and a display of polarization colours in convergent white light. The interference figure is altered in accordance with the sign of birefringence when a quarter-wave plate is inserted into the optical system.

When films of plasma or tissue are examined immediately at 37° C., without cooling, the spherulites show a more fluid consistency. The globules are elongated or wavy in outline, and may be larger and confluent (Fig. 4). The interference figure is still discernible, though deformed, within the globule, but no polarization colours are seen. Extinction of the polarized beams leaves the globule with greenish droplet-like refractility in white light.

Possible Significance of these Observations

It is obvious that the spherulites and some of the accompanying ovoid particles here described belong to the liquid phase of tissue, and show crystalline properties while still in a state of 'flow' in plasma and cells at or slightly below body temperature. Such particles possess, therefore, the essential properties of 'liquid crystals', a term first used by Lehmann in 1889[6] to describe the intermediate paracrystalline form of some pure organic substances. Such crystals, now well recognized in various physical systems[7,8], especially where esters, soaps and cholesteric substances are present[9], have received little attention in biology.

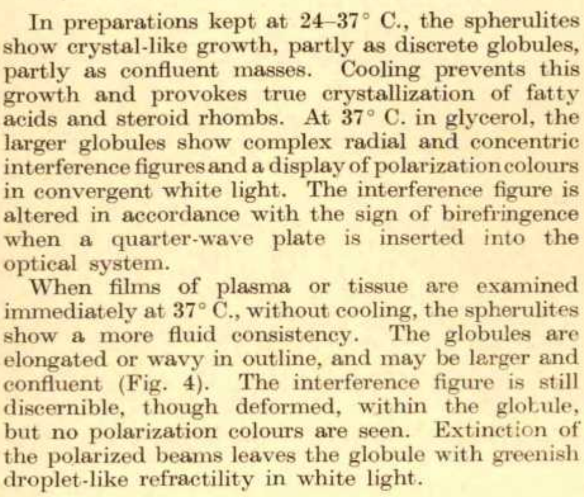

Fig. 4. Film from meniscus of hypercholesterolæmic rabbit plasma after intravenous injection of heparin 100 units/kgm. Whole experiment, including photograph, performed at 37° C. The spherulites are in a state of flow with wavy outlines (× 400, polarized light)

The liquid crystalline form can occur when there are aggregates of systematically orientated molecules of birefringent substance[10]. At a certain temperature, the solid goes into a turbid phase, which is both birefringent and fluid. In this mesomorphic state, the molecules are maintained in stable orientation by specific polar groups and unspecific van der Waals attractions[11]. Alterations in temperature and other physical stresses disrupt the relatively weak intramolecular forces of cohesion, with loss of birefringence, specific interference figures and fluidity.

The liquid crystals here identified in plasma and tissue are stable at, or slightly below, body temperature. Some of their properties—the type of true crystallization on cooling, the development of iridescent polarization colours and complex interference figures on growth—are consistent with the presence of cholesterol esters together with other non-sudanophilic lipids in their structure. It is likely that some of the birefringent material observed in adrenal cortex by Yoffey and Baxter[12] and in circulating macrophages by French[3] is of a similar type. When viewed in fresh tissue, all the birefringent particles are of chylomicron size, or slightly larger, and these presumably represent the natural nuclei from which further paracrystalline growth proceeds in older preparations.

In the plasma colloid, the spherulites and ovoid particles appear to be associated mainly with the macromolecular lipoproteins of lowest density. In some normal tissues—though not to any significant extent in adipose tissue—closely related if not identical particles are present physiologically, while, under pathological conditions, similar particles form a major component of atheromatous substances in the liquid state. The occurrence of the liquid crystalline form indicates that such particles, unlike other forms of physiological and pathological lipid, possess internal cohesive forces which confer stability and may influence their distribution and retention in tissue. The high concentration of spherulites found in the intima of atherosclerotic vessels, together with their association with the low-density lipoproteins of abnormally lipæmic plasmas, suggest that lipid in this form plays a part in initiating and maintaining the atheromatous deposit.

TRICHLORACETIC ACID-INSOLUBLE PHOSPHATE COMPOUNDS IN CARTILAGE

By R. G. WHITEHEAD and Dr. S. M. WEIDMANN

Biological Research Unit, Dental School and Hospital, University of Leeds

IN a previous communication, we[1] gave the analysis of phosphate compounds in the fraction of cartilage soluble in trichloracetic acid, and found that both adenosine triphosphate and orthophosphate had a high specific activity of incorporated phosphorus-32 when the latter was injected intraperitoneally. The acid-insoluble phosphate compounds have not hitherto been studied in detail.

Dallemagne[2] showed that as a young animal grows older the calcium/phosphorus ratio of ashed cartilage rises until the ratio of tricalcium phosphate is reached. Refuting the theory that the low calcium/phosphorus ratio was due to the primary precipitation of dicalcium phosphate, it was suggested that the phosphate present in excess of that required for a calcium/phosphorus ratio of 1·94 was attached to the organic element afterwards to be hydrolysed when the requisite calcium ions were available for deposition of tricalcium phosphate. In the light of this theory, it was of interest to investigate the matrix-bound phosphate compounds of cartilage.

In preliminary work it was shown that although an upward gradation with age of calcium/phosphorus ratios occurred in the ashed epiphyseal cartilage samples, in the fraction soluble in trichloracetic acid the ratio was always 1·9–2·1, indicating that a compound of the tricalcium phosphate type was always deposited even in the earliest phases of calcification. The phosphate compounds remaining in the acid-insoluble fraction were further analysed by the method described by Heald[3] for similar compounds in brain.

The phospholipid was extracted with chloroform–methanol 2 : 1 (v/v) at 0° C., and the nucleic acids using urea dissolved in a saturated solution of sodium chloride and ammonium sulphate at 100° C. The nucleic acids were afterwards precipitated from this extract as their copper salts. The residue remaining after the extraction of phospholipid and nucleic acid was incubated in 1·0 *N* potassium hydroxide for 18 hr. at 37° C., then 0·2 vol. of 6·0 *N* hydrochloric acid and 0·5 vol. of 10 per cent (w/v) trichloracetic acid were added. The resultant small precipitate together with the remainder of the undissolved organic material were removed by centrifugation. The supernatant was examined for organic and inorganic phosphate by the method of Berenblum and Chain[4]. The inorganic phosphate is produced by the alkaline hydrolysis of phosphoprotein and is of significant importance in brain metabolism. The organically bound phosphate of this fraction is of unknown structure.

The composition of the acid-insoluble phosphate compounds obtained from five litter-mate puppies (3 weeks old) are given in Table 1. It will be observed that no phosphoprotein was detected (in which respect cartilage differs from brain). The concentration of nucleic acid phosphate, the 'unknown organic phosphate' fraction and the acid-insoluble residual phosphate are quite similar to those found by Heald[3] in brain. There is also present a considerable proportion of phospholipid.

Table 1. DISTRIBUTION OF PHOSPHORUS COMPOUNDS IN THE TRICHLORACETIC ACID-INSOLUBLE FRACTION OF EPIPHYSEAL CARTILAGE

The results represent the mean values ± *S.E.M.*

Fraction	No. of animals	Concentration (mgm. P/100 gm. wet wt.)
Phospholipid	5	10·5 ± 0·3
Nucleic acid	5	6·6 ± 0·9
Phosphoprotein	5	None
'Unknown organic phosphate'	5	6·9 ± 0·9
Residue	5	1·53 ± 0·03

In some experiments 330 μc./kgm. of phosphorus-32 was injected intraperitoneally into young kittens and the animals killed 2 hr. later. In Table 2 the specific activity of incorporated phosphorus-32 in the phospholipid, nucleic acid and 'unknown organic phosphate' fraction is compared with the values for adenosine triphosphate. In relation to the adenosine triphosphate the turn-over of these trichloracetic acid-insoluble compounds is very low (Table 2).

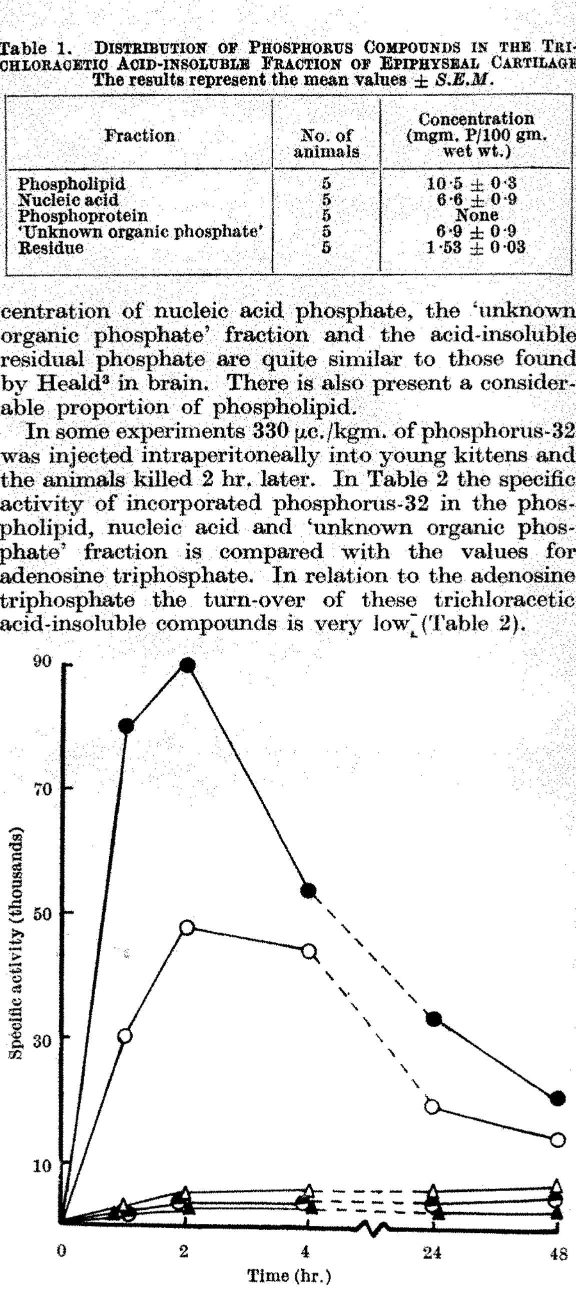

Fig. 1. Specific activity – time relationship for various phosphate compounds in ossifying cartilage, taken from litter-mate puppies, aged 21 days. For definition of specific activity see Whitehead and Weidmann (ref. 6)

●, Orthophosphate; ○, adenosine triphosphate; △, phospholipid; ◓, nucleic acid; ▲, 'unknown organic phosphate' fraction

Table 2. SPECIFIC ACTIVITY OF VARIOUS PHOSPHATE COMPOUNDS IN EPIPHYSEAL CARTILAGE FROM 3-WEEK-OLD KITTENS, MEASURED 2 HR. AFTER THE INJECTION OF PHOSPHORUS-32
Results represent mean values ± *S.E.M.* For definition of specific activity, see Whitehead and Weldmann (ref. 6)

Phosphate compound	No. of animals	Specific activity
Adenosine triphosphate	45	24,800 ± 940
Phospholipid	6	1,000 ± 60
Nucleic acid	6	2,430 ± 280
'Unknown organic phosphate' fraction	6	2,370 ± 160

The results presented strongly suggest the idea that the 'excess' phosphate was temporarily bound to the matrix prior to its deposition as bone salt to be incorrect. It seems probable these phosphate compounds are only part of the normal cell constituents. If part of this phosphate were concerned in a cyclic transfer system from acid-soluble phosphate esters, a close relationship between the magnitude of turn-overs in the two types of compound would be expected; but this is not the case. The latter point was confirmed by a study of the time relationship for the incorporation of phosphorus-32 into the various phosphate compounds. The results (Fig. 1) show the three acid-insoluble compounds exhibit only a slow incorporation of isotope similar to that observed in other tissues, while the adenosine triphosphate has a marked peak at 2–4 hr., and even after 48 hr. has a considerably higher specific activity than the insoluble compounds.

Cartier and Picard[5] suggested that adenosine triphosphate stimulated calcification in cartilage by forming a primary seed, after which bone salt crystallized out automatically on to the seed, and recent work by us[6] has produced evidence in support of this idea. If the seeding effect of adenosine triphosphate is achieved by the phosphorylation of the matrix, as Cartier and Picard[5] have suggested, then the seed should be highly labelled. It would appear that owing to the absence of any highly active component in the acid-insoluble fraction, these compounds do not participate in the seeding mechanism, which one would expect to be a rapid reaction. The considerable loss of tracer after 2–4 hr. in the cartilage orthophosphate of bone salt (Fig. 1) indicates that a fast resorption and redeposition of new bone salt is occurring. It is unlikely that such a rapid reaction could be stimulated by a slowly synthesized phosphate compound.

DiStephano, Neuman and Rouser[7] characterized an acid-insoluble phosphate compound in cartilage which they suggested may play a part in the calcification mechanism. Presumably this compound would be contained in the 'unknown organic phosphate' fraction; but again the absence of any appreciable activity in this fraction indicates the doubtful importance of this ester in calcification.

It would appear that if adenosine triphosphate is essential in the epitactic stimulation of calcification, then this must be achieved either by the formation of a labile acid-soluble seed or as a result of its high energy content. The acid-insoluble phosphate compounds appear to be of little significance in the rapid endochondral calcification of cartilage.

This work has been supported by a grant from the Medical Research Council.

PREALBUMIN AS A COMPLEX IN THE α-GLOBULIN FRACTION IN HUMAN SERUM

By DR. J. R. TATA*
National Institute for Medical Research, Mill Hill,
London, N.W.7

THE thyroid hormone is normally transported in the blood in association with the 'thyroxine-binding protein', the principal characteristic of which is an electrophoretic mobility on filter paper or in the moving boundary system intermediate between those of α_1- and α_2-globulins[1,2]. This protein fraction can also be concentrated in the fractions of human serum rich in α-globulin submitted to ethanol precipitation or passage through ion-exchange resins[3]. However, experiments with a recently devised non-electrophoretic method for comparing the thyroxine-binding affinities of different proteins[4] showed human serum prealbumin (as isolated by Schultze *et al.*[5]) to have a more intense interaction with thyroxine than other serum proteins. In this connexion it has been shown lately that thyroxine, added to normal human serum, migrated with the prealbumin fraction in starch gel electrophoresis[6], and that a part of the added thyroxine could be made to migrate with the prealbumin fraction even in paper electrophoresis if a fraction rich in prealbumin were added to whole serum[7]. These results have been interpreted by Ingbar[7] to mean that thyroxine-binding protein and prealbumin are two distinct proteins which bind thyroxine, each possessing a high affinity for thyroxine; these are in addition to human serum albumin, which is a secondary binding protein, effective in serum only at higher concentrations of thyroxine. However, the results outlined below indicate that the thyroxine-binding properties of the α-globulin fraction of thyroxine-binding protein are principally due to prealbumin, present as a complex of unknown composition. In this respect, except for the binding of hæmoglobin by haptoglobins[8], little is known about physiologically significant protein–protein interaction in normal serum[9].

As a first approach, the high tryptophan content of human serum prealbumin[5] was used for detecting it in small amounts on paper by development with Ehrlich's[10] *p*-dimethylaminobenzaldehyde reagent. Prealbumin and the Cohn fractions IV-4 and IV-6 rich in α-globulin were the only serum protein fractions to give a positive tryptophan reaction on spot tests on paper (10–25 μgm.), whereas all the other fractions, including α-globulin (Lister), β-globulin (fraction G-2, Lister), β_1-globulin (Protein Foundation, Inc.) and human serum albumin (Lister), failed to react or only reacted very feebly with Ehrlich's reagent. The results of zone electrophoresis on paper (using conventional horizontal electrophoresis at *p*H 8·6[11] and analysis of thyroxine-binding[2]) are shown in Figs. 1 and 2.

---

* Beit Memorial Fellow.

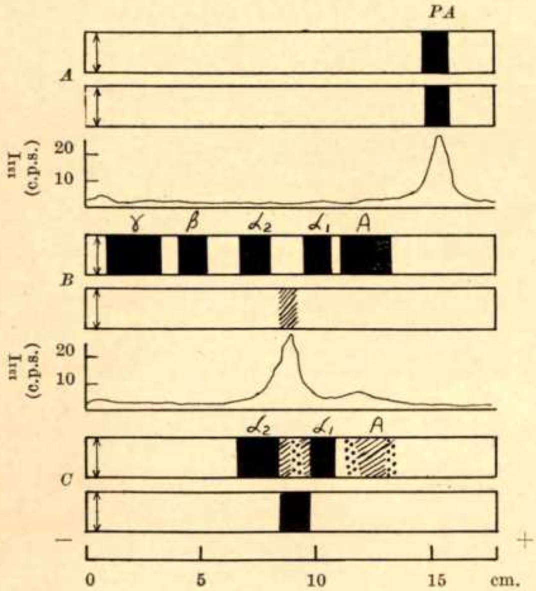

Fig. 1. Paper electrophoretic analysis of (*A*) human serum prealbumin (2·5 mgm./ml.), (*B*) whole human serum, and (*C*) Cohn fraction IV-4 (12·5 mgm./ml.). The upper strip indicates the positions of proteins when stained with bromphenol blue and the lower strip that of the tryptophan-rich protein fraction when stained with *p*-dimethylaminobenzaldehyde for the same sample. Full black areas indicate a strong reaction, hatched lines a moderate one and dotted zones a feeble but positive staining reaction. The curves represent the distribution of radioactivity in electrophoretic pattern if a trace amount of L-thyroxine labelled with iodine-131 was added before electrophoresis. Electrophoresis was performed in 0·075 *M* veronal buffer, *p*H 8·6 at 3·6 V/cm. for 18 hr. Double-headed arrows denote the point of application of samples. *A*, albumin; *PA*, prealbumin

Prealbumin when analysed alone was shown to be a fast-moving protein, using both bromophenol blue and Ehrlich's reagent (Fig. 1*A*), but in electrophoretic patterns of whole serum (Fig. 1*B*) or Cohn fraction IV-4 (Fig. 1*C*) the tryptophan-rich fraction was found in the position occupied by thyroxine-binding protein, namely, between the α_1- and α_2-globulins.

The first indication that human serum prealbumin could form a complex in serum was obtained in experiments in which increasing amounts of prealbumin were added to serum (Fig. 2).

When an amount of prealbumin equal to that used alone (2·5 mgm./ml., Fig. 1*A*) was added to whole human serum (Fig. 2*A*) only a small proportion of it was recovered on electrophoresis as 'free' prealbumin; at the same time, an increase in the material rich in tryptophan in the α-globulin zone was found. Doubling the amount of prealbumin added to the serum (Fig. 2*B*) led to an increased recovery of the original fast-moving component with no concomitant increase in the amount of material rich in tryptophan in the α_1–α_2-globulin zone, suggesting saturation of a possible complex. A qualitatively similar result was obtained when Cohn fraction IV-4 was used instead of whole serum, which further suggested that prealbumin might be associated with an α-globulin component. No such complex formation could be detected with other serum fractions, including human serum albumin (Fig. 2*C*).

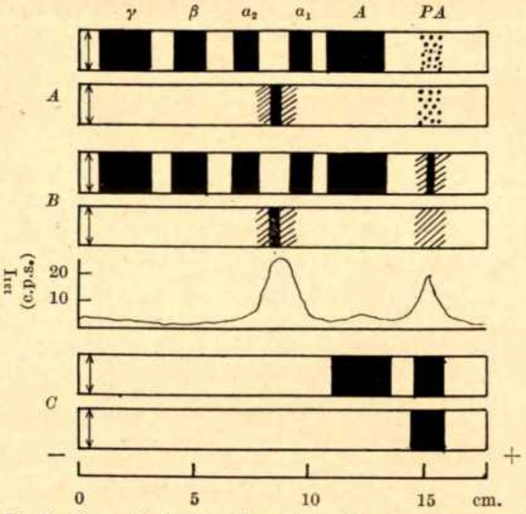

Fig. 2. Paper electrophoretic analysis of human serum to which prealbumin was added to the extent of (*A*) 2·5 mgm./ml., and (*B*) 5·0 mgm./ml. The sample *C* consisted of a mixture of human serum albumin (50 mgm./ml. and prealbumin (5 mgm./ml.). Other details as in Fig. 1

As regards thyroxine-binding, it is noteworthy that when thyroxine labelled with iodine-131 was added to these proteins in trace amounts, it was recovered in the tryptophan-rich zone (Figs. 1 and 2). If more than one zone rich in tryptophan were present (Fig. 2*B*), thyroxine was distributed between the zones in direct proportion to the intensity of the Ehrlich tryptophan reaction. It should be noted that similar distribution of radioactivity was obtained by Ingbar[7] in the paper electrophoretic analysis of thyroxine-binding by serum supplemented with a prealbumin-rich fraction.

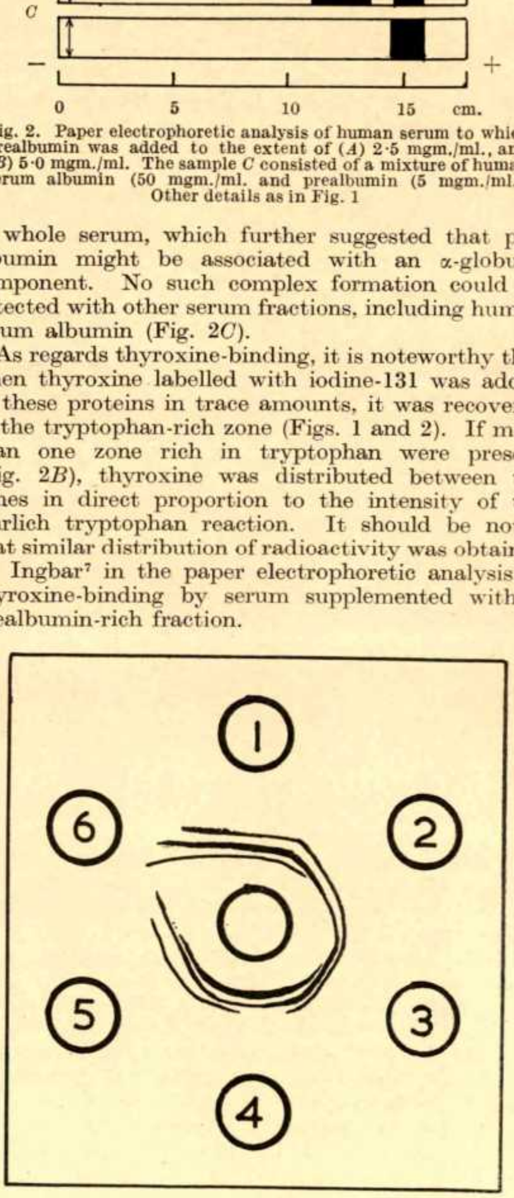

Fig. 3. Interaction between rabbit antiserum against human serum prealbumin (central well) and (1) prealbumin, (2) thyroxine-binding protein eluate from electrophoretic separation of whole serum, (3) Cohn fraction IV-4, (4) ten-fold concentrate of human amniotic liquor, (5) whole human serum, and (6) human serum albumin, according to Ouchterlony's (ref. 12) technique of diffusion in agar gel

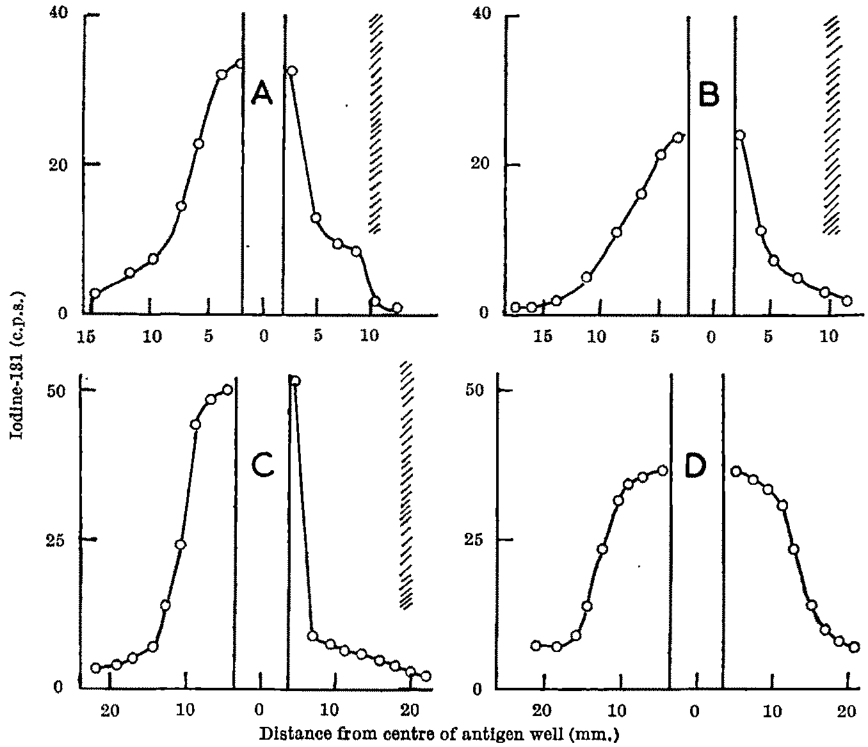

Fig. 4. Distribution of radioactivity in agar gel by a method of profile counting after the immunological reaction has occurred. Thyroxine labelled with iodine-131 was added to all samples tested against rabbit anti-prealbumin antiserum. (*A*) prealbumin (1·0 mgm./ml.); (*B*) whole serum (four-fold dilution); (*C*) thyroxine-binding protein eluate corresponding to 1 ml. of serum; (*D*) human serum albumin (20 mgm./ml.). The hatched bars indicate the position of the precipitate formed after 48 hr. The position of the well containing rabbit anti-human prealbumin antiserum was to the right of the antigen well in the diagram

The second approach to the problem was an immunological one. By using Ouchterlony's[12] technique of diffusion in agar gel (Fig. 3), the following protein fractions reacted with rabbit antiserum against human serum prealbumin to give one or more of the three precipitation lines (depending on the antigen concentration) observed with prealbumin: (*a*) whole human serum; (*b*) Cohn fraction IV-4; (*c*) eluate of thyroxine-binding protein in the α-globulin fraction obtained from whole serum by electrophoresis on a cellulose column[13] (after marking it with a trace of thyroxine labelled with iodine-131); (*d*) a ten-fold concentrate of human amniotic liquor, which also possesses a tryptophan-rich component intermediate between the α_1- and α_2-globulins in paper electrophoresis that exhibits intense thyroxine binding[14]. Human serum albumin (Lister) at various concentrations did not show any reaction with the anti-prealbumin serum under similar conditions.

Finally, strong evidence that one at least of the prealbumins present in thyroxine-binding protein is responsible for the binding of thyroxine was obtained from profile counting of the radioactivity[15] in agar gels after marking the test samples with a trace of thyroxine labelled with iodine-131 (0·03–0·08 μgm./ml.).

In the absence of a reaction with antibody, the distribution of radioactivity on either side of the antigen well is symmetrical, whereas if precipitation occurs the antigen does not diffuse freely on the side of the antibody, so that the profile counts show asymmetry.

As Fig. 4 shows, the pronounced asymmetry found in the distribution of radioactivity after reaction with anti-prealbumin serum indicates that most of the thyroxine in whole serum, in Cohn fraction IV-4 and in eluate of thyroxine-binding protein from whole serum was bound to the prealbumin component. The absence of any accumulation of radioactivity in the zone of the antigen–antibody precipitate can be explained by supposing that the reaction between prealbumin and anti-prealbumin results in the liberation of thyroxine originally bound to prealbumin. Evidence that this does, in fact, occur will be presented elsewhere. The symmetrical distribution of radioactivity and the absence of a precipitation line with albumin (Fig. 4*D*) further demonstrates the lack of prealbumin in this fraction and indicates that albumin binds thyroxine independently of prealbumin.

It is concluded from these experiments that a large part of human serum prealbumin is present as a complex in the α-globulin fraction and that it is responsible for the binding of thyroxine observed in thyroxine-binding protein. Other questions have arisen from this work, such as the identity of the component associated with prealbumin and whether the thyroxine-binding of the complex is greater than that of its individual components. Attempts to resolve these problems and full experimental details will be described elsewhere.

I am indebted to Dr. A. C. Allison for valuable advice and help throughout this investigation. I also wish to thank Prof. H. E. Schultze for generous supplies of human serum prealbumin and immune rabbit serum, Dr. D. R. Bangham for human amniotic liquor and Dr. S. H. Ingbar for Cohn fraction IV-4.

LETTERS TO THE EDITORS

CRYSTALLOGRAPHY

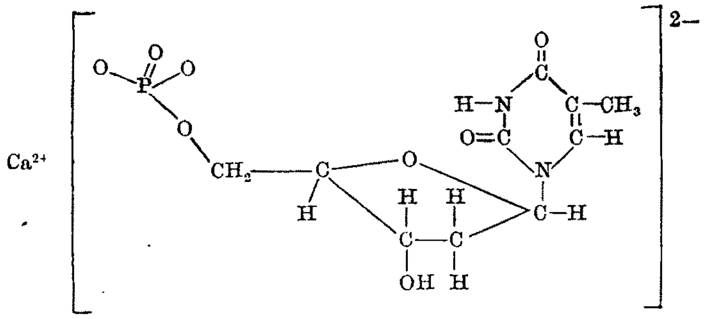
Crystal Structure of Calcium Thymidylate

NUMEROUS recent observations, both biological and chemical, have indicated that deoxyribonucleic acid is very probably the substrate which serves to store and transport genetic information. The initial formulation of this hypothesis brought forth a variety of structural speculations aimed at linking the biological role of deoxyribonucleic acid to its molecular structure. The most interesting and successful model was proposed by Crick and Watson[1]; it has since been supported by many other studies.

However, the success of this model should not be allowed to obscure certain limitations inherent in the stereochemical assumptions of Crick and Watson. They assumed that the elementary units of which deoxyribonucleic acid is composed have essentially the same structure in the entire molecule as in crystals of individual degradation products. At present, the structures of about a dozen purine and pyrimidine bases are known[2-11], and in addition, the structures of two ribosides, cytidine[12] and 5′-bromo-5′-deoxythymidine[13], and one ribotide, adenylic acid[14], have been determined. Spencer[15] has recently emphasized the need for precise structural information about the components of deoxyribonucleic acid.

It thus appeared to us worth while to determine the crystal structure of a deoxyribotide, which is in effect one of the 'monomers' of deoxyribonucleic acid, so that direct evidence might be obtained of the mutual arrangement of the three fundamental groups: the phosphate, the sugar, and the base.

The calcium salt of thymidylic acid, which has the following structural formula, proved suitable for X-ray crystallographic analysis:



The salt was supplied to us by the California Foundation for Biochemical Research, and was recrystallized by careful evaporation of an aqueous solution. The crystal used for the X-ray work had approximate dimensions 1·5 mm. × 0·5 mm. × 0·2 mm.

X-ray photographs were taken with both Weissenberg and precession cameras and copper $K\alpha$ radiation. The dimensions of the monoclinic unit cell are: $a = 14{\cdot}40 \pm 0{\cdot}02$ A., $b = 6{\cdot}87 \pm 0{\cdot}01$ A., $c = 9{\cdot}81 \pm 0{\cdot}01$ A., and $\beta = 90° 58' \pm 3'$. The only systematic extinctions, $0k0$ with k odd, lead uniquely to the space-group $P2_1$ for this optically active molecule. The density of the crystal, measured by flotation in a mixture of 'Freon 113' and bromoform, lies between 1·58 and 1·61 gm./cm.^{3}; the density calculated on the assumption that the unit cell contains two molecules of calcium thymidylate, each accompanied by 6 molecules of water, is 1·60 gm./cm.^{3}.

Intensity photographs were taken by the equi-inclination Weissenberg method for the layers $k = 0$ to 5 and $l = 0$ to 8. The multiple film method was used and corrections were made in the usual way, although no absorption correction was applied. All diffraction maxima for which $s = \frac{2 \sin\theta}{\lambda}$ is less than 1·17 A.$^{-1}$ were measured; of the total of 1,788 reflexions, 214 were too weak to be observed.

The structure determination was first begun in Strasbourg with no other means of calculation than Beevers–Lipson strips. The Patterson projection on (010), together with certain general features of the diffraction photographs, gave the location of the calcium atom and the phosphate group, and permitted the approximate determination of the position and orientation of the sugar and the base. However, despite many attempts, uncertainties concerning individual atomic positions and especially the ignorance of the locations of the water molecules prevented our finding a trial structure sufficiently good to serve as the starting point for the usual convergence to a refined structure.

The structure was then resolved unambiguously from a sharpened three-dimensional Patterson function calculated on *Swac*[16]. By quantitative interpretation of this function we were able to determine the position of every atom of the molecule of calcium thymidylate and of several of the water molecules, although certain ambiguities remained with the latter at this stage. One round each of three-dimensional Fourier synthesis and of least squares have served to improve the atomic position and remove the ambiguities about the number and the positions of water molecules. Refinement of the structure is still in progress, but the atomic co-ordinates are now known with a precision which we estimate to be, on the average, better than 0·05 A. in x and z, and better than 0·1 A. in y. The approximate atomic co-ordinates are given in Table 1; O_9 to O_{14} are the six water molecules of the asymmetric unit.

Fig. 1 represents a projection of the electron density on the $x0z$ plane ; Fig. 2 is a projection of the structure on this same plane, while Fig. 3 is a projection of the structure on the plane $0yz$.

Even at this stage of refinement several conclusions can be drawn : (1) The arrangement of the phosphate group and the calcium atom relative to the two-fold screw axis is similar to that found by MacLennan and Beevers[17] for dicalcium phosphate. (2) All the atoms of thymine lie in a plane, essentially perpendicular to the b-axis. (3) The thymine molecules are packed together with their planes parallel to one another as in the model of deoxyribonucleic acid form B. Furthermore, the distance between the two bases ($b/2$ = 3·43 A.) is nearly identical with that found in deoxyribonucleic acid (3·40 A.). (4) The sugar is in the normal gauche form ; in addition, its plane is essentially perpendicular to the plane of the thymine residue, which confirms the result found by Furberg[12] for cytidine. (5) The structure is interlaced with a network of at least nine possible satisfactory hydrogen bonds, all but one of which involve at least one water molecule.

PHYSICAL SCIENCES

A New Value for the Earth's Flattening, derived from Measurements of Satellite Orbits

In a recent article[1] in *Nature*, we described how the Earth's gravitational field could be explored with the aid of satellites, and gave some results obtained from analysis of kinetheodolite observations of *Sputnik* 2 (1957β), the orbit of which was inclined to the equator at an angle near 65°. From observations of a single satellite, the coefficient J of the second harmonic in the Earth's gravitational potential could only be evaluated if the coefficient D of the fourth harmonic were given its conventional value of $10 \cdot 6 \times 10^{-6}$. On this assumption the value derived[1] for J was 1626×10^{-6}, corresponding to a value of 1/298·1 for the Earth's flattening (defined as the difference between equatorial and polar radii, divided by the equatorial radius), as compared with the previously accepted value[2] of 1/297·1. To obtain J and D independently, results from two satellites, of substantially different orbital inclinations, are required.

Accurate information is now available[3] for the rate of rotation of the orbital plane of the *Vanguard* 1 satellite (1958 β 2), the orbital inclination of which is near 34°. Combining the data from *Sputnik* 2 and *Vanguard* 1, we find $J = (1624{\cdot}6 \pm 0{\cdot}3) \times 10^{-6}$, $D = (6 \pm 1) \times 10^{-6}$. The corresponding value for the Earth's flattening is $1/(298{\cdot}20 \pm 0{\cdot}03)$. The standard deviations quoted are those arising from observational errors, and it is possible that somewhat larger errors may occur, because higher-order harmonics in the Earth's gravitational field have been ignored. The coefficient most likely to cause such errors is that of the sixth harmonic, J_6 in the notation of our previous article. We have now made a preliminary estimate of J_6 with the aid of the information so far available on *Explorer* 4 (1958ε), the inclination of which is near 50°, and find $J_6 = (0{\cdot}1 \pm 1{\cdot}5) \times 10^{-6}$: this causes no significant change in the values of J, D and flattening already quoted. Nor is there any significant change if the coefficient of the third harmonic J_3, derived recently[4] from perturbations to the orbit of *Vanguard* 1, is taken into account.

Heat-Flow Values from the South-Eastern Pacific

PRIOR to these new measurements, twenty-five heat-flow values from the Pacific Ocean Basin and eight from the Atlantic have been published[1]. The surprising fact brought out by these measurements is the approximate equality of average heat flow of the oceanic and continental areas, about 1×10^{-6} cal./cm.^{2} sec. This result was unexpected on the basis of values of radioactivity indicated for typical continental and oceanic crustal rocks existing near the Earth's surface. It has usually been assumed that most of the surface heat flow in continental regions must originate in the relatively thick and radioactive continental crust. Under the oceans, nearly all the average heat flow must come from the mantle beneath the relatively thin oceanic crust.

The new heat-flow values from the Pacific were obtained during October 1957–February 1958 on the Scripps Institution of Oceanography *Downwind* International Geophysical Year Expedition. The measurements are listed in Table 1, and the geographical distribution of stations, with generalized 4,000- and 5,000-m. bottom-depth contours of the area, is shown in Fig. 1. The topography was kindly supplied by Dr. Henry Menard of the Scripps Institution of Oceanography. The field technique was to measure the temperature gradient in the upper few metres of ocean floor sediment with apparatus first described by Revelle and Maxwell[2], and also the thermal conductivity of a cored sample of this sediment by a transient method[1]. The resulting heat-flow values are most probably accurate within 10 per cent, unless otherwise noted. The 'less than' or 'greater than' signs indicate the uncertainty of imperfectly functioning apparatus, usually due to an uncertainty of depth of penetration of the temperature gradient probe into the ocean floor. The thirty-six new measurements comprise a relatively more detailed study in a somewhat limited area, compared to the previous measurements.

When the new heat-flow values are considered together with the previous measurements in the Pacific, some interesting features can be seen. (1) The East Pacific Rise, a broad elevated region of the eastern Pacific sea floor, appears to be associated with a relatively narrow band of high heat flow for at least 6,000 km. along its length. This was indicated by three stations of the previous Pacific measurements[1], and is represented by stations 7, 8, 9, 10, 27, 29, 31 and 32 of the present study. (2) The axes of the trenches bordering the eastern Pacific Ocean appear to be associated with low heat flow. The previous Pacific measurements indicated this for the trench off Central America. Stations 18, 19, 20 and 21 respectively, of the present measurements, represent a series of heat-flow values down the eastern flank of a part of the South American trench, with the last two measurements in the deepest part. Station 17 is just west of the western flank of the same trench. (3) There seems to be fair evidence for areas with low heat flow roughly paralleling, and to each side of, the high heat-flow band of the East Pacific Rise. To the west, the low heat-flow area is represented by stations 1, 2, 5, 6, 35, 36 and one of the previous Pacific measurements. To the east of the Rise, the evidence for a low is not as good, being

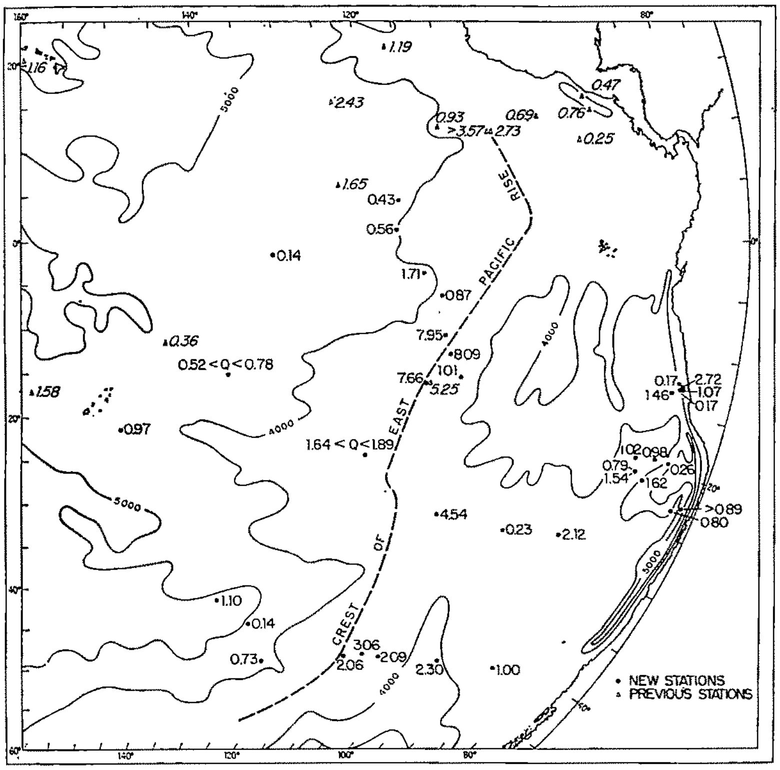

Fig. 1

represented only by station 26 and several of the previous Pacific measurements off the coast of Central America. The number of heat-flow measurements is not yet sufficient to establish how the trenches fit this general pattern; but the rough parallelism of the Rise and trenches may suggest a relationship.

An interesting result of these measurements is the extreme range of the heat-flow values, which extend from a low of $0 \cdot 14 \times 10^{-6}$ cal./cm.^{2} sec. to a high of $8 \cdot 09 \times 10^{-6}$ cal./cm.^{2} sec., a ratio of more than 1 : 50. Even though the area studied has large topographic features, where differences of heat flow might be expected, the large magnitude of the range of heat flow is somewhat surprising. It is believed that some of the variation in heat flow may be due to irregularities in bottom topography, or to an irregular surface of rocks of good thermal conductivity buried by a smooth sediment surface, as suggested previously[1]. Although it is difficult to evaluate the combined magnitude of these effects, it appears that they would not alter the observed heat flow at any station from the assumption of heat flow through uniform, horizontal layers by more than a factor of two, and would not be systematically distributed. The measurements have not been corrected for these disturbances, but irregular bottom topography may have had some effect on stations 6, 10, 11, 15, 16, and 30.

Undoubtedly, most of the variations observed in oceanic heat flow are due to differences in flow of heat from the mantle of the Earth. The pattern of heat flow in the eastern Pacific, if verified by further measurements, is suggestive of a large convective cell in the upper mantle of the Earth. The rising part of the convection cell, bringing hot material near the surface, may be represented by the East Pacific Rise, and the sinking parts by the possible low heat-flow areas on each side. Indeed, the lowest heat flows measured may be due entirely to the small amount of heat generated by radioactivity in the crust, with little or no heat coming from the mantle. The oceanic heat-flow values also show variations of relatively small horizontal extent not associated with topographic variations or with the large pattern, suggesting smaller-scale thermal anomalies in the mantle, perhaps also due to convection. A more closely spaced series of measurements in one of these areas is highly desirable.

Similar patterns may be expected for other areas of the Earth; high heat flow has been indicated also for the mid-Atlantic Ridge (Sir Edward Bullard, personal communication), a topographic feature of the Atlantic Basin similar to the East Pacific Rise. However, since convection could be driven by a deep distribution of radioactive heat sources under the ocean areas, it may be that similar patterns would not be observed in continental regions, where the radioactivity may be frozen uniformly in a relatively shallow crust. In fact, while the average heat flow seems to be about the same over continental and oceanic regions, the continental values show considerably less variation than the oceanic. However, this may result from a more limited distribution of continental heat-flow values; in fact, some areas of continents have been recently investigated which show unusually high heat flow[3,4]. Many problems have yet to be solved, and towards this end it is hoped that the results herein will be a stimulus for further measurements.

The measurements were made possible with the facilities of the Scripps Institution of Oceanography, and the interpretation of field observations was facilitated by a grant from the Institute of Geophysics, University of California. I wish to thank Prof. R. W. Raitt for encouraging the investigation and for many helpful discussions.

Improvement of the Fatigue Strength of Notched Specimens by artificially induced Residual Stresses

The question of whether or not residual stresses have any significant effect on fatigue strength has been the subject of much research for some time. However, in 1956 Puchner[1] showed that a large increase in the fatigue strength of specimens containing discontinuous longitudinal welds could be obtained by heating the specimen locally with an

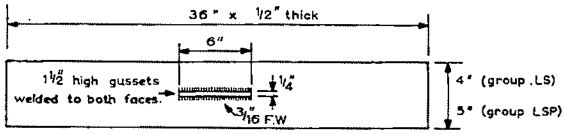

Fig. 1. Details of test specimens

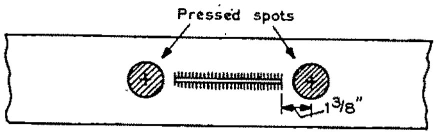
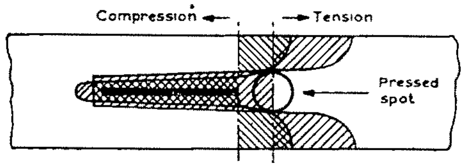


(a) Positions of compressed areas.



(b) Qualitative residual stress distribution due to pressing

Fig. 2

oxyacetylene torch, in such a way as to introduce residual compressive stresses at the site of the most dangerous notch from the point of view of fatigue failure (namely, at the ends of the welds). His results have been confirmed by recent work of the British Welding Research Association. In view of the potential practical importance of these results, it was decided to carry out an exploratory programme of tests to determine the effect of inducing residual stresses by mechanical means.

The specimens used in this investigation were fabricated from mild steel to British Standard 15, having a yield stress of 18·0 tons/in.^{2} and an ultimate tensile strength of 28·5 tons/in.^{2}. They consisted of flat strips with a single short longitudinal stiffening gusset fillet welded centrally on each face so that the two gussets were opposite each other (Fig. 1). Specimens in group *LS* formed a control series and were tested in the as-welded condition, but those in group *LSP* were compressed locally between $1\frac{3}{4}$-in. diameter dies in the position indicated in Fig. 2. The total load between the dies was 315,000 lb. which is equivalent to an average compressive stress of 58·5 tons/in.^{2}. Fig. 2 also shows, qualitatively, the residual stress distribution induced by the local compression, and it will be seen that the notches at the extremities of the welds were in areas of high longitudinal compressive stress.

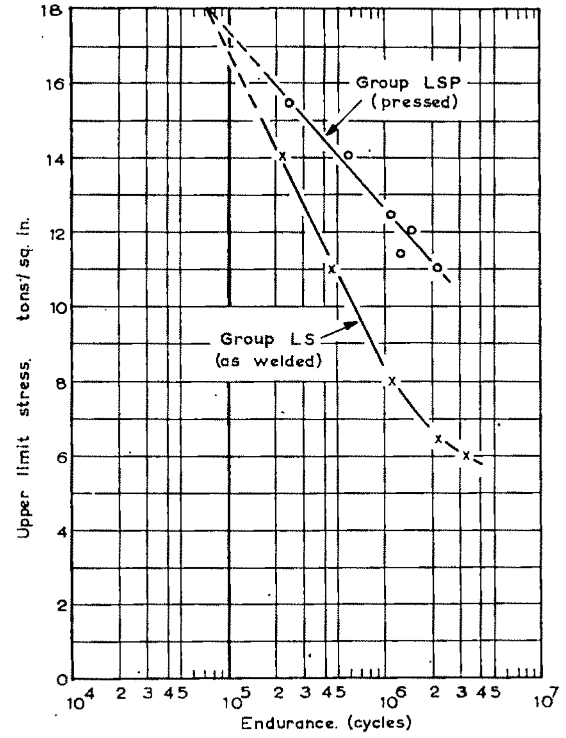


Fig. 3. Results of fatigue tests

All the specimens were tested under axial loading with a pulsating tension load cycle with a lower limit of zero, and the results obtained are shown in Fig. 3. It will be seen that for group *LS* the upper limit stress for an endurance of 2×10^6 cycles was 6·5 tons/in.^{2}, but that for group *LSP* this was increased to 11 tons/in.^{2}. An interesting point is that the two stress–endurance curves tend to converge at 18 tons/in.^{2}, the yield stress of the material. This was to be expected if the increase in fatigue strength were due to the induced residual stresses, since an applied tensile load of yield-point magnitude would result in 'mechanical stress relief' and eliminate their effects.

Thus it appears that specimens having clearly defined probable points for the initiation of fatigue failure can have their fatigue strength increased by compressing an area adjacent to the notch to such an extent that residual stresses are induced. The compressed area should be chosen so that the residual radial compressive stresses act in the same direction on the notch as the applied stresses. Further work is proceeding on this subject and this will be published elsewhere in due course.

Thermal Decomposition of Irradiated Solids

THE thermal decomposition, *in vacuo*, of potassium permanganate[1] and silver permanganate[2] crystals is markedly affected by pre-irradiation in *Bepo* or in a cobalt-60 hot-spot. The induction periods are shortened and the maximum velocities are increased. A mechanism has been suggested involving the growth of decomposition spikes and the accumulation of strain in the crystal over the induction period.

Similar work in progress in these laboratories has shown that cæsium and rubidium permanganates are affected in a like manner. However, pre-irradiation of silver oxide[3] in *Bepo* in a position near the outside (thermal neutron flux, 2×10^{11} n./cm.^{2}/sec.) for 48 hr., in a hollow uranium slug (fast neutron flux, 3×10^{11} n./cm.^{2}/sec.) for one week, and in a cobalt-60 hot-spot (dose-rate, $1\cdot6 \times 10^6$ rep hr.$^{-1}$) for 48 hr., produced no effect on the subsequent thermal decomposition; the pressure – time curves of irradiated and unirradiated specimens were almost superimposable.

Insufficient work has, as yet, been done in this field of research to draw any definite conclusions as to the class of solids which will be affected by pre-irradiation. However, certain characteristics are observable.

Garner and Moon[4] bombarded barium azide with the radiations from radium at room temperature with no effect on the subsequent thermal decomposition. Similarly, they found no effect on the decomposition of mercury fulminate.

Bowden and Singh[5] subjected lithium azide, lead azide, silver azide, cadmium azide, and silver acetylide to bombardment by electrons, thermal neutrons, fission products, and X-rays. The thermal decomposition of lithium azide was effected by thermal neutron bombardment (approx. dose, $2 \cdot 5 \times 10^{11}$ nvt) in a manner similar to that found for potassium permanganate, whereas cadmium and lead azides were only slightly affected. The published results for the last two substances, however, do not indicate the degree of reproducibility of results and the change could be due to experimental variation. No effect was found in the decomposition of silver azide. This substance melts on decomposition.

Simpson *et al.*[6] pre-irradiated ammonium dichromate with cobalt-60 γ-rays for four months. The intensity of the radiation was not given, but was stated to be low. The subsequent thermal decomposition showed an induction period only slightly less than normal, and the rate constant, k_1, for the acceleratory region changed from 0·0175 to 0·023, as calculated from the Prout–Tompkins equation[7], $\log_{10} p/(p_f - p) = k_1 t + c_1$, where p_f is the final pressure. The decompositions were stated to be reproducible to within only 20 per cent and it appears possible that this last difference might be attributed to other factors.

Flanagan[8] subjected lead styphnate monohydrate to a γ-ray dose of $1 \cdot 8 \times 10^6$ r. from cobalt-60 and found no effect on the thermal decomposition. Reactor irradiation, however, greatly affected the subsequent decomposition—the maximum rate of decomposition was increased three-fold by a neutron dose of $2 \cdot 2 \times 10^{18}$ nvt. The absence of any effect by γ-ray irradiation and the fact that significant changes were obtained only after heavy doses of neutrons ($> 10^{17}$ nvt) would suggest an irradiation effect different from that found with the permanganates where a dose of only 6×10^{13} nvt caused pronounced changes in the thermal decomposition.

The pressure–time plots of potassium, silver, cæsium, and rubidium permanganates and ammonium dichromate can be represented by the Prout–Tompkins equation or a modification of this equation[9]. The decomposition mechanisms associated with these equations involve the concept of branching chains. No analysis was given by Bowden and Singh of the pressure–time curves for lithium azide, but using the values obtained from a photographic enlargement of the published curve a good fit is obtained by the application of the Prout–Tompkins equation.

The power law, $p = k_2 t^n + c_2$, is obeyed for the decompositions of lead azide, lead styphnate monohydrate, mercury fulminate, silver oxide, and barium azide. Growth of nuclei in these cases is presumed to be normal and the effect of possible overlap between growing nuclei is not considered.

The theory proposed for the decomposition of irradiated potassium and silver permanganates postulates the displacement of potassium and silver ions into interstitial positions. The failure to observe any significant change in the length of the induction period (and perhaps k_1) in the decomposition of irradiated ammonium dichromate is due, possibly, to the presence of the more complex and not directly displaceable ammonium ion.

Thus, it would seem that the substances which are likely to be affected by pre-irradiation in the same way as the permanganates will be those containing a simple metal cation and decomposing according to a branching chain mechanism. Another requirement is that the decomposition spikes should create strain sufficient to crack or fracture the solid and thus create new, reactive surfaces.

The decomposition of lead oxalate[10] yields a typical sigmoid pressure–time curve which obeys the Prout–Tompkins equation. In view of the above observations an investigation of the effects of pre-irradiation on this substance is in progress.

Errors caused by Partial Drying of Hardened Portland Cement during Testing

It is known that incorrect estimates of the modulus of rupture and tensile strength may be obtained if Portland cement mortar or concrete specimens awaiting test are allowed to dry partially. Strength changes have also been observed when pozzolana-lime cement specimens begin to dry out[1], and, similarly, it has been demonstrated[2] that temporary reductions can develop in the modulus of rupture of road-making concretes, over a period of days, if the hardened mass is subjected to drying conditions.

The purpose of this communication is to emphasize the extreme magnitude of the change in strength which can be caused by partial drying of hydrated Portland cement, and to direct attention to the great rapidity with which this change can occur.

The results given here were obtained with small Portland cement paste prisms of ½-in. square cross-section, which had been cured for an initial 24 hr. in the moulds, and afterwards under water at 73° F. until tested at 56 days. A type 1 high alkali Portland cement was used at a water/cement ratio of 0·28 by weight. The results came from tests carried out at a temperature of approximately 75° F., in a laboratory which was not air-conditioned. The relative humidity was low at the time. The moduli of rupture given in Table 1 were obtained as follows.

Each row of results was obtained with specimens removed from the curing water at the same time. Since each test occupied 45–60 sec., the figures in column (*a*) are for specimens the surfaces of which had dried for not more than 1 min.; those in column (*f*) apply to specimens which had been exposed for 4½–6

Table 1. MODULUS OF RUPTURE (LB./IN.^{2}) OF PORTLAND CEMENT PASTE AT 56 DAYS

	a	*b*	*c*	*d*	*e*	*f*
1	1,040	910	1,000	980	1,040	—
2	1,380	1,110	1,140	900	—	—
3	1,750	970	1,050	910	1,090	990
4	1,960	1,930	1,790	2,200	2,300	—
5	1,670	2,310	2,150	1,840	1,860	1,950
6	1,730	2,020	2,090	1,750	1,770	—

min. It was observed that specimens 2*a* and 3*a*, which were tested with the very minimum of delay, apparently had higher strengths than the other prisms in rows 1–3. Since differential drying shrinkage was considered a possible cause of this behaviour, the remaining experiments (rows 4–6 inclusive) were completed with the prisms immersed in a water-bath at 75° F. during testing. A mean modulus of rupture of 1,960 lb./in.^{2} and coefficient of variation of 10 per cent was obtained with immersed specimens. This compares with a mean of 1,010 lb./in.^{2} and coefficient of variation of 8 per cent for tests performed after more than 1 min. of exposure in the air of the laboratory.

Equally large strength reductions have since been observed in additional experiments with 3 in. × 3 in. × 18 in. Portland cement paste beams which were allowed to dry for a short period in the air of the laboratory prior to testing.

CHEMISTRY

Structure of Glass

I HAVE shown[1,2] that there is a linear relation between the volume v associated with an oxygen ion in a glass and the composition of the glass. The relation for simple soda–silica glasses is:

$$v = 3\cdot8R + 14\cdot9 \qquad (1)$$

and for simple potash silica glasses:

$$v = 12R - 1\cdot2 \qquad (2)$$

where R is the number of oxygen ions per network-forming atom. v is modified by the introduction of a third oxide into soda or potash glass. Introduction of a network-forming oxide should be allowed for in the calculation of R and then v can be obtained from equations (1) or (2) with a slight modification of the additive constant (15·1 for glasses containing alumina and 14·6 for those containing beryllia). Boron trioxide causes a further correction and then:

$$v = 3\cdot8R - 2\text{Na}^* + 14\cdot65 \qquad (3)$$

Chemical symbols with an asterisk denote the number of gram-ions in 100 gm. of glass.

Introduction of certain cations in soda or potash glass contracts or expands the network proportionally to the concentration, each oxide having its own factor, which is constant over a wide range of compositions. The factors are different for soda and potash glasses, but they remain constant when several substances are introduced, that is, they do not influence each other. The factors in Table 1 have been determined.

Table 1

Ion	Radius (A.)	Factor for soda glass	Factor for potash glass
Li^+	0·70	− 2·4	−12
Na^+	0·98	0	− 2
K^+	1·38	+ 4	0
Rb^+	1·49	—	+ 4
Mg^{2+}	0·78	− 5	−13
Ca^{2+}	1·06	− 5	−12
Sr^{2+}	1·22	− 3	—
Ba^{2+}	1·43	− 0·5	− 9
Zn^{2+}	0·83	− 2	—
Pb^{2+}	1·32	+ 0·5	− 9
Fe^{2+}	0·83	− 4	—
Fe^{3+}	0·63	− 6·5	—
Bi^{3+}	1·24	− 9	—
Ti^{4+}	0·65	−11	—
Zr^{4+}	0·77	−10	—
Ta^{5+}	0·68	—	−36

The complete equation for glasses with a soda basis is therefore:

$$v = 3\cdot8R - 2\cdot4\text{Li}^* + 4\text{K}^* - 5\text{Mg}^* - 5\text{Ca}^* - 3\text{Sr}^* - 0\cdot5\text{Ba}^* - 2\text{Zn}^* + 0\cdot5\text{Pb}^* - 4\text{Fe}^{\text{II}*} - 6\cdot5\text{Fe}^{\text{III}*} - 9\text{Bi}^* - 11\text{Ti}^* - 10\text{Zr}^* + 14\cdot9 \qquad (4)$$

and for glasses with a potash basis:

$$v = 12R - 12\text{Li}^* - 2\text{Na}^* + 4\text{Rb}^* - 13\text{Mg}^* - 12\text{Ca}^* - 9\text{Ba}^* - 9\text{Pb}^* - 1\cdot2 \qquad (5)$$

It can be seen that the smaller the radius and the larger the valency of the ion, the greater its contracting effect; an expanding effect is rarer and is larger for an ion with smaller valency. The contraction of potash glasses, which have considerably larger v values, is much larger than that of soda glasses. The effect of ions which do not have a noble gas structure is smaller.

Calculations have been made for more than 500 glasses, including a few with 8 and one with 9 components. The largest discrepancy is 1·5 per cent; in most cases it is a few tenths of 1 per cent.

From the results in Table 1 we can deduce that:

(1) Li+ is not a network-forming ion, but a modifier; otherwise the calculations do not give a reasonable value for v (lithium oxide content 0–15 per cent).

(2) Zn^{2+}, Ti^{4+} and Zr^{4+} are also modifiers (titanium dioxide content 2·04–9·89 per cent, zinc oxide content 1·29–11·39 per cent, zirconium dioxide content 2·67–20·96 per cent).

(3) Be^{2+} is a network-former (beryllium oxide content 4·78–30·95 per cent).

(4) Al^{3+} is also a network-former (aluminium oxide content 0–25·3 per cent).

No ion has been found to have an intermediate behaviour.

These conclusions are confirmed by a calculation of the thermal expansion coefficients (α) on a new basis. It is well known that α can be calculated roughly by adding together the oxide percentages multiplied by appropriate factors. A number of different sets of factors exist[3,4], but none of them gives satisfactory results if used for widely differing glasses; the differences between measured and calculated values sometimes amount to more than 10 per cent and they are quite useless for borosilicate glasses. A new equation is suggested for the coefficient of linear expansion, which contains an additive constant besides the oxide percentages multiplied by new factors; the additive constant varies somewhat with temperature (this has scarcely been considered by former investigators). The new equation, between 0° and 100° C., is:

$$10^8\alpha = 100(Li_2O) + 35(Na_2O) + 30(K_2O) - 8(MgO) + 10(CaO) + 8(BaO) + 6(PbO) + 4(Fe_2O_3) - 6(ZnO) - 6(ZrO_2) + A \quad (6)$$

where the additive constant A is 200 for common glasses (containing less than 5 per cent of lead, barium or zinc oxides), 280 for glasses with more than 5 per cent lead oxide, 220 for glasses with more than 5 per cent barium oxide and 250 for glasses with more than 5 per cent zinc oxide, between 0° and 100° C. The thermal expansion coefficients of more than 220 glasses have been calculated in this way; the average error in the different series varies from 0·7 per cent to 2·2 per cent for boron-free glasses, 2·5 per cent for borosilicate glasses and 3·5 per cent for glasses containing titanium dioxide.

A very striking fact is that the thermal expansion is largely due to the alkali ions; the effect of alkaline earth ions is small, while that of Fe^{3+}, Zn^{2+} and Zr^{4+} is even smaller. All other ions have a negligible influence on the thermal expansion; the network-forming ions are without any effect. The oxides of beryllium and aluminium behave in this respect quite like silica, boron trioxide and phosphorus pentoxide.

The existence of a continuous non-periodic tetrahedral network seems to be indicated by these results, although the rigorous conditions proposed by Zachariasen[5] cannot be maintained in some cases.

Estimation of Strontium in Animal Bone using X-ray Fluorescence Analysis

PREVIOUS work on strontium estimation in biological material has involved the use of optical emission spectroscopy[1] and flame spectrophotometry[2], both of which suffer from the disadvantage that the sample is destroyed during the analysis. This can be a significant factor when, in the interest of precision, the analysis must be repeated several times on each sample, when the quantity of material from any particular region of a bone is small, or when the sample is to be used for radiometric estimation of strontium-90.

X-ray fluorescence spectroscopy offers a fairly straightforward method for the estimation of strontium in animal bone, because the spectra of the major constituents, calcium and phosphorus, do not interfere with the strontium $K\alpha$ spectral line used in this analysis; and any of the heavier elements which may interfere are present in such small concentration that their effects can be ignored.

As a consequence of these two factors, no internal comparison element is necessary, and a direct measurement of intensity on the strontium $K\alpha$ line is sufficient to give the concentration of strontium.

Discounting instrumental error, the accuracy of the method will depend upon obtaining the maximum intensity of the fluorescence radiation, and upon the absolute reproducibility of the method of specimen preparation. This latter factor ensures that variations in intensity of the strontium $K\alpha$ radiation are due to variations in concentration and not to differences in the specimen surface exposed to the incident beam.

To obtain these two requirements the following method of specimen preparation was evolved.

A 2-gram sample of bone ash was ground to − 200 mesh, 2 drops of flexible collodion added as a binder, and the whole ground in acetone to achieve a uniform distribution. The dried powder was then compressed in a suitably shaped die, using a sheet of polished high tensile steel for the working face of the specimen, to a pressure of eight tons. The resultant disk has sufficient strength to be self-supporting, and offers an exactly identical surface to the X-ray beam in every sample, giving the desired specimen reproducibility.

The high compression also ensures that a maximum quantity of material is available at the immediate surface for the generation of secondary radiation. Because the sample is self-supporting its surface can be placed directly in the primary beam; no 'Mylar' film or other supporting medium is necessary. As a result the maximum intensity can be obtained.

The standards used in the construction of the working curve were made from human bone ash to which increments of strontium were added in the form of an aqueous solution of strontium nitrate, containing 0·2415 gm. in 100 ml. of water, giving a solution containing 1,000 p.p.m. To 19·9517 gm. of human bone ground to − 200 mesh was added 20 ml. of this solution. To achieve a uniform distribution of strontium, 100 ml. of acetone was added, and the whole mixed thoroughly until dry. This gave 20 gm. of bone ash containing 1,000 p.p.m. of strontium in addition to its normal strontium content.

This bulk material was diluted with bone ash to give 2-gm. standards of 100–800 p.p.m. in increments of 100 p.p.m., which were pressed into disks by the previously described method.

The intensities of the strontium $K\alpha$ line and background were measured for each sample. The intensity of the line was also measured in the same manner on a bone sample to which no strontium had been added. The intensity for the added strontium in each standard was then obtained by subtracting the background intensities and the strontium $K\alpha$ intensity of the bone standard.

The instrumentation used was: Philips X-ray spectrograph *PW*1520; quartz analysing crystal; Geiger counter operating at 1,700 V.; X-ray path evacuated; tungsten target, 50 kV. 20 m.amp.

The method of 'constant accuracy' counting was used, and 32,000 counts were taken on both the strontium line and the background on each sample. At the intensities under consideration the dead-time losses for the counter are so small that they can be ignored.

From the data obtained a curve was plotted by the least-squares method, and the standard deviation for the individual readings calculated from the method described by Youden[3]. The curve is shown in Fig. 1. The standard deviation is 8 p.p.m.; for 95 per cent confidence limits the standard deviation will be 16 p.p.m.

For the actual analyses the samples were run in triplicate, so that for 95 per cent confidence limits the standard deviation will be ± 10 p.p.m.

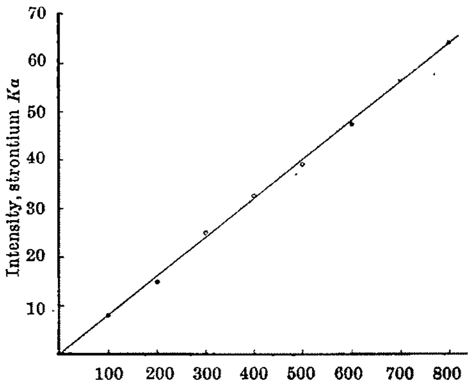

Fig. 1

Some results for bones of two adults labelled Adult 1 and Adult 2 are given in Table 1.

Micro Determination of Calcium

Hildebrand and Reilly[1] have recently described a complexometric titration method for the determination of calcium: the indicator used, 'Calcon', is superior to 'Solochrome' black in that calcium can be determined independently of magnesium, and, unlike the murexide method, a sharp end-point is obtained. All three methods employ ethylenediamine tetraacetic acid. The purpose of the present communication is to direct attention to the facts: (*a*) that the allied compound 1-(1-hydroxy-2-naphthylazo)-5-nitro-2-naphthol-4 sulphonic acid sodium salt (Eastman-Kodak) appears to be just as suitable as an indicator as 'Calcon' but is considerably cheaper; (*b*) that the method can also be used on an ultra-micro scale. Concentrations of the order of 10^{-2} µgm. calcium have been determined in volumes of about 40λ of solution with an accuracy of 1 per cent (1λ = 0·001 ml.).

Essentially, the method is similar to the original[1], and relatively the same quantity of buffer (diethylamine) is employed; in fact, it was found that the quantities of both buffer and indicator were critical. For 40λ of solution 1·75 ± 0·25λ of diethylamine maintained the required *p*H of 12–13, and accurate and repeatable results were obtained with 5 ± 0·5λ of indicator: these volumes were delivered with microburettes.

The cap of a 1-cm. 'attached-cap' polythene tube was found superior to a waxed slide for the titration: not only is the surface suitable, but also, lighted from below, the drop of solution is very suitably illuminated for observation of the end-point. The solution was brought into contact with the glass needle of the burette, a 100-λ pipette graduated in 1λ units (Glen-Creston, Ltd.), and titration continued until all trace of pink had disappeared and the solution turned pale blue[1]: at this stage the addition of 0·5λ of 0·0002 *N* ethylenediamine tetraacetic acid produced a marked change of colour. Stirring was carried out by a fine jet of air.

The stock solution of 0·02 *N* ethylenediamine tetraacetic acid keeps for many months without deterioration: however, the 0·0002 *N* solution prepared from it for titration was less stable and was therefore freshly prepared each week.

Determinations on twenty-one 40-λ samples containing $7{\cdot}96 \times 10^{-3}$ µgm. calcium diluted from a gravimetrically standardized solution gave a mean value of $7{\cdot}90 \pm 0{\cdot}80 \times 10^{-3}$; the difference is therefore less than 1 per cent from the expected value, and is far from statistical significance ($P > 0{\cdot}7$). Six or fewer determinations with a series of solutions of greater calcium concentration gave mean values which, as shown in Fig. 1, were also very close to those expected. Mean values were usually within 2 per cent, and never more than 4 per cent from the known values.

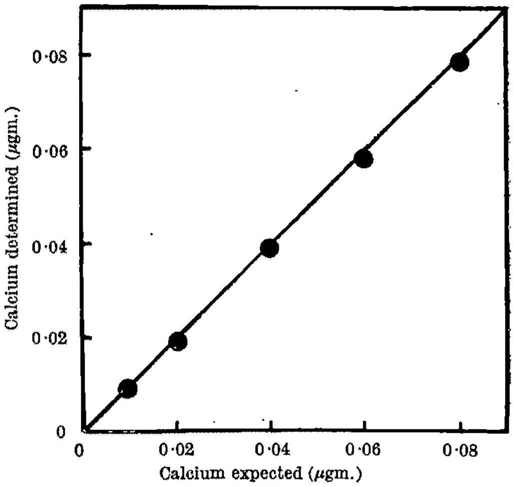

Fig. 1. Continuous line represents expected values. Closed circles are mean values of, from left to right, 21, 3, 3, 5 and 6 determinations of 40-λ samples

BIOCHEMISTRY

Production of Amide Groups and Ammonia in the Radiolysis of Aqueous Solutions of Protein

RECENT studies in this Laboratory have indicated[1,2] that a principal reaction in the radiolysis of aqueous solutions of protein under certain conditions involves cleavage of the peptide chain to form the carbonyl and amide functions as represented by the reaction :

$$\text{—CO—NH—CH}(R)\text{—} + O_2 + H_2O \rightsquigarrow \text{—CONH}_2 + R\text{CO—} + H_2O_2 \quad (1)$$

Evidence for this type of radiation-induced oxidation has been derived largely from studies of carbonyl production in oxygenated solutions of pepsin and gelatin. The carbonyl function is found to be associated with high molecular weight (non-dialysable) products which on conventional acid hydrolysis yield a series of α-keto acids. A correlation of these results in terms of a detailed mechanism for reaction (1) has been given elsewhere[2].

Substantiating evidence for the reaction as written has now been obtained from studies of the amide content of reaction products formed by γ-ray-induced oxidation of aqueous gelatin. Commercially available lime-process gelatin was found to be particularly suitable for this study since most of the amide groups of the glutamine and asparagine residues of the parent collagen are removed through hydrolysis during the manufacturing process[3]. Unmodified proteins, in general, contain amide groups in sufficient number to mask reaction (1) at the lower radiation dosages necessarily invoked in studies of initial reaction products.

Analyses were made for 'free' ammonia and for amide groups, both before and after irradiation. The stock solutions (3·5 per cent gelatin, purified calfskin, Eastman Lot 60-9680) had been previously dialysed to reduce the content of ammonia to a minimum value. Analytical procedures were, in brief, as follows : an appropriate aliquot of the solution was made alkaline to phenolphthalein and distilled at room temperature *in vacuo* into a receiver which contained 1 ml. of 0·1 *N* sulphuric acid at the temperature of liquid nitrogen. The distillate was isolated, thawed, and then assayed for ammonia by means of the Nessler reaction. A second aliquot of each solution was made 1 *N* in hydrochloric acid and heated for 1 hr. at 95° C. to liberate ammonia from amide linkages[4]. Subsequent treatment was then as described for ammonia. A series of control runs showed that the liberation of amide-ammonia was essentially quantitative under the mild hydrolysis conditions employed. Prolonged hydrolysis leads to the gradual breakdown of various labile amino-acids with the formation of what in this study would be 'artefact' ammonia[5,6]. An increase of 25 per cent in the number of amide groups in an irradiated solution as compared to the corresponding control solution could easily be observed with the method outlined above. Results shown in Table 1 were obtained on solutions that had been irradiated until the amide and ammonia content had reached values that were at least three times those of the control.

A 2,000-c. cobalt-60 γ-ray source was used in the irradiations. Solutions (10 ml.) were exposed under oxygen (5 ml.) at one atmosphere in sealed 'Pyrex' tubes. Contents were shaken at intervals to prevent depletion of oxygen in the solutions. The dose-rate was $2 \cdot 5 \times 10^{18}$ eV./ml./min.

Table 1. PRODUCTION OF AMIDE GROUPS AND AMMONIA IN THE γ-RAY RADIOLYSIS OF AQUEOUS GELATIN SOLUTIONS

	Yield (*G*)*	
	Series 1	Series 2
Amide groups	1·0 ± 0·1	0·9 ± 0·1
Ammonia	0·25 ± 0·05	0·30 ± 0·05

* Yield per 100 eV. absorbed energy

The results in Table 1 indicate that the formation of amide groups ($G \simeq 1$) corresponds to a principal reaction in the radiolysis of aqueous solutions of gelatin. Further, the *G* value for this product-group is very close to that obtained for total carbonyl formation under equivalent irradiation conditions[2]. The simplest explanation for these results would seem to involve the postulated reaction (1). Ammonia formation ($G \simeq 0 \cdot 3$) may be attributed to a radiation-induced oxidation of terminal and/or side-chain amino groups[7].

This work was performed under the auspices of the United States Atomic Energy Commission.

Anion Inhibition of α-Glycerophosphate Dehydrogenase

RABBIT-muscle α-glycerophosphate dehydrogenase, which catalyses the reaction :

$$\text{dihydroxyacetone phosphate} + \text{DPNH} + \text{H}^+ \rightleftarrows \alpha\text{-glycerophosphate} + \text{DPN}$$

was first crystallized by Baranowski[1]. More recently, Beisenherz *et al.*[2] and Young and Pace[3] have reported work in which this enzyme was studied with respect to a number of physical and chemical properties. In all cases where the above reaction was studied by measuring the reduction of dihydroxyacetone phosphate, this substrate had been prepared enzymatically[4]. In connexion with work on the metabolism of acetol phosphate (monohydroxyacetone phosphate)[5], dihydroxyacetone phosphate was prepared by the procedure described by Ballou and Fischer[6] and it was used in the experiments reported here. It was observed that dialysis of solutions of α-glycerophosphate dehydrogenase—which contained ammonium sulphate during preparation by the published procedure[2]—resulted in an appreciable loss of activity in some fractions (details of these experiments will be published elsewhere). Activities were determined by the spectrophotometric method of Beisenherz *et al.*[2]. When ammonium sulphate was added back

Table 1. Effect of Salts on the Activity of Dialysed α-Glycerophosphate Dehydrogenase

Salt added*	Percentage inhibition
None	0
Ammonium sulphate	65
Potassium sulphate	65
Sodium sulphate	67
Ammonium chloride	60
Potassium chloride	54
Sodium chloride	45
Ammonium formate	21
Ammonium formate†	40
Sodium formate	12
Sodium formate†	44
Ammonium sulphite	88
Sodium sulphite	85

For the measurement of the enzymatic activity, △ optical density (340 mμ) per 40 sec., the reaction mixture contained, in 3·0 ml. of total volume, dihydroxyacetone phosphate (1×10^{-4} *M*), reduced diphosphopyridine nucleotide (about $1·5 \times 10^{-4}$ *M*), *tris*(hydroxymethyl) aminomethane buffer, *p*H 7·7 (4×10^{-2} *M*), α-glycerophosphate dehydrogenase (53 μgm., specific activity, 180), which was dialysed for 24 hr., and the salts listed below, to give the ionic strength indicated. In the control cuvette, reduced diphosphopyridine nucleotide was replaced by an equal volume of distilled water

* The ionic strength due to the addition of the salt was 0·19.

† Ionic strength was 0·57.

to the previously dialysed enzyme, a strong diminution of activity was noted as compared to activity of dialysed enzyme to which no ammonium sulphate was added. It was established, by comparing the effect of the corresponding sodium and potassium salts on the enzymatic activity, that this inhibitory effect was due to the anionic portion of the ammonium sulphate molecule. In addition, the ammonium, sodium and potassium salts of hydrochloric acid and the ammonium and sodium salts of formic and sulphurous acids were tested for an inhibitory effect.

Table 1 shows that, at an ionic strength of 0·19, *p*H 7·7, 24° C., the percentage inhibition of the enzymatic activity was a function of the particular anion tested. It can be seen also that an increase in ionic strength resulted in an enhancement of the observed inhibition in the case of formate. The influence of some sodium salts of different anions on the activity of α-glycerophosphate dehydrgoenase was then studied, and it was noted that, with the exception of glycine and ethylenediamine tetraacetate, all the anions tested exhibited inhibitory properties (Table 2). The ability of sulphite to inhibit α-glycerophosphate dehydrogenase was recently reported by Pfleiderer *et al.*[7], who observed that 20–50 μgm. of sulphite caused 25 per cent inhibition. The present results, in which 30 μgm. of sulphite ($3·8 \times 10^{-4}$ *M*, Table 2) were shown to inhibit the dialysed enzyme by 17 per cent, are in good agreement with the findings of Pfleiderer *et al.*[7], who used undialysed enzyme preparations. It is of interest to note that the failure of glycine and ethylenediamine tetraacetate to inhibit α-glycerophosphate dehydrogenase, under the experimental conditions employed, bears resemblance to the results obtained by Theorell *et al.*[8] with liver alcohol dehydrogenase.

Table 2. Effect of Anions on the Activity of Dialysed α-Glycerophosphate Dehydrogenase

Anion	Final concentration of added salt (*M*)	Percentage inhibition
None	—	0
Acetate	$1·9 \times 10^{-1}$	38
Bicarbonate	$1·9 \times 10^{-1}$	65
Glycine	$1·9 \times 10^{-1}$	0
Bromide	$2·3 \times 10^{-1}$	55
Nitrate	$2·3 \times 10^{-1}$	59
Azide	$5·0 \times 10^{-6}$	14
Azide	$5·0 \times 10^{-4}$	18
Azide	$5·0 \times 10^{-2}$	22
Sulphite	$3·8 \times 10^{-4}$	17
Sulphite	$3·8 \times 10^{-3}$	33
Sulphite	$3·8 \times 10^{-2}$	78
Sulphite	$6·3 \times 10^{-2}$	85
Sulphate	$6·3 \times 10^{-1}$	95
Phosphate	$4·7 \times 10^{-2}$	52
Ethylenediamine tetraacetate	$1·1 \times 10^{-2}$	0

The assay system, as described in Table 1, was used. The sodium salt solutions were adjusted to *p*H 7·5–7·9 prior to their addition to the cuvette

The observed high sensitivity of the dialysed α-glycerophosphate dehydrogenase to sulphate, an anion to which the enzyme is entirely stable prior to dialysis, may be tentatively explained by assuming that the prolonged dialysis causes the rupture of the bond between the nucleotide and the enzyme to which the nucleotide is known to be intimately bound[1,2]. This results in the exposure of active sites on the enzyme surface with a high but rather non-specific sensitivity to anions.

This work was supported by the Division of Grants and Fellowships, National Institutes of Health, U.S. Public Health Grant No. *H*-1525. The results were taken from a thesis submitted by Otto Z. Sellinger to the Graduate School of Tulane University in partial fulfilment of the requirements for the degree of doctor of philosophy.

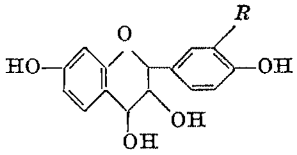
Flavan-3.4-diols and Leuco-anthocyanidins of *Guibourtia* spp.

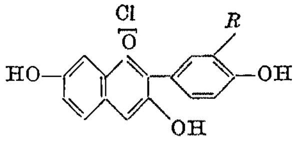
Probably the most interesting of the large number of heartwood specimens previously examined[1] on two-way paper chromatograms by the toluene-*p*-sulphonic acid reagent[1,2] are the extractives of some of the species of the genus *Guibourtia*, previously known as *Copaifera*. Those extractives of *Guibourtia coleosperma*, *G. tessmannii* and *G. demeusei* which are soluble in methanol, for example, redden rapidly on exposure to direct sunlight and furnish high yields of anthocyanidins when treated with 3 *N* hydrochloric acid/propan-2-ol (1 : 5) under pressure[3] (about 8 per cent yield) or under anhydrous conditions with *N*/40 hydrochloric acid[4] (about 13 per cent yield). These extractives may be fractionated into a high proportion of tannins insoluble in water and with an average molecular weight of about 2,200, and a low proportion of polyphenols and carbohydrates soluble in water. Examination of the latter fraction with the toluene-*p*-sulphonic acid spraying reagent on two-way paper chromatograms shows the probable presence of flavan-3.4-diols with R_F values corresponding to 0·45–0·55 in 2 per cent acetic acid (second irrigant), but with differing R_F values in the partitioning mixture used (butan-2-ol saturated with water : first irrigant)[5].

Two such compounds have been isolated in low yield, and were examined more closely as they appear to be directly related to the constitution of the highly condensed tannins present. Component I (R_F = 0·54 and 0·59 respectively) gives the same colour reactions and runs to the same position on two-way chromatograms as (+)-7.3′.4′-trihydroxyflavan-3.4-diol (mollisacacidin[6] and gleditsin[7]). Heating with alcoholic hydrochloric acid[3] affords a pink anthocyanidin, fisetinidin chloride (compound III, R = OH), and the compound undoubtedly is a 'leuco-fisetinidin' of structure I (R = OH).

Component II (R_F = 0·53 and 0·78 respectively) shows very weak reducing properties towards ammoniacal silver nitrate in the cold and its chromatographic behaviour in the partitioning mixture (R_F = 0·78) suggests that it has one hydroxyl group less than the accompanying 'leuco-fisetinidin' (R_F = 0·59)[8]. Furthermore, the weak reducing properties of II compared with I suggest that the new compound contains no vicinal hydroxyl groups on the *B* ring. Most significant, however, is its conversion in about 20 per cent yield into the yellow anthocyanidin, 3.7.4′-trihydroxyflavylium chloride[9] (compound IV, R = H) ($\lambda_{max.}$ = 490 mμ and R_F 0·60 in 3 *N* hydrochloric acid/90 per cent formic acid (1 : 1)). This and other evidence suggest that the compound has the structure 7.4′-dihydroxyflavan-3.4-diol (component II, R = H). This substance therefore appears to be the third member of the series of flavan-3.4-diols containing resorcinol, for example, leuco-robinetinidin[10], leuco-fisetinidin[6,11] and 7.4′-dihydroxyflavan-3.4-diol. The trivial names guibourtacacidin and guibourtinidin are proposed for the new leuco-anthocyanidin (component II, R = H) and for the anthocyanidin (compound IV, R = H)[9] generated from II respectively.



I, R = OH
II, R = H



III, R = OH
IV, R = H

Significance is attached to the observation that where these flavan-3.4-diols are present in *Guibourtia* species, the high molecular weight tannins which accompany them furnish high yields of both fisetinidin and guibourtinidin chlorides.

Further work on these compounds is in progress and will be published elsewhere.

ANIMAL PHYSIOLOGY

Chlorothiazid in Diabetes Insipidus

Laragh and his co-workers[1] have demonstrated that chlorothiazid administered to normal subjects in the midst of a sustained water diuresis provokes a flow of urine of substantially higher concentration for a given rate of total osmolar output than urine formed by water-loaded subjects to whom meralluride is given. On the basis of this finding, they suggested that the site of action of chlorothiazid was in the distal portion of the nephron. Here, they postulated that the drug inhibited the production of 'free water' which normally results from selective re-absorption of sodium and accompanying anions. A drug acting to interfere with free-water formation would be of therapeutic value to the patient with diabetes insipidus, particularly the nephrogenic sort, if attendant losses of electrolyte in the urine were not unduly large, or, indeed, should they fail to occur.

Much more severe and sustained diabetes insipidus can be induced in the rat by electrolytic damage to the hypothalamus[2] than by the more usual technique of surgical removal of the posterior lobe of the pituitary gland. The technique consists of complete, or almost complete, destruction of the connexions in the anterior hypothalamus between the supra-optic nucleus and the pituitary stalk. The tracts concerned are difficult to identify in the rat[3] but are probably diffuse. The best combination of high survival-rate with severe diabetes insipidus is obtained by introducing stereotaxically two contiguous pairs of lesions at separate operations, allowing a recovery interval of 7–10 days. An initial pair of bilateral lesions gives rise to a mild diabetes insipidus characterized by water requirement ranging from just above normal (about 20 ml./250 gm. rat) to as much as 100 ml. a day when the adult animals consume quantitatively 20 gm. of diet 41 described by Bruce and Parkes[4]. The more severely affected animals are selected and respond to a second, similar operation by a marked increase in polyuria. On the same, 20 gm. diet allotment intakes of water following this procedure may exceed 400 ml. a day or almost twice the body-weight of the animal. The doubly operated animals fail to reduce the rate of flow of their urine in response to nicotine, hypertonic saline injection or 2-phenyl, 3-hydroxycinchoninic acid[5]. Sustained water-loading does not provoke flows of urine significantly in excess of those seen during *ad libitum* drinking, and water restriction results in marked dehydration, food refusal and loss of body-weight.

Chlorothiazid has been administered to animals with this form of severe diabetes insipidus by admixture with the daily food ration. They respond within 24 hr. by reduction of intake of water by 50 per cent or more as indicated in Fig. 1. Urine osmolality rises from hypotonic levels to approach and, in some instances, to exceed by a small margin the tonicity of plasma. Urine *p*H is essentially unchanged, and the animals show no tendency to lose weight. The effect of the drug is sustained over long periods of time but disappears promptly on cessation of treatment. No influence on water turn-over is seen in similarly treated control animals. Nevertheless, in animals with submaximal diabetes insipidus, however mild, chlorothiazid causes the same proportionate reduction of water turn-over as it does in the more severe cases. Doses of 80 mgm./kgm. body-weight give a detectable effect ; maximal response is seen at dose-levels of 300 mgm. a day and twice this dose has been reported to be well tolerated in normal rats for as long as six months[6].

The effect described for the rat is not species specific but has been reproduced in two human subjects, one with diabetes insipidus due to lack of vasopressin, the other with the nephrogenic type which is insensitive to the hormone. Within an hour of initial chlorothiazid administration there may occur an increase in urinary sodium, chloride and potassium excretion rates as well as a rise in urine osmolality. Urinary *p*H is not appreciably influenced. The solute diuresis is of brief duration ; but the elevation in osmolality persists and within 6 hr. volume of urine begins to fall. The response of one patient in terms of the changes in urine volume and osmolality calculated on a 24-hr. basis is shown in Fig. 2. It will be noted also that though the dose requirement of the rat appears large, responses in the human are obtained at the same dose-levels as are employed when the drug is used as a diuretic. Clinical trials are being continued and will be reported elsewhere.

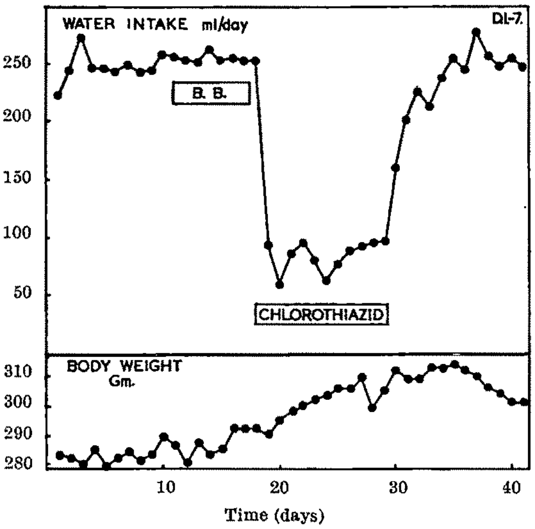

Fig. 1. Influence of chlorothiazid, 300 mgm./kgm. a day, on spontaneous water intake and body-weight of a rat with diabetes insipidus. The failure of di-*n*-butylamido-*p*-carboxybenzenesulphonate (50 mgm./kgm. a day) to influence either of these variables is shown by the block labelled *B.B.*

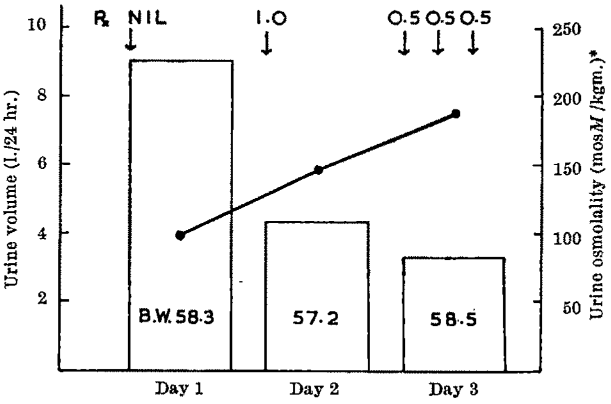

Fig. 2. Influence on urine volume (columns) and osmolality (interconnected points) of chlorothiazid in a woman with vasopressin insufficiency diabetes insipidus of three years duration. Day 1 represents a control 24-hr. period during which no treatment was given. A single 1-gm. dose was given at the start of day 2. On day 3, doses of 0·5 gm. were administered at 8-hourly intervals. Water to drink was allowed *ad lib.* and the diet was essentially constant throughout. Body-weights are given by the figures in the lower portions of the columns

Mrs. O. S. (46 yr.)

* This figure denotes total effective osmolal concentration of the urine in milliosmoles per kilogram of water found by determination of the urine's freezing point depression and division of the latter figure in deg. C. by the constant, 1·86.

The mechanism of action of the drug remains obscure. Treatment of the diabetic animals with heavy doses (100 mgm./kgm. a day) of the much more potent carbonic anhydrase inhibitor, acetazoleamide, results in no appreciable antidiuresis. Moreover, far more active inhibitors of tubular transport of *p*-amino-hippurate, phenol red and penicillin such as probenecid and its di-butyl analogue, which have been reported by Bachman[7] and Polster[8] to lessen the water turn-over in human diabetes insipidus, are similarly ineffective. Although the mechanism proposed by Laragh[1] may be invoked to explain the initial effect, its acceptance requires that one must postulate in addition a prompt, secondary adjustment leading to re-absorption of electrolytes at some site other than the point of free-water formation, since long-term therapy is well tolerated by the animals. Studies designed to clarify the mechanism by which the drug acts are in progress.

Changes in the Group *A* Antigen in a Case of Leukæmia

Van Loghem and his colleagues[1] and Stratton *et al.*[2] have each reported a case in which a patient's group *A* antigen became weakened during the course of an illness. Salmon *et al.*[3] observed a similar case in which the red cells showed a 'double-cell population'. We have had the opportunity to observe a further example of weakening of the A antigen, with double-cell population, and, in addition, a partial reversion towards normal during a temporary clinical remission.

A male patient aged nineteen years was admitted to hospital because of acute monoblastic leukæmia. In routine blood grouping tests for a transfusion his red cells were very weakly agglutinated by the anti-A grouping serum. Anti-B agglutinins were present in his serum in normal titre. A differential agglutination test showed that approximately 2 per cent of the cells were agglutinated by potent anti-A sera; but the remainder, although inagglutinable, absorbed anti-A to the same extent as A_2 cells. This anti-A could readily be eluted by the heat-method. 3 days later, the red cells in a fresh sample were no longer agglutinable, even by selected group O 'immune' anti-A sera, but continued to absorb anti-A. At this time, the total white cell count was 118,000 per cu. mm., of which approximately 90,000 were 'blast' cells.

After treatment for 8 weeks with 6-mercaptopurine and prednisone, the total leucocyte count had fallen to 2,300 per cu. mm., a very occasional blast cell only being present in the peripheral blood and the bone marrow. To our surprise, approximately 35 per cent of red cells were now agglutinated by anti-A sera (group B). There was no agglutination by Dolichos anti-A_1, the agglutinable cells appearing to behave, therefore, as normal A_2 cells. The unagglutinated cells, separated by differential agglutination, continued to absorb anti-A.

The partial reversion towards normal which accompanied the hæmatological remission was also paralleled by a clinical remission. The 6-mercaptopurine was discontinued and 7 weeks later, when the total leucocyte count had risen to 7,900 per cu. mm. (blast cells, 790), the percentage of agglutinable A cells had fallen to 20 per cent. The clinical remission terminated abruptly 4 weeks later and just before death, with a blast cell count of 23,600 per cu. mm. (total leucocytes 62,000); 8 per cent only of red cells in peripheral blood and marrow were now agglutinable.

During the period of observation, there was no change in the patient's anti-B agglutinins and no irregular anti-A antibodies could be demonstrated *in vitro*. *In vivo*, however, 1 ml. of group A_1 red cells labelled with chromium-51 survived for a much shorter time than similarly labelled group O cells. When transfusion was necessary, therefore, group O packed cells were selected in preference to group A. Unfortunately, circumstances prevented a repeat injection of labelled group A and O cells, and we were unable to establish definitely, therefore, that the blood-group change was accompanied by an unexpected intolerance to small amounts of group A_1 blood. No group A substance was found in the serum or saliva, even using a group O anti-A serum which agglutinated A_x cells. Tests of the two types of red cells present, after separation, for other blood group antigens (M,N,S, P, H, Le^a, C,D,E,c,e, Jk^a, *Kell*, Fy^a) showed no differences, except that, whereas both types of red cells were agglutinated by anti-H (*Ulex*) and anti-Le^a, the cells inagglutinable by anti-A reacted considerably more strongly with the anti-H but slightly less strongly with the anti-Le^a than did those agglutinable by anti-A.

It is interesting to note that in this case, as in those reported by Van Loghem and his colleagues, and by Stratton *et al.*, the red cells were Le^a-positive and the patient was a non-secretor of A and H substance. These three antigens are chemically related, and in the four cases now on record in which the A antigen has been modified by disease, the patient's underlying illness was leukæmia. The case reported by Stratton *et al.* presented as a hypoplastic anæmia, but terminated as a leukæmia (Stratton, F., personal communication, 1959). Our case was established as a monocytic leukæmia and remained as such throughout its course. No explanation can yet be given concerning the mechanism of the changes in blood group, though Haddow's[4] hypothesis of genetic and enzymatic deletion in neoplasias, including leukæmia, by physical, chemical or viral agents might provide an explanation for a similar action on genes governing the formation of the A, H and Le^a antigens.

The patient's blood group was not known prior to his illness. His mother is A_1 and his father O. Family studies have failed to demonstrate the mother's genotype; but the patient's only brother and his three maternal aunts and uncles are A_1 or A_1B. By inference, therefore, it is more likely that the patient's group was A_1 rather than A_2. It is most unlikely that it was A_x, since the agglutinable cell population behaved as normal A_2 cells.

We wish to thank Dr. G. Mather for the opportunity to investigate this patient, and Drs. N. F. W. Brueton and F. Freundlich for their assistance in the investigations.

Absorption of Radioiodine through the Bladder-Wall in the Rabbit

NUMEROUS studies have been made of the absorption of a variety of substances through the bladder-wall in frogs, rabbits, canines and humans[1-8]. We report below a study of some factors influencing the absorption of iodide ions in rabbits.

Male rabbits weighing 2–3·5 kgm. were used, and experiments were carried out under urethane anæsthesia. The rabbits were catheterized with Nélaton catheters (diam. 12–13 Charrière), and urine samples were shown to be free of hæmoglobin. After irrigation of the bladder with isotonic saline, radioiodine or a compound of it was introduced into the bladder. Blood samples were collected after 0, 20, 40, 60 and 80 min. from the marginal ear vein. Beta-activity of the samples was measured with a Geiger–Müller counter.

(1) In 3 animals 10–20 ml. isotonic saline containing 0·36–2·0 mc. of sodium iodide labelled with iodine-131 was left in the bladder for 45 min. After 24 hr. the thyroid glands showed activities of 7–23 μc. Approximate determinations of gland activities were carried out on a phantom with the help of a scintillation counter. The results demonstrate absorption of radioiodine through the bladder-wall.

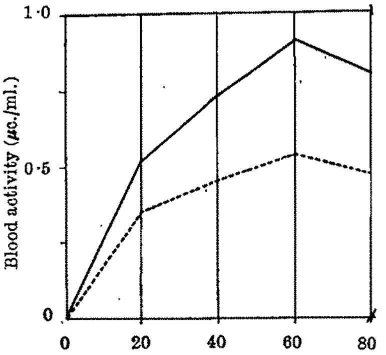

Fig. 1. ———, 1·2 osmolar sodium iodide solution; – – – –, 30 milliosmolar sodium iodide solution

(2) In 4 rabbits 5 ml. isotonic saline containing 20 mgm. radioiodinated human serum albumin with an activity of 700 μc. was introduced into the bladder and left for 60 min. In two animals 1 mgm. hyaluronidase was added to the solution. Whole samples were rendered free from protein with 15 per cent trichloracetic acid. Measurements made on the filtrate and on the precipitate did not show significantly higher values than in group 1. These results indicate that molecules of the size of serum albumin are relatively unabsorbed through the bladder-wall.

(3) In 3 rabbits 1 mgm. adrenaline was introduced along with 5 ml. isotonic saline containing 1 mc. radioiodine. No significant differences were found in comparison with 3 controls. This showed that the addition of adrenaline did not alter in any significant way the absorption of radioiodine under the experimental conditions described.

(4) In 9 rabbits 5 ml. of a 30 milliosmolar non-radioactive sodium iodide solution was used, and in a further 9 animals a 1·2 osmolar sodium iodide solution was applied, 1 mc. of labelled sodium iodide being added to each solution. The activities of blood samples were higher in all animals receiving the hypertonic solution. Mean activity curves of both groups are shown in Fig. 1. The results show a dependence of absorption on concentration gradient.

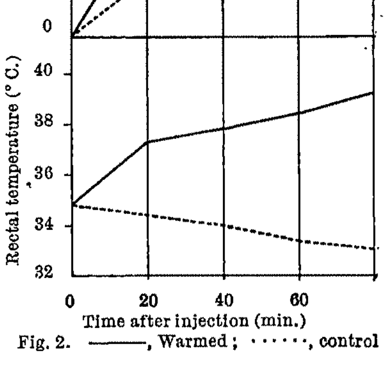

Fig. 2. ———, Warmed; ······, control

(5) In 8 rabbits 5 ml. of 0·3 osmolar sodium iodide with activity of 1 mc. was introduced into the bladder. In 5 animals the lower part of the body was heated by short-wave diathermy or by infra-red rays. The average rise of rectal temperature amounted to 4° C. after 60 min. Curves of mean blood activity and rectal temperature of both groups are shown in Fig. 2. These findings demonstrate a dependence of absorption on the rectal temperature and therefore on the rate of blood supply to the bladder-wall.

We conclude that significant re-absorption of urinary iodide occurs through the bladder-wall and suggest that local bladder conditions should be taken into account in quantitative physiological studies with this ion.

Disturbance in the Pattern of Serum Proteins in Experimental Atherosclerosis and its Prevention

IT has recently been reported by two of us[1,2] that various kinds of experimental atherosclerosis, indicated by great increase in the total cholesterol/lipid phosphorus ratio in the blood and tissues of animals, can be prevented by hydrolysed glucose–*cyclo*acetoacetate, a product formed by condensing glucose with acetoacetate. It was shown by Van Dommeleu and Schutt[3] that albumin fraction is low and γ-globulin is high in diabetic coma, and Klinger[4] observed that when diabetes is accompanied with severe hypertension, there is a further decrease of albumin and a sharp increase of γ-globulin. As according to Dawber *et al.*[5] hypertension is usually associated with the incidence of atherosclerosis, attempts were made to study the protein pattern in the serum of saturated fat-induced atherosclerotic animals and in those prevented by essential fatty acids, inositol, vitamin B_{12} and glucose–*cyclo*acetoacetate (hydrolysed).

Thirty-five male albino rabbits weighing on an average 1·2 kgm. were divided into seven equal groups and caged individually. The animals of group 1 were fed with a laboratory stock diet consisting of casein 20 gm., sucrose 30 gm., wheat flour 39 gm. groundnut oil 6 gm., Hawk Oser salt mixture 5 gm. and all the vitamins of B complex group and vitamins A and D in requisite quantities. The animals of all the remaining groups were given saturated fat (20 per cent of the diet) in place of groundnut oil. The animals of group II were taken as control while those of groups III and VI were injected with a daily dose of 300 mgm./kgm. and 1·5 μgm./kgm. body-weight of glucose–*cyclo*acetoacetate (hydrolysed) and vitamin B_{12} ('Macrabine', Glaxo) respectively, and those of groups IV, V and VII were given 1 gm. of linoleic, linolenic acid and inositol respectively along with the saturated fat diet.

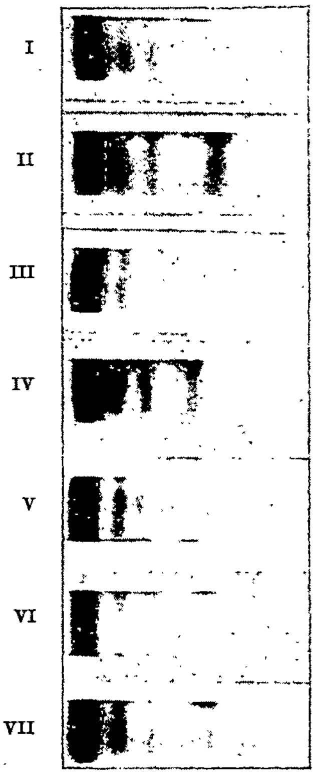

Fig. 1. Agar electrophoresis patterns of serum proteins of normal, saturated fat-induced atherosclerotic and treated animals. (I) Normal; (II) saturated fat-induced; (III) kept on saturated fat and injected with glucose-*cyclo*acetoacetate (hydrolysed); (IV) linoleic acid supplemented; (V) linolenic acid supplemented; (VI) kept on saturated fat and vitamin B_{12} injected; (VII) inositol supplemented

The experiment was carried on for a period of 12 weeks. The blood samples were drawn from the marginal ear veins of the rabbits, and the serum obtained by the usual method was used for electrophoretic studies.

The agar electrophoresis technique developed by Giri[6] was employed for the separation and staining of serum proteins, amidoschwarz 10*B* in 100 ml. of solvent mixture of the composition methanol/acetic acid/water (40 : 10 : 50) being used for staining.

Albumin, α-, β- and γ-globulins in the serum were found to be clearly separated on the agar plate. Photographs of the serum patterns of the rabbits of normal and experimental groups are shown in Fig. 1. The electrophoresis of serum samples was run under exactly identical conditions. From pattern II, it is evident that the γ-globulin fraction of the rabbits kept on high saturated fat diet increased appreciably with a simultaneous decrease in the albumin fraction as compared to pattern I of normal rabbits. On the other hand, in the patterns IV (linoleic acid supplemented), V (linolenic acid supplemented) and VII (inositol supplemented), it has been observed that the γ-globulin fractions, although found to be less than that in pattern II (kept on saturated fat diet), the amount was not as low as in normal animals. It is further observed from pattern IV that the effect of linoleic acid in suppressing the rise of γ-globulin fraction was not so pronounced as in the case of linolenic acid and inositol (patterns V and VII respectively). The serum pattern of animals injected with vitamin B_{12} (pattern VI) was found to show a greater decrease in γ-globulin fraction and increase in albumin fraction than those of patterns IV, V and VII; but still the pattern was not normal. However, the serum protein pattern III of rabbits injected with hydrolysed glucose-*cyclo*-acetoacetate is found to be very similar to the normal pattern I.

From the above findings, the γ-globulin fraction has been increased in the animals with atherosclerosis induced by a saturated fat diet that could be corrected by glucose–*cyclo*acetoacetate (hydrolysed), which has already been shown to contain 1 : 2 dienol glucose[7] and to cause prevention of experimental diabetes of various kinds[8-10]. It has recently been suggested by Beveridge *et al.*[11] that the serum cholesterol lowering effect of corn oil is due to something besides the unsaturated fatty acid glycerides of the corn oil, and Grande *et al.*[12] have shown that such a factor (*X*) is present in the unsaponifiable fraction of corn oil. It is quite possible that such *X* factor may be in some way or the other related to glucose–*cyclo*acetoacetate or its hydrolysed product.

Study of Adenovirus Antigens by Immunoelectrophoresis

Multiplication of adenoviruses in susceptible cells is accompanied by the formation of antigenic materials which can be distinguished from virus particles. These materials have been detected by different serological techniques including complement fixation[1,2], sensitized red-cell agglutination[3], conglutinating complement adsorption[4] and gel diffusion precipitation[5]. Part of the non-virus material is responsible for the early cytopathic[6] and cell-detaching[7] properties which are abolished by incubation with trypsin or by addition of homologous antiserum, a result suggesting that they are mediated by an antigenically specific protein.

Observations with the gel diffusion precipitation technique have shown at least three antigens in partially purified preparations of adenovirus type 5. The conditions under which precipitation occurs make it clear that these antigens are considerably smaller than intact virus particles[8]. Results of experiments in which the three precipitating antigens were separated by electrophoresis are presented in this communication.

The virus material used consisted of the prototype strain of adenovirus type 5 propagated in HeLa cells

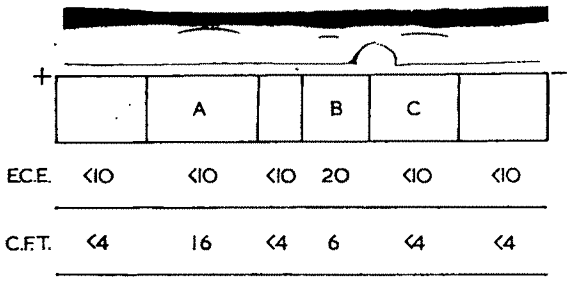

Fig. 1. Immunoelectrophoresis of adenovirus type 5 antigen tested against homologous antiserum. Top, photographic print of precipitation lines; bottom, early cytopathic effect (E.C.E.) and complement-fixing titres (C.F.T.) of extracts from agar sections

and partially purified by the method of Gessler *et al.*[9] using the fluorocarbon compound 'Arcton 63' as previously described[10]. Adenovirus type 5 antiserum was obtained from a rabbit with a latent infection[11]. The serum reacted strongly with the virus antigen in complement fixation and gel diffusion precipitation tests, while no reactions with normal HeLa cell antigens could be demonstrated by either technique.

Immunoelectrophoresis[12] was performed in a gel[8] composed of 2 per cent washed agar in borate–phosphate buffer (μ = 0·05 *p*H 8·5)[13]. The same buffer was present in the electrode baths and on the lint connecting strips. Electrophoresis of 0·1-ml. samples of the antigen was conducted at room temperature with a current of 20 m.amp. for 7–8 hr. Antiserum placed in pre-formed side channels was allowed to react with the antigenic material at 4° C. in a moist chamber. After 5–6 days the gel was washed in saline, dried, stained with naphthalene black and made into a permanent preparation.

Three antigens with different electrophoretic mobilities could be demonstrated (Fig. 1). These will be designated antigens *A*, *B* and *C*. In order to characterize the antigens they were eluted from the agar. After electrophoresis the agar was cut in half by an incision through the origin along the plane of migration. One half was treated with antiserum to show the position of the antigenic components. The other half was cut into sections according to the expected position of the antigens. Each section was cut into small pieces and suspended in 1 ml. of normal saline at 4° C. for 4 days. The saline extracts were then tested for complement fixation against an optimal dilution of homologous antiserum and for early cytopathic action on HeLa cells, the results being read after overnight incubation of the cultures[6], Complement-fixing activity was detected in fractions corresponding to antigens *A* and *B*. The titres obtained were relatively low, suggesting poor recovery, which may explain the negative result given by the third antigenic component.

Early cytopathic activity was associated with antigen *B* only, although the complement-fixing activity of this component was less than that of component *A*. Further evidence that antigen *B* is responsible for the early cytopathic action is provided by the effects of trypsin treatment of the virus material. This abolishes the early cytopathic effect[6] and brings about only a slight reduction in complement-fixing titre[8]. When immunoelectrophoresis is carried out on trypsin-treated material, components *A* and *C* are unaffected but component *B* is no longer demonstrable.

The relationship of these antigenic components to non-viral crystalline material appearing in ultra-thin sections of adenovirus-infected cells[14] remains to be established.

Effect of Tranquillizing Agents on the Resistance of Rats to Histamine Stress

IN view of the long-continued interest in the relationship of histamine to metabolic processes and disorders, most particularly allergy and psychosis, the present investigation sought to explore the effects of prolonged administration of various tranquillizers on response in the rat to histamine, including effects on such variables as histamine *LD*50, mortality and alterations in body-weight.

Male albino Wistar rats (80–90 per test group), averaging 100 gm., were injected subcutaneously with 1 ml. aqueous preparations of different tranquillizers daily for a two-week period. Control rats received 1 ml. daily injections of distilled water. On the fifteenth day, test and control groups were injected intraperitoneally with various amounts of histamine phosphate. The challenging doses ranged from 300 to 1,100 mgm./kgm. body-weight. Finney's[1] method of probit analysis was used for calculating the *LD*50 values and dose–response lines.

Table 1 presents the various tranquillizing agents studied, their concentrations and the histamine *LD*50, body-weight and mortality-rate results. The study indicated that hydroxyzine hydrochloride, reserpine and promazine hydrochloride are effective in preventing death from histamine shock, whereas azacyclonal hydrochloride has an intermediate effect and chlorpromazine hydrochloride a negligible influence.

Statistical analyses of the results for histamine *LD*50 revealed that hydroxyzine hydrochloride and promazine hydrochloride produce significant increases in resistance of the rat to histamine and the increase produced by reserpine approached statistical significance at the 0·05 confidence-level. Additional calculations revealed that none of the differences between the slopes of the various test and control dose–response lines were statistically significant.

As is apparent in Table 1, all tranquillizing agents studied caused significant declines in the terminal

Table 1. Effect of Tranquillizing Agents on Mortality-Rates, Body-weight and *LD*50 Values

Agent	Concentration (mgm./ml.)	Tranquillizer mortality (per cent)	Terminal body-weight	Difference between test and control (per cent)	*P* value	*LD*50 (mgm./kgm.)	Difference between test and control (per cent)	*P* value
Control	1 ml. distilled water	0	168·7 ± 1·3			599·3 ± 40·2		
Chlorpromazine hydrochloride	0·1	3·3	151·3 ± 2·6	−10·3	< 0·001*	606·4 ± 48·1	± 1·2	0·88
Azacyclonal hydrochloride	1·0	0	159·9 ± 2·2	−5·2	0·05*	665·3 ± 51·0	± 11·0	0·20
Promazine hydrochloride	0·1	12·5*	152·8 ± 0·7	−9·4	< 0·01*	700·4 ± 39·8	± 16·9	0·03*
Reserpine	0·007	26·7*	145·7 ± 2·9	−13·6	< 0·001*	699·3 ± 53·3	± 16·7	0·08
Hydroxyzine hydrochloride	0·07	18·9*	135·7 ± 3·1	−19·6	< 0·001*	816·6 ± 35·5	± 36·3	0·001*

* Difference between test group and control is significant.

body-weights of the treated rats in the dosages and time patterning of these experiments. Prior to histamine administration, all tranquillizers except azacyclonal hydrochloride and chlorpromazine hydrochloride caused significant increases in the mortality-rates of the rats during the two-week period. A preliminary study with reserpine concentrations of 0·1 mgm./ml. had to be discontinued after 7 days due to the excessive mortality-rate. Although Gaunt *et al.*[2] do not indicate the mortality-rates caused by various reserpine concentrations, they do state : "In work with normal rats, we found that 10 mcgm./100 gm./day of reserpine was not well tolerated when given for prolonged periods of time. It interfered with growth, appetite, etc., and we considered it unsuitable for chronic use".

In conclusion, hydroxyzine hydrochloride, reserpine and promazine hydrochloride when administered for two weeks caused marked increases in resistance to histamine as measured by histamine *LD*50. Except for azacyclonal hydrochloride, increase in resistance to histamine was associated with loss in body-weight and increase in pre-histamine administration mortality.

Slow Contraction of Smooth Muscle produced by Human Plasma

HUMAN blood plasma or serum produces a delayed, slow contraction of the isolated ileum of the guinea pig. This effect is best observed with dialysed plasma, since dialysis eliminates the quick-contracting agents[1]. Recently, Gabr[2] described the isolation from the *G*.2 fraction of human plasma[3] of a fatty acid which has an effect similar to that of plasma on the isolated ileum of the guinea pig.

Preliminary experiments carried out on processed human plasma for transfusion purposes showed that storage at room temperature of liquid plasma[4] changes the character and potency of its contracting effect on the isolated ileum. It has also been observed that processing of the plasma with kaolin[5] and pooling of the plasma derived from stored banked blood produce similar changes. These observations may be summarized as follows :

(1) Storage of liquid plasma at room temperature under sterile conditions for six months decreases its toxicity for the isolated ileum of the guinea pig. The muscle contraction starts more slowly, and the recovery of the smooth muscle takes a longer time after repeated washings of the preparation with the test fluid (Tyrode solution).

(2) Processing of human plasma with kaolin considerably decreases its effect on the isolated ileum. Like normal plasma, kaolin-processed plasma becomes less toxic when stored for six months at room temperature.

(3) Pooled human plasma is less active on the isolated ileum than single-donor plasma. This effect seems to depend on the size of the plasma pool. Plasma pools derived from ten bottles of banked blood were found to be less active on the isolated ileum than plasma pools derived from seven bottles of banked blood. Again, the latter pools were less active than smaller pools derived from three blood bottles. In the case of big plasma pools, the onset of muscle contraction was much slower, and the summit of contraction often declined a few seconds after.

(4) No relation could be found between the toxicity of pooled plasma and the group types of the blood bottles from which the plasma was separated.

(5) The effect of pooled plasma on the isolated ileum of the guinea pig decreases slightly after standing for one week at room temperature prior to freeze-drying.

Barbiturate Nystagmus and the Mechanisms of Visual Fixation

WHEN a human subject follows a moving object with his eyes, they perform movements of two types[1,2]. There are smooth pursuing movements and rapid jerky changes of position known as saccades. Fig. 1*a* is a record of the position of an eye which is fixating a small spot of light in an otherwise totally dark room. Up to time $t = 0$ this spot of light has remained stationary in front of the subject. At time $t = 0$ it begins to move horizontally with a uniform velocity of 3 deg./sec. It can be seen that the eye remains stationary for about 150 msec., and then begins to move smoothly in pursuit of the spot. When about 300 msec. has elapsed since the spot began to move, the eye makes a saccadic movement at the end of which it is again looking directly at the spot. Thereafter the eye continues to move with the same velocity as the spot, and fixation is as good as it is when the spot is not moving.

It is known[3] that moderate doses of barbiturates produce a nystagmus in normal subjects when the eyes are deviated to look at an object which is displaced from the forward direction. The slow phase of the nystagmus is towards the central position and the quick phase is towards the object. Fixation on an object directly in front of the subject is disorganized and random movements of the eyes occur.

It is of interest to know how barbiturates will affect the way in which the eyes pursue a moving object. Fig. 1*b* shows a record taken on the same occasion as Fig. 1*a* after the intravenous administration of 100 mgm. of 'Pentothal' in the course of 8 min. It can be seen that the ability of the eye to make smooth pursuing movements is abolished and it proceeds in a succession of jerks each one refixating the escaping spot.

A few further observations about visual tracking will permit an explanation of the effects of barbiturates. Smooth eye-movements are caused by the movement of the spot of light and not by its position. Fig. 2 shows the response of the eye to a spot which, initially stationary and straight ahead, moves instantly to the left and then proceeds with uniform velocity towards the right. The eye starts to move smoothly to the right although this is away from the position of the spot. The mechanism for smooth movements is aiming at achieving a stationary image on the retina irrespective of error in the position of fixation. Such an error is then corrected by a jerk provided that it exceeds about 0·1 deg. and some 200 msec. has elapsed since the previous jerk.

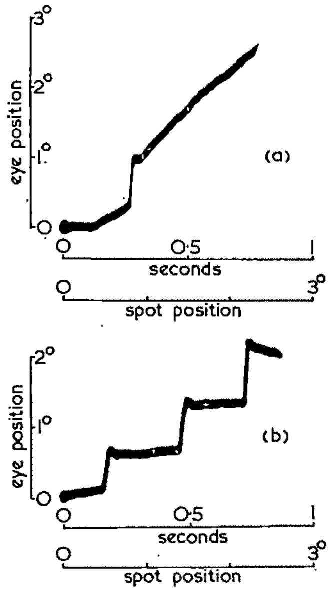

Fig. 1. Records of the eye-movements caused by watching a spot moving with constant velocity (*a*) before and (*b*) after the administration of 100 mgm. 'Pentothal' intravenously

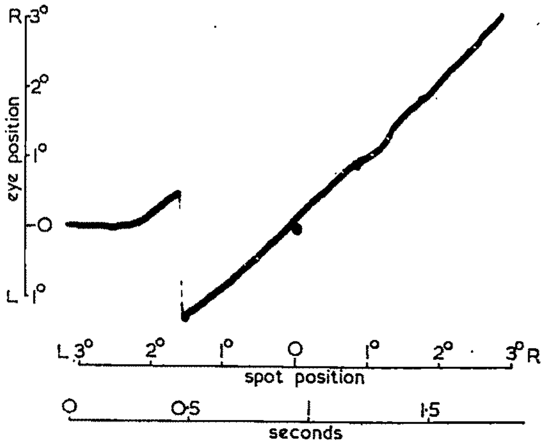

Fig. 2. Record of the eye-movement caused by watching a spot which is suddenly given a change of position in one direction and a velocity in the opposite direction

It is probable that no other mechanism is involved in fixating a stationary spot. When this is straight ahead, the eyes will be held stationary by the smooth mechanism except for very slow drifts in either direction[4] at velocities which are too slow for the eye to detect. When a sufficiently large error in position accumulates it will be corrected by a jerk. When the fixation spot is to one side the same things happen except that the drifts tend to be towards the centre[4].

Barbiturates abolish the smooth mechanism. Therefore, on forward fixation, spontaneous smooth movements of the eyes will not be prevented, and apparently random movements will occur with many refixation jerks. On deviated fixation these uncorrected smooth movements will be towards the centre with large outward refixation jerks at a rate up to 5/sec., this being the barbiturate nystagmus.

A description of the method used for recording eye movements and further details will be published elsewhere.

Inhibition of Sensitiveness to Nicotine of Rabbit Aorta by Reserpine, Hexamethonium, Ethyl Flavone-7-Oxyacetate and Other Compounds

Burn and Rand[1] demonstrated that some spastic effects of nicotine on aortic strips can be abolished by a prophylactic treatment with reserpine. The present investigation was conducted in order to study

Table 1. SUBSTANCES WHICH PROVOKE A SUBMAXIMAL CONTRACTION OF THE AORTIC CHAIN

Substance	Concentration (μgm./ml.)
Adrenaline (on aortic chains of normal rabbits)	0·4–0·8
Adrenaline (on aortic chains of reserpine-treated rabbits)	0·2–0·4
Acetylcholine chloride	2–10
Histamine dihydrochloride	0·25
5-Hydroxytryptamine	1
Barium chloride	>150
Nicotine sulphate (on the fresh aortic chain)	~150
Nicotine sulphate (on the aortic chain sensitized by adrenaline)	2·5–15

how reserpine or other drugs are able to prevent the spastic activity of nicotine on this blood vessel.

The experiments were carried out on chains obtained by binding together about eighteen 2-mm. wide rings cut from the thoracic aorta of a rabbit. The chains were suspended in Ringer–Locke solution, aerated with oxygen at 37° C., and the contractions recorded. The active concentrations of nicotine and some other substances, able to cause a contraction of the aortic chain, are reported in Table 1. Nicotine itself, scarcely active on the fresh preparation, becomes very active after 2–4 contractions induced by adrenaline, histamine or acetylcholine.

Up to a concentration of 200 μgm./ml., nicotine did not cause any contraction if 0·5 mgm./kgm. reserpine had been daily administered subcutaneously, in the four days before the experiment, to the rabbits the aortic chains of which were used. This treatment did not affect the spastic activities of the other agents listed in Table 1.

On the other hand, reserpine added directly to the perfusion fluid up to a concentration of 3 μgm./ml. did not affect the sensitiveness of chains to nicotine; with higher concentrations an interference due to solvents was observed.

In order to investigate the mechanism of the action of nicotine, the activities of some antagonistic drugs were tested against the contractions induced by nicotine (Table 2) and some other drugs (Table 3).

Table 2. INHIBITION OF NICOTINE CONTRACTIONS OF THE AORTIC CHAIN

Substance	*ED*50 (μgm./ml.)*
Atropine sulphate	5
Dihydroergotamine	16
Hexamethonium	0·25
Pyrilamine hydrochloride	2·5
Reserpine	>3†
Papaverine hydrochloride	40
Ethyl flavone-7-oxyacetate	40
Aminophylline	160

* Concentration that inhibited by 50 per cent the contractions of the aortic chain due to 5 μgm./ml. of nicotine sulphate.

† With higher concentrations an inhibition due to the solvents was observed.

Table 3. INHIBITOR ACTIVITY AGAINST SOME STIMULATING AGENTS

Stimulating agent	Inhibitor	*ED*50 of the inhibitor (μgm./ml.)
Acetylcholine chloride, 5 μgm./ml.	Atropine sulphate	0·02
Adrenaline, 0·5 μgm./ml.	Dihydroergotamine	15
Adrenaline, 0·5 μgm./ml.	Hexamethonium	>150
Histamine dihydrochloride, 0·25 μgm./ml.	Pyrilamine hydrochloride	0·001

Since atropine and pyrilamine are much more effective in counteracting acetylcholine and histamine-induced spasm than nicotine contractions, the latter probably are not due to an acetylcholine or histamine liberation. On the other hand, dihydroergotamine antagonizes adrenaline-induced contractions at the same concentration as nicotine-induced contractions, and therefore it is possible that arterial nicotinic spasm is mediated through adrenaline or adrenaline-like substances. This conclusion is also supported by the characteristics of the activity of reserpine, which is able to inhibit the sensitivity to nicotine only if administered to the animals for some days, while the same drug is inactive if put directly in contact with the aortic chain. Probably, when chronically administered, reserpine depletes the aorta[1] as well as some other organs[2] of catecholamines and therefore nicotine cannot liberate adrenaline-like substances in the aortic chains of animals treated with reserpine.

The high inhibitory activity of hexamethonium against nicotine contractions could be easily explained if aortic sympathetic ganglia were stimulated by nicotine and blocked by hexamethonium. Since aortic sympathetic ganglia have not yet been demonstrated, an antagonistic effect of hexamethonium on a direct liberation of sympathetic substances from the cells due to nicotine may be possible.

The inhibiting mechanism of papaverine and ethyl flavone-7-oxyacetate, two powerful spasmolytics and coronary dilators, is probably a myotropic one.

As a result of this work, reserpine therapy in vascular diseases due to smoking is suggested. A combined treatment with some other nicotine contraction inhibitors, particularly with ethyl flavone-7-oxyacetate, might also be of some value, because this drug, compared with the others listed in Table 2, has a very low general toxicity.

PLANT PHYSIOLOGY

Absence of Gibberellin-like Substances in Filtrates of *Marasmius perniciosus* Stahel (Witch Broom Disease of Cacao)

CACAO plants (*Theobroma cacao*) infected with *Marasmius perniciosus* produce excessive and abnormal branching, a condition known as witch broom disease. It has been suggested by Brian[1] that symptoms may be caused by the production of growth-stimulatory or auxin-like substances by the pathogen. The morphological effects of gibberellic acid sprayed on cacao seedlings suggested that the 'brooming' effect of *M. perniciosus* might be caused by the production *in vivo* of gibberellin-like compounds by the fungus (Nichols, unpublished data).

This communication describes an attempt made to detect the production of growth-stimulatory substances or gibberellin-like compounds from a strain of *M. perniciosus* freshly isolated from an infected cacao tree, by the application of culture filtrates and expressed cytoplasmic constituents to cacao and rice seedlings (*Oryza sativa*). These two test species were chosen because cacao is one of the host plants of *M. perniciosus*, and rice is known to respond to gibberellic acid. Plants treated with the uninoculated medium were used as controls, and plants treated with culture filtrates of *Fusarium moniliforme* grown in the same medium were used as an index of the production and behaviour of gibberellic acid. Preliminary experiments with gibberellic acid confirmed that rice seedlings responded to application of the solution of the acid under the conditions of our test.

In order to prepare culture filtrates, the organisms were grown on the following medium, which gave good growth: hydrolysed molasses, 20·6 gm./l. total sugar; ammonium sulphate, 3 gm./l.; potassium dihydrogen phosphate, 3 gm./l.; 'Marmite', 5 gm./l. The medium was adjusted to *p*H 6·3 and dispensed in 100-ml. amounts in indented 250-ml. conical flasks. The cultures were grown on a rotary shaker at tropical room temperature (26–29° C.) for 20 days, by which time sugar utilization was complete (97 per cent). The cultures (20 flasks) of each organism were combined and filtered through sintered glass, after which the sugar concentration in the clear filtrates was restored to that in the uninoculated medium by the addition of equal amounts of glucose and fructose. The *p*H was also adjusted to its initial value. The culture filtrates and control medium were concentrated eight-fold by evaporation under reduced pressure at 40° C.

The effect of the concentrated filtrates on growth was examined by application of 0·1-ml. amounts to the terminal buds of cacao seedlings about 4 weeks from germination, grown in seed boxes. Each solution was tested on 12 plants. The plants were treated twice-weekly at 3- and 4-days intervals for a total period of 4 weeks. Concentrated and unconcentrated filtrates were tested in this manner. The *Fusarium* filtrates gave a marked elongation of the stem by typical internode elongation as compared with the control plants, but no effect either stimulatory or inhibitory was observed with the *Marasmius* filtrates. Similar results were obtained when the filtrates were applied to rice seedlings.

Despite the negative results with cultures grown *in vitro*, it remained possible that the substances responsible for the growth abnormalities of cacao were produced by the *Marasmius in vivo* in the host plant. This possibility was examined by treating seedlings with an extract of infected cacao tissue. The extract was prepared by macerating freshly collected witch broom branches (250 gm.) in a Waring blendor with a little water and expressing the mucilaginous pulp through several layers of cotton gauze. The filtrate was concentrated approximately ten-fold by evaporation to a thick gel in a freeze-drying apparatus. Cacao seedlings were treated by application of the extract to the stem just below the terminal bud. Some of the seedlings were pricked after the initial application to ensure entry of the extract into the plants. Treatment was continued twice weekly for 4 weeks. The extract had no effect whatsoever on the growth-rate relative to untreated control plants. These experiments suggest that *M. perniciosus* does not produce a detectable growth-stimulatory substance similar to gibberellic acid under the conditions of the culture and test whereas *F. moniliforme* does.

The strain of *F. moniliforme* (N.R.R.L. 2284) was kindly supplied by Dr. C. W. Hesseltine and the gibberellic acid by Dr. P. W. Brian.

Interaction of Magnesium and Adenosine Diphosphate in Photosynthetic Phosphorylation

A critical ratio of magnesium and the adenosine phosphates has been observed in several enzymically catalysed reactions. Hers[1] demonstrated that maximal activity in the hexokinase and fructokinase reactions occurred when the magnesium/adenosine triphosphate ratio was one. The rate of formation of adenosine diphosphate from adenosine monophosphate and adenosine triphosphate, catalysed by myokinase, was maximal when the magnesium/adenosine triphosphate ratio was one; in the reverse reaction, maximal activity was observed when the ratio was one half[2]. A definite stoichiometry between adenosine triphosphate and manganese also has been found, for Lowenstein[3] observed that maximal activity in a non-enzymic transphosphorylation occurred when the manganese/adenosine triphosphate ratio was approximately 1·7.

Arnon *et al.*[4] reported that magnesium enhanced photosynthetic phosphorylation. Avron *et al.*[5] have given results of the saturation of photosynthetic phosphorylation by magnesium and adenosine diphosphate in the presence of constant amounts of adenosine diphosphate and magnesium, respectively. It may be calculated from their results that in the presence of 1·5 μmoles adenosine diphosphate the system was saturated by 2·5–3 μmoles magnesium; in the presence of 5 μmoles magnesium the system was saturated by 2·25–2·5 μmoles adenosine diphosphate. Thus saturation was reached when the magnesium/adenosine diphosphate ratio was two. We have performed additional experiments, the results of which indicate that a definite ratio of magnesium and adenosine diphosphate is necessary for optimal photosynthetic phosphorylation.

Chloroplasts were prepared by grinding 25 gm. of spinach leaves, from which the petioles and mid-ribs had been removed, with sand and 25 ml. homogenizing solution in a mortar. The homogenizing solution was 0·02 *M* with respect to *tris* buffer *p*H 8·0, 0·3 *M* with respect to sucrose, and 0·004 *M* with respect to sodium chloride. Cellular debris was removed by filtering through cheese-cloth. The juice was centrifuged at 100*g* for 1 min., and this supernatant was centrifuged for 7 min. at 1,000*g*. The sedimented chloroplasts were suspended in 5 or 10 ml. of the homogenizing solution. These operations were performed at 5° C. Chlorophyll concentration was determined by Arnon's method[6].

The phosphorylation reaction was performed in Thunberg tubes. The reaction mixture contained 50 μmoles *tris* buffer *p*H 8·0, 80 μmoles sodium chloride, 20 μmoles dipotassium hydrogen phosphate, 10 μmoles ascorbate, 0·1 μmole flavin mononucleotide, 0·1 ml. chloroplast preparation (50–100 μgm.

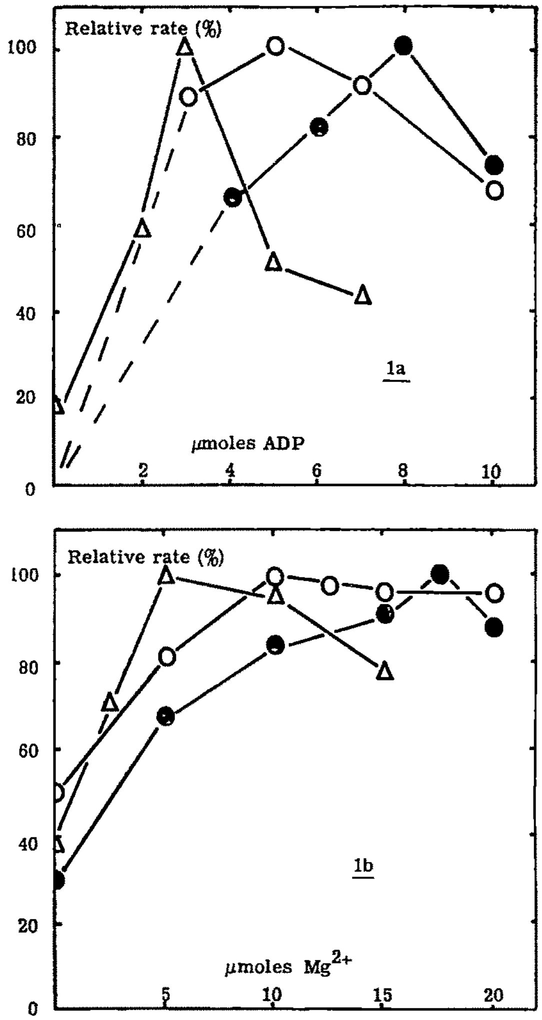

Fig. 1. *a*, Effect of concentration of adenosine diphosphate on photosynthetic phosphorylation. △, 5 µmoles magnesium; ○, 10 µmoles magnesium; ●, 15 µmoles magnesium. The rates corresponding to 100 per cent for △, ○ and ● were 70, 140 and 110 µmoles phosphate esterified/mgm. chlorophyll/hr., respectively. *b*, Effect of concentration of magnesium on photosynthetic phosphorylation. △, 3 µmoles adenosine diphosphate; ○, 5 µmoles adenosine diphosphate; ●, 8 µmoles adenosine diphosphate. The rates corresponding to 100 per cent for △, ○ and ● were 155, 100 and 104 µmoles phosphate esterified/mgm. chlorophyll/hr., respectively

chlorophyll), magnesium sulphate, adenosine diphosphate and water in a total volume of 3·0 ml. After trials had showed that phosphorylation occurred aerobically as well as anaerobically, all reactions were run in an atmosphere of air. The reaction vessels were held in a water-bath at 15° C. Illumination was provided by 150-watt reflector flood lights (intensity measured with a barrier layer photocell was approximately 1,800 foot candles). The reaction was allowed to proceed for 20 min., after which 0·5 ml. 20 per cent trichloracetic acid was added to each tube. Trichloracetic acid was added to control vessels either directly after the addition of chloroplasts or after 20 min. in darkness. The nucleotides were separated from inorganic phosphate by the method of Crane and Lipmann[7]. Phosphate was determined by the method of Taussky and Shorr[8]. Rates of phosphorylation were calculated from the disappearance of inorganic phosphate. The increase of organic phosphate was determined by hydrolysing the adsorbed nucleotides, but this increase was usually 5–20 per cent less than the amount of inorganic phosphate disappearing.

Fig. 1*a* shows the effect of adenosine diphosphate concentration on the rates of photosynthetic phosphorylation in the presence of three concentrations of magnesium. In the three cases the optimal rates of phosphorylation were observed when the magnesium/adenosine diphosphate ratio was 2. Fig. 1*b* shows the influence of magnesium concentration on the rates of photosynthetic phosphorylation in the presence of three concentrations of adenosine diphosphate. In these experiments also, optimal activity was observed when the magnesium/adenosine diphosphate ratio was 2. Magnesium usually showed a saturation effect ; but in some instances inhibition was observed at higher concentrations.

It is clear that a definite magnesium/adenosine diphosphate ratio is necessary for optimal photosynthetic phosphorylation. Magnesium may affect more than one reaction in the process of photosynthetic phosphorylation; however, information on the overall reaction still is insufficient to evaluate the significance of the magnesium/adenosine diphosphate ratio of two.

Synergistic Effect of Zinc and Gibberellin

Dwarf beans (*Phaseolus vulgaris*) were sown in John Innes seed compost and, when emergence had occurred, the seedlings were transplanted into 2½-in. pots using the John Innes potting compost.

The plants were put in a growth room maintained at 60° F. and illuminated for 15 hr. a day with a bank of fluorescent lights giving 500–600 foot candles at the primary leaf surface of the beans. The plots were arranged in three 4 × 4 Latin squares, and 0·5 ml. gibberellic acid solution containing 500 mgm./l. 'Gibrel' was applied to the leaves of half the plants when elongation of the apical bud had commenced. ('Gibrel' is the potassium salt of gibberellic acid as produced by Merck and Co., Rahway, N.J., U.S.A.) 24 hr. later half the gibberellin-treated and half the remaining plants were treated with 0·5 ml. 10^{-2} *M* solution of zinc sulphate. Thus four treatments were obtained: 0, control; 0 + Zn, 10^{-2} *M* zinc sulphate; G, gibberellin solution; G + Zn, gibberellin plus zinc solution.

The elongation of the second internode, that is, that between the first and second trifoliate leaves, was measured one week after the application of the gibberellin. A further measurement was taken three days later.

There was a significant difference between the gibberellin treatment and controls, as would be

Table 1. THE EFFECT OF ZINC ON THE RESPONSE OF DWARF BEAN PLANTS TO GIBBERELLIN

Treatment	Stem elongation (mm.) recorded after treatment 7 days	10 days
0	3·8	5·9
0 + Zn	4·8	8·1
G	15·2	52·8
G + Zn	20·8	70·6
Difference required for significance		
P (0·05)	4·1	10·1
P (0·01)	5·6	13·7

expected, but there was also a significant effect ($P = 0 \cdot 01$) between those treated with gibberellin and gibberellin plus zinc solution, the addition of zinc sulphate solution to plants already treated with gibberellin increasing the growth response. Solutions of sulphates of iron, manganese and potassium have not given similar increases in response and one (copper sulphate) reduced growth significantly. It is therefore assumed that the zinc ion was responsible for the effect reported here.

There was a slight, although not statistically significant, increase in the internode-length of plants treated with zinc alone, which may possibly have been due to the effect of the ion on the naturally occurring gibberellin-like substances in the plant.

This work was a continuation of studies started in the Department of Vegetable Crops, Cornell University. The gift of 'Gibrel' from Dr. J. Merritt of the Merck Chemical Co. is acknowledged.

MICROBIOLOGY

Endogenous Metabolism of Freshly Harvested Cells of a Brewer's Yeast

WASHED cell suspensions of yeast have been reported as being able to respire their carbohydrate reserves but unable to ferment these reserves even when the cells were freshly harvested[1,2]. Other workers have reported that an alcoholic fermentation of these reserves is induced in the presence of dinitrophenol, azide and arsenite[3,4]. In the present work it has been found that in a brewer's yeast (*Saccharomyces cerevisiae*) the carbohydrate reserves are degraded by a fermentation process under both aerobic and anaerobic conditions. As a result of this fermentation the total carbohydrate content of the yeast in a suspension at 28° C. decreased by as much as 50 per cent in the 5 hr. following harvesting. The decrease in the trehalose and glycogen fractions accounted for all the loss of carbohydrate.

The yeast was grown up in the medium described by Spiegelman and Nozawa[2]. The incubation temperature was 25° C. The cultures were harvested after 48 hr., washed three times by suspension and centrifugation in $M/15$ potassium dihydrogen phosphate (pH 4·5) and then suspended in the same solution. Manometric measurements of respiration and fermentation were by the direct Warburg method at 28° C. The first manometric readings were always taken less than an hour after harvesting. Yeast carbohydrate was fractionated by the scheme described by Trevelyan and Harrison[5] and measured by an anthrone procedure. Ethanol in the suspending medium was distilled off and determined with liver alcohol dehydrogenase. Dry weights were determined after 48 hr. at 100° C. At the end of each experiment the yeast suspension was examined by the methylene blue technique. The number of cells taking up the dye was always negligible and there was never any evidence of autolysis. No bacterial contamination was ever observed.

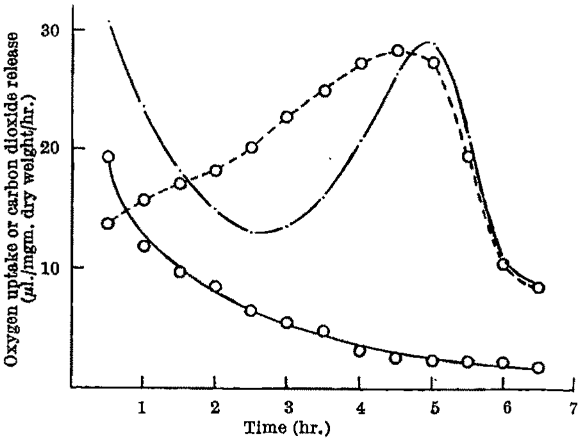

Fig. 1. Each Warburg flask contained 5·8 mgm. (initial dry-weight) of yeast in 3 ml. of *M*/15 potassium dihydrogen phosphate. $Q_{CO_2}(N_2)$, O——O ; Q_{O_2}, O- - - O ; Q_{CO_2}, ·——·

In a series of experiments under anaerobic conditions the decrease in carbohydrate was 85–100 per cent of the amount calculated from the carbon dioxide released (assuming that each glucose molecule in the reserve carbohydrate produces two molecules of carbon dioxide and two molecules of ethanol during the fermentation). The ethanol which accumulated under anaerobic conditions was about 70 per cent of the amount expected from the carbon dioxide released. The $Q_{CO_2}(N_2)$ (µl. of carbon dioxide released per mgm. initial dry-weight of yeast per hour) had an initial value of 16–20 and decreased with time (Fig. 1). In other experiments where the release of carbon dioxide was followed for 9 hr. the $Q_{CO_2}(N_2)$ at the end of this period was still measurable.

Under aerobic conditions the endogenous fermentation was made apparent by a high initial respiratory quotient (1·9–2·5) and the production of ethanol. The ethanol accumulated for 2 hr. and then disappeared from the suspension. The time course of the endogenous metabolism is shown in Fig. 1. Q_{O_2} (µl. of oxygen taken up per mgm. initial dry-weight of yeast per hour) in these experiments had an initial value of 12–14 and then increased to about 28 in about 4½ hr. before falling steeply. Q_{CO_2} had an initial value of 28–32, which decreased for about 2½ hr. before increasing again to the same level as Q_{O_2}.

The apparent respiratory quotient falls rapidly from its high initial value to about 0·6 after about

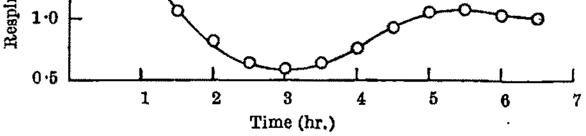

Fig. 2. Apparent respiratory quotient

3 hr. before increasing again to a constant value of about 1·03 (Fig. 2).

Most of the work carried out on the endogenous metabolism of yeast has been on cell suspensions[1–4], but in 1901 Harden and Rowland[6] described an endogenous fermentation in pressed brewer's yeast, resulting in the production of about equimolecular amounts of alcohol and carbon dioxide. These results with pressed yeast have been questioned[1,2,7] because of the possibility that the cells might have been damaged mechanically during the pressing process. The present work with cell suspensions shows that the brewer's yeast used in these experiments does degrade its reserve carbohydrate by a fermentation process, and at the same time the rate of respiration of the yeast doubles.

It is hoped to publish these results in greater detail elsewhere.

I wish to thank the directors of Arthur Guinness Son and Co. (Park Royal), Ltd., for permission to publish this work.

Allyl Alcohol as a Nutrient for Micro-organisms

ALLYL alcohol has in recent years come into some use as a herbicide active against dormant seed. Experiments in progress in this Laboratory have shown that this compound is rapidly detoxicated by biological agencies when added to soil at the rate of 0·02–0·05 per cent; various bacteria capable of utilizing it for growth were isolated from enrichment cultures by plating on selective agar medium. (A few earlier investigators[1,2] have tested allyl alcohol with negative results as a carbon source for fungi and bacteria.)

The active bacteria were partly varieties probably of *Pseudomonas fluorescens* and *P. putida* and partly strains of *Nocardia corallina*. Their growth was tested in soil extract medium containing 0·5 per cent (vol.) allyl alcohol, 0·05 per cent ammonium sulphate, 0·05 per cent dipotassium phosphate and 0·02 per cent magnesium sulphate. Duplicate cultures were grown for one week on a rotating shaker at 25° C., the cells were collected by centrifugation and the amount of growth was measured by determination of nitrogen in the washed-cell deposit. Some representative results are shown in Table 1.

Table 1

Organisms	Cell nitrogen (mgm.) from 100 ml. medium		
		+ Allyl alcohol	Control
Pseudomonas spp. (7 strains)	Min.	2·2	0·2
	Max.	6·8	0·5
	Mean	5·0	0·4
Nocardia corallina (3 strains)	Min.	3·2	0·3
	Max.	4·8	0·5
	Mean	4·1	0·4

Only 2 among 22 strains of *Pseudomonas* spp. isolated by non-selective methods were able to utilize allyl alcohol. Several bacteria belonging to other genera were tested qualitatively with negative results. All bacteria that grew with allyl alcohol could also utilize propanol and sodium propionate, but the reverse did not apply. Among 40 strains of *Azotobacter* and *Beijerinckia* spp. two strains of *A. vinelandii* and one of *A. insigne* utilized allyl alcohol for nitrogen fixation; some 14–20 mgm. nitrogen were fixed per gm. of allyl alcohol supplied.

Also several strains of the fungus *Trichoderma viride* were able to use allyl alcohol for growth. Table 2 shows results found with seven strains grown for 20 days at 25° C. as stationary cultures in soil extract medium with 0·5 per cent (vol.) allyl alcohol. Four of these strains were isolated from selective medium and the rest non-selectively; the two groups of strains showed no essential difference.

Table 2

Dry weight of mycelium, mgm. per 100 ml. medium		
	+ Allyl alcohol	Control
Min.	14	1
Max.	169	5
Mean	90	3

A number of other fungi, collection cultures as well as random isolates from soil, were tested qualitatively with negative results; among these were also some strains of *Trichoderma viride*.

Experiments on the rate and mechanism of biological detoxication of allyl alcohol are in progress; the results will be published elsewhere.

I am indebted to Dr. Hans Lautrop, Statens Seruminstitut, Copenhagen, for supplying me with a number of strains of *Pseudomonas* spp.

Mode of Division of Pediococci

THE differentiation of pediococci from other groups of spherical lactic acid bacteria has frequently been based on the characteristic morphological arrangement into tetrads[1–3]. It has been generally assumed that the occurrence of tetrads is attributable to division in two planes[1,3]. However, some workers[4,5] have expressed the view that pediococci divide in one plane only, giving rise to chains similar to those formed by streptococci, and that tetrad formation is due to re-arrangement of 3–4 membered chains.

In all these investigations the mode of division has been deduced from examination of stained preparations only. It was decided, therefore, to follow the sequence of division of several strains, starting from single cells, by direct microscopic observation of developing slide cultures under a phase-contrast microscope. The cultures were made on semi-solid

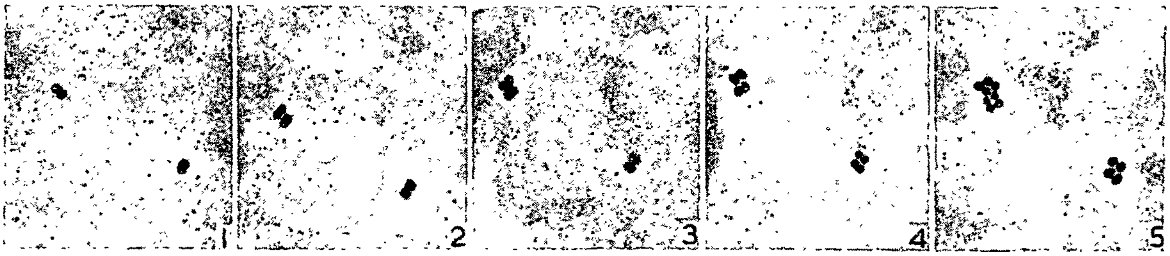

Fig. 1. Photomicrographs of division of *Pediococcus cerevisiae* strain 8081. Incubation for: (1), 0 hr.; (2), 1 hr. 45 min.; (3), 2 hr. 20 min.; (4), 3 hr. 20 min.; (5), 6 hr. 15 min. (× *c.* 710)

agar (tomato or glucose-yeast broth, *p*H 6·8 with 0·5 per cent Davis agar) and the microscope was fitted with a Newman Waterfield warm stage adjusted to 30° C. Series of photomicrographs were taken during the course of these observations, and one such series, which is representative of the sequence of divisions shown by all strains of pediococci studied, is reproduced in Fig. 1. The photomicrographs demonstrate clearly that division of pediococci occurs in two planes, and that successive divisions are approximately at right angles to each other.

Representatives of the streptococci, micrococci and sarcinae, studied under identical conditions, exhibited the typical modes of division associated with their respective groups.

The results of these experiments indicate clearly that the mode of division of the pediococci differs from that of the streptococci. In addition to their physiological differences, the two groups of organisms may be distinguished, therefore, on the basis of their morphology.

This work was undertaken during the tenure of a postgraduate scholarship awarded by Queen Elizabeth College (University of London).

A Gram-negative Sporing Bacterium from the Rumen

REPORTS in the literature of Gram-negative sporing bacteria are comparatively rare, although recently three have been mentioned[1-3], two from the rumen contents of cattle or sheep. We have obtained some Gram-negative sporing organisms during investigation of rumen bacteria. Three isolations were obtained from Gram-negative rods of the genera *Bacteroides* and *Butyrivibrio*[4] which had been isolated at different times from the rumens of sheep or cattle using a strictly anaerobic technique, based on that of Hungate[5], with either xylose or xylan as carbohydrate. Sporing forms were first noted on reculturing freeze-dried cultures. It seemed unlikely that the sporing bacteria were airborne contaminants, and although they were, under some conditions, very similar in morphology to the *Bacteroides* and *Butyrivibrio* spp. their properties always differed from these bacteria even after continued anaerobic culturing.

Two pure cultures of the sporing organism were obtained from the mixed cultures by micro-manipulation and culture of single spores, and a third by heat treatment of a sporing culture. A fourth isolation was made from the rumen contents of a sheep (not the one from which the original cultures were obtained). Although occasional sporing organisms of this type were seen in cultures made from dilutions of rumen fluid under anaerobic conditions it did not prove possible to isolate them anaerobically or by anaerobic followed by aerobic culture, so it was decided to use an aerobic technique, with xylose as carbohydrate, as this would destroy the similar Gram-negative non-sporing rods. To prevent overgrowth by other facultatively anaerobic organisms common to the rumen contents, penicillin (10 units/ml.) was incorporated in the diluting fluid and culture medium. Growth was obtained only to a dilution of rumen contents of 10^{-2}, and an isolation was made from the first dilution. All four isolations were similar straight or slightly curved rods (1·8–3μ × 0·8μ, but longer forms were seen), Gram-negative when stained in conjunction with known Gram-positive and -negative organisms, and having subterminal oval spores. Very occasional Gram-positive forms were also seen. Occasional motile cells were found, with a terminal flagellum. All grew aerobically or anaerobically, but better growth, and a lower *p*H in sugar media, were usually obtained aerobically. The spores of one isolation survived heating in physiological saline suspension in a boiling water-bath for 20 min., but were killed after 40 min.

Sugar fermentations were tested in a medium containing yeast extract and mineral salts incubated under carbon dioxide or aerobically. The fall in *p*H resulting from growth in sugar-containing media was not usually very great, and all reactions were checked with a Pye *p*H meter, a fall from 6·9 to 5·9 being considered positive. Xylose, glucose, fructose, mannose, galactose, lactose, cellobiose, melibiose, xylan, dextrin and amylopectin were fermented by all isolations with no visible gas formation. The fermentations of arabinose, maltose, trehalose, raffinose, glycogen, mannitol and α-methyl glucose were variable or indefinite. Rhamnose, fucose, inulin, salicin, æsculin, sorbitol, dulcitol, adonitol, glycerol, sodium succinate, lactate, malate, fumarate and citrate, were not fermented. Nitrate reduction, methyl red reaction and catalase production were positive. Voges-Proskauer and indole reactions, ammonia and hydrogen sulphide production, and urea and gelatin hydrolysis were negative. No growth was obtained in Koser's citrate medium, and the final *p*H in glucose–peptone broth was 5·2–5·6. Litmus milk was decolorized but no clot formed. The products of fermentation of xylose, chosen to compare these bacteria with the *Bacteroides* and *Butyrivibrio* spp., were formic, acetic and lactic acids in the equivalent proportions 19 : 17 : 1. Succinic acid was not determined.

Antisera were prepared by inoculation of formolized suspensions into rabbits. Cross-agglutinations were found between the culture isolated directly from the rumen and the isolate from the culture of a sheep rumen bacterium. The two isolations from cultures of cattle rumen bacteria appeared to be serologically different from those of sheep. The one isolate tested was also different from the culture of *Bacteroides* sp. from which it was originally isolated.

In biochemical properties the bacteria resemble *Bacillus circulans*, but no motile colonies have been noted, although the growth was very thin and spreading on plates. It is not known whether the organisms play any part in rumen metabolism, although they must at times be present in fairly high numbers to have been isolated along with the cultures of *Bacteroides* and *Butyrivibrio* since these were taken from quite high dilutions of rumen contents. Appleby[6] isolated from the sheep rumen along with other proteolytic bacilli one culture, identified as *Bacillus circulans*, which liquefied gelatin. The Gram-negative sporing bacterium isolated by Gray[2] from the sheep rumen is said to resemble *Clostridium kluyverii* in properties. The present bacteria are somewhat similar in morphology to organisms described by Gutierrez[3], which were ingested by the rumen protozoan *Isotricha prostoma*, and possibly served as a nitrogen source for this protozoan.

We would like to thank Dr. K. I. Johnstone of the University of Leeds for obtaining one single-spore culture and for instruction in his micromanipulation technique to one of us (M. R. P.), Miss M. Garvock for the acid analyses, and Mr. S. O. Mann for discussion.

GENETICS

A New Physical Method of creating Chromosomal Aberrations

Recent observations in this laboratory[1,2] have indicated a wide and unusual spectrum of effects which can be obtained from a radio-frequency source in the megacycle range. In order to minimize dielectric heating, it was necessary to reduce the mean power input and therefore we have used a pulsed radio-frequency source at 27 Mc./s. The pulses are of the order of 5×10^{-5} sec. Most of the effects described herein are produced with between 80 and 180 pulses per sec.

For microscopical and genetic studies we used two electrodes separated by an air gap of 3–15 mm. The electrodes were coupled to the primary radio-frequency source. There is a peak-to-peak voltage of about 1,000–1,500 V. The microscopic and genetic preparations were insulated from the electrodes by two layers of glass. It can be observed that a large variety of substances, including iron, carbon, silver, oil, fat droplets, starch grains and mammalian cells, will react to this field in two ways. First, any asymmetrical particle will be oriented with its long axis along the lines of force. Secondly, after orientation (which, of course, is not observed in symmetrical particles such as spheres) these particles will form chains along the lines of force as though they were iron filings between two poles of a magnet.

One of the most dramatic demonstrations of this effect can be seen when motile bacteria or protozoa are in this field. When the field is impressed, the micro-organisms can migrate only along the lines of force. As soon as the field is turned off, they resume their random movement. This can be repeated as many times as desired.

The thermal component is obviously sufficiently low so as not to affect the viability of these organisms or mammalian cells. In a larger, immobilized

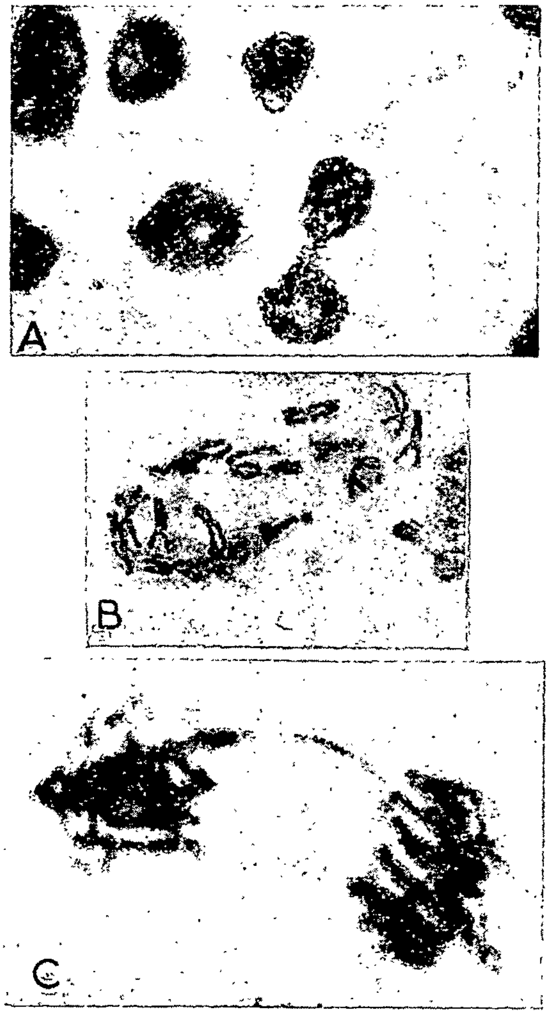

Fig. 1. Squash preparation of garlic root-tips 24 hr. after 5 min. of exposure in the electromagnetic field. *A*, Resting stage of an irradiated cell showing two nuclei linked by a chromatic bridge and no cytodieresis; *B*, metaphase with linear shortening of chromosomes; *C*, bridging

micro-organism we were able to observe intracellular orientation of subcellular particles. This led us to believe that this force might be used as a powerful and controlled mutagenic agent. Growing garlic root-tips in water were placed in a field between two insulated electrodes. No temperature increase in the water was noted. The tips were exposed for a 5-min. period and examined 24 hr. later.

Among those aberrations seen were linear shortening of chromosomes, pseudochiasmata, amitotic division, bridging, irregularities in the chromosomal envelope. The effects noted mimicked those produced by ionizing radiation and *c*-mitotic substances.

Fig. 1 shows some of the chromosomal aberrations observed. It is believed that this represents a new tool which may induce chromosomal aberrations to a degree contingent upon frequency, pulse, power, exposure time, and the axis of the cell *vis-à-vis* the field. Further experiments on the physical basis of these changes, as well as chromosome and mutation studies on other materials, are at present under investigation.

Preliminary Information on the Genetics of Ethiopian Coffees

LITTLE is known about the genetic variability of the species *Coffea arabica* in its native home—south-west Ethiopia. Recently, however, seed samples of wild, cultivated and subspontaneous coffees in this region have been gathered by various agriculturists[1,2]. Several small seedling populations from Ethiopia were sent here in 1952 and 1953, and the genetic constitution of some of them is now being worked out.

It was noted that the 'Erithrean moca' coffee (*PI* 205 413, U.S. Dept. Agric.) is identical with the *semperflorens* mutant, being homozygous for the alleles *sfsf*[1].

The results of artificial pollination with the *murta* variety (*ttNana*) revealed that from 33 analysed coffee plants from Ethiopia, 23 carry the alleles *tt*, probably in the homozygous condition. The alleles *tt* characterize the variety *bourbon*, and its presence in Ethiopia indicates that this region and not Reunion Island, as formerly thought, is the place of origin of this important commercial variety. The *typica* variety (*TTNaNa*) also occurs in Ethiopia.

Plants of the *abyssinica* variety were frequently found in some of the seedling populations. Although the alleles responsible for its main characters are not yet known, it was noted that *abyssinica* plants carry the alleles *TT*. Other populations segregating for *abyssinica* characteristics bear the alleles *tt*. The coffee type *Ennarea* or *Ennaria*[1] does not seem to belong to this variety.

The genetic analysis of the colour of the young leaves revealed that the allele *br* is frequently found in the imported plants. A new recessive allele, *semierecta* (*se*) with a phenotypic effect somewhat similar to the dominant allele *erecta* (*Er*), was observed[3]. Plants with large fruits and seeds, *macrocarpa*, were noted but no information is available with regard to their genetic constitution.

Coffee seedlings with a small foliaceous and persistent calyx were found in the populations of plants identified as *S.4-Agaro* (*PI* 205 408) and *S.6-Cioccie* (*PI* 205 411) coffee. In spite of having developed sepals, these plants do not carry the allele *sd*[4]. An interaction, however, seems to occur between the *sd* and the allele or alleles responsible for persistent sepals from Ethiopia.

Other variations concerning: leaf shape; their position on the lateral branches; fruit shape; colour of the berry; period of fruit ripening and vegetative vigour, were also found.

This rather intensive variability encountered in the seedlings received from Ethiopia may be the result of a non-randomized procedure of seed collection, seeds very often having intentionally been harvested from more or less conspicuous variants, occurring in the Ethiopian coffee forests. Possibly a higher amount of natural cross-pollination, occurring in the native habitat of *C. arabica*, may also be responsible for this marked genetic heterogeneity.

The occurrence of several new genetic factors in such a small sample of Ethiopian coffee indicates that further exploration for coffee mutants in Brazil is highly desirable, to throw more light on the genetics of *Coffea arabica* and also to provide more basic material for its improvement.

Acknowledgment is due to Dr. C. A. Krug for help in the preparation of this communication.

BIOLOGY

Generic Nomenclature of the Intermediate Hosts of *Schistosoma mansoni*

IT has been shown by Hubendick[1] that the molluscan intermediate hosts of *Schistosoma mansoni* in Africa and South America are congeneric. The selection of the correct name for this genus of planorbid snails cannot be decided by a simple application of the rule of priority, because there is a conflict of opinion as to which is the oldest available name. The situation is further complicated by the fact that the names competing for precedence under the rule of priority are all quite unknown to the medical field workers and parasitologists who are frequently concerned in studies on these snails. An application has therefore been made to the International Commission on Zoological Nomenclature by Drs. F. S. Barbosa, B. Hubendick, E. A. Malek and myself asking for a decision which will stabilize the nomenclature of this economically most important group. It is probable that the decision of the Commission will not be made known for some time. It is for this reason that I am anxious to direct the attention of workers who may be concerned with these snails to the normal practice of adhering to existing nomenclature while an application is before the Commission. Thus, until a decision has been given, the generic name used for the African intermediate hosts of *Schistosoma mansoni* should be *Biomphalaria* and for the South American hosts either *Australorbis* or *Tropicorbis*.

Effect of Gamma-Radiation on Weeds

Considerable data are now available on the radiosensitivity of cultivated plants[1,2], but very little is known about the tolerance of wild species. We have investigated the doses of γ-radiation needed to prevent weed seeds from growing. The seeds were stored at 32 per cent relative humidity and irradiated in air with a range of doses from 0 to 100,000 rads of γ-radiation from cobalt-60. They were then planted in steam-sterilized soil and the number of plants arriving at maturity were counted. *LD*50 values for some common species of arable weeds are listed in Table 1.

Table 1. *LD*50 Doses for Arable Weeds

Species	Chromosome number (ref. 3)	Approximate *LD*50 (rads)
Plantago major	12	10,000
Anisantha sterilis	14	5,000
Alopecurus agrestis	14	20,000
Papaver rhoeas	14	30,000
Medicago lupulina	16 or 32	80,000
Brassica nigra	16	100,000
Atriplex patula	18	10,000
Anthemis arvensis	18	20,000
Raphanus raphanistrum	18	20,000
Sinapis arvensis	18	100,000
Veronica persica	28	>100,000
Galeopsis tetrahit	32	10,000
Sonchus oleraceus	32	10,000
Capsella bursa-pastoris	32	100,000
Polyganum convolvulus	40	30,000
Senecio vulgaris	40	80,000
Rumex obtusifolius	40	100,000
Avena fatua	42	20,000
Avena ludoviciana	42	20,000
Euphorbia helioscopia	42	20,000
Papaver dubium	42	30,000
Stellaria media	42	60,000
Galium aparine	44, 66 or 88	80,000
Cerastium vulgatum	144	80,000

Fig. 1 shows the effects of radiation on *Alopecurus agrestis* planted at a rate of 50 seeds per box. Several characteristic radiation effects were observed. Germination was not related to survival, as irradiated seedlings were generally weaker than controls, and often had distorted first leaves. Seedlings which survived matured later than controls but were not obviously distinguishable otherwise : induced sterility was frequently noted. The *LD*50 doses could not be correlated with any simple character such as chromosome number, though all plants with high chromosome numbers were always radioresistant. The species studied fall into two groups, those with *LD*50 doses less than 30,000 rads and those with *LD*50 doses, greater than 60,000 rads. Apart from *Raphanus* all the crucifers examined come in the second group and the four grasses in the first. *Anisantha sterilis* is remarkably radiosensitive, whereas *Veronica persica* must be one of the most radioresistant plants known.

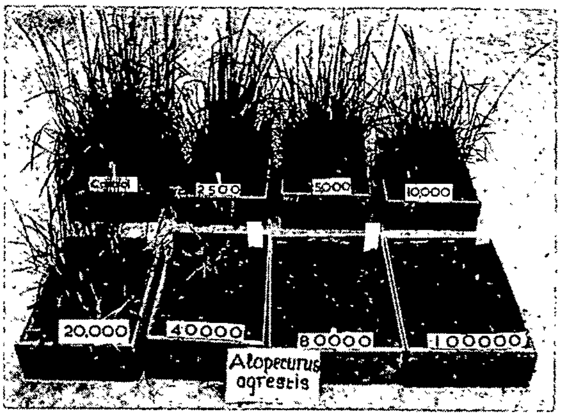

Fig. 1

The results obtained indicate that arable soils need treatment with at least 100,000 rads of γ-radiation to inhibit weed growth effectively. This treatment would sterilize any insects[4], or nematodes[5] present in the soil, and would probably destroy a high percentage of the bacteria[6,7] and fungi[7,8].

We wish to thank Mr. I. M. Rorison for supplying the seeds of *Papaver rhoeas* used in this work.

Seasonal Changes in the Brain-case of the Common Shrew (*Sorex araneus* L.)

It is well known that shrews of the genus *Sorex* undergo a striking seasonal fluctuation in average weight and length of body[1]. This is mainly brought about by the annual turnover of the population and the rapid spring growth associated with sexual maturation. An additional contributory factor is the decrease in weight of the sub-adults as the winter of their year of birth approaches. This has been detected in large field samples of *S. araneus*[2,3], *S. fumeus*[4] and *S. vagrans*[5].

It was completely unsuspected, until discovered by Dehnel[3], that the autumnal depression in size of body was accompanied by a shrinkage in the size of the skull, the most striking change occurring in depth of the brain-case. Cabon[6] found a similar seasonal fluctuation in brain-case depth in *S. minutus*, and established that this was associated with changes in brain volume. The same seasonal change has been demonstrated in Polish *Neomys fodiens*[7], and in a collection of north German *S. araneus* in the Berlin Museum[8].

We were not completely satisfied that differences in depth of brain-case, of the order shown by Dehnel and his associates, could not be due to chance and the inevitable errors incurred with calipers, particularly as the samples for the crucial months were small.

The difficulties of attaining consistent accuracy when measuring small skulls with hand-operated calipers are notorious, as are the difficulties of introducing mechanical aids. Micrometers for use in engineering are commonly fitted with a means of applying a standard pressure between the jaws, but none suitable for measuring a small fragile object such as the skull of a shrew could be found. Mr. G. H. C. Jones, of the Science Museum, London, designed and made a measuring instrument specially for this purpose. This consisted of a lever pivoted near one end and counterpoised by means of a plunger within a solenoid. By operating a rheostat, a stylet attached to the short end could be brought to bear with constant pressure upon skulls resting on a metal plate. The measurement could then be read directly from a scale behind the other end of the lever. In order to measure depth of the brain-case, each skull was placed upside down upon the plate, the nasals resting on a wedge of 'Plasticine' to bring the floor of the brain-case to the horizontal. The stylet was then applied to the centre line of the basisphenoid. This gave the distance from the ventral surface of the basisphenoid to the highest point on the dorsal surface of the parietals. These measurements are smaller than those given by Dehnel[3] for brain-case depth in the same species, as his measurements were taken from the bullæ.

The depths of the brain-cases of 423 *Sorex araneus* from Wytham Estate, Berkshire, were measured in this way. The animals were taken in all seasons during October 1949–November 1951, and their reproductive condition and approximate ages were known. Thus it was possible to separate adults from young of the year, and to plot the changes in brain-case depth occurring within one generation of shrews. In Fig. 1 the means of depths of brain-cases in monthly samples of shrews born in 1949 are shown, together with the 95 per cent confidence limits of the means. It is clear that mean depth of brain-case decreases significantly between October and January, increasing thereafter until July, and then decreasing again as the end of the life-span approaches. The figures for the shrews born in 1950 show a similar trend although the samples are too small to be treated statistically.

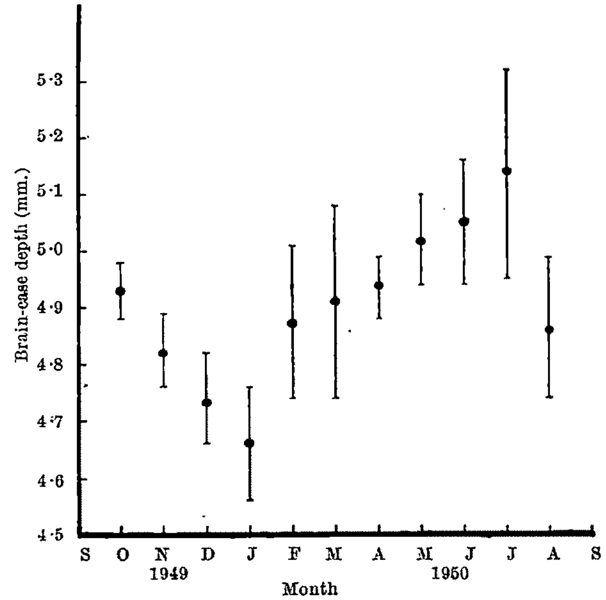

Fig. 1. Monthly means of depth of brain-case in *Sorex araneus*. Vertical lines show 95 per cent confidence limits

The hypothesis that the decrease in mean depth of brain-case is not due to shrinkage but to dilution of the population with small individuals from later litters cannot be supported, for the bulk of the annual 'crop' of common shrews is produced in June and July, very few females becoming pregnant as late as September. Furthermore, no breeding has ever been found to occur in *S. araneus* as late as December and January.

Thus Dehnel's "concertina" effect has been demonstrated in yet another population of common shrews and in a country with a much milder winter than that of eastern Europe. The more severe climatic changes suffered by the Continental shrews may account for their greater seasonal variation in brain-case depth. Similar studies of shrews from various regions of North America would be of great interest. Clothier[9] reported some variation in skull height in *Sorex vagrans* from Montana (U.S.A.), but it was not statistically significant. Similar studies of samples of this species from the extremes of its range may provide a means of assessing the effect of climate on seasonal skull variation.

In addition to recording our gratitude to the Director of the Science Museum, and to Mr. G. H. C. Jones, we wish to thank Mr. M. D. Mountford, of the Nature Conservancy, for carrying out the statistical analysis.

Entry of Spermatozoa into the Fallopian-Tube Mucosa

It was reported recently that spermatozoon heads had been observed in the mucous membrane in histological sections of the Fallopian tube of two greater horseshoe bats (*Rhinolophus ferrum-equinum*) and four common pipistrelles (*Pipistrellus pipistrellus*)[1]; spermatozoa were not found in the uterine tissues. Similar observations have since been made in two rats, one rabbit, one hedgehog (*Erinaceus europaeus*), one mole (*Talpa europaea*) and two stoats (*Mustela erminea*). Spermatozoa considered to be in the mucosa were all in the thickness of the section and not on the surface. They were found even in individuals in which the lumina of tube and uterus contained few if any spermatozoa. When spermatozoon heads lay close to mucosal-cell nuclei, there was generally evidence of a local reaction, namely, a flattening or indentation of the opposed surface of the nucleus. Spermatozoa were not seen in sub-mucous tubal tissues. It is concluded, therefore, that the phenomenon is real, and not attributable to artefact, and that it is probably general.

In some respects, these observations resemble those of Kohlbrugge[2], who claimed to have identified spermatozoa within the uterine mucosa in elasmobranch fish (*Scyllium* and *Torpedo*), the domestic fowl, bats of two species (*Xentharpya amplexicaudata* and *Pterogistes stenopterus*) and the rabbit, and also within the Fallopian-tube mucosa in the mouse. Spermatozoa were said to pass into the sub-mucous connective tissue of the uterine wall in *Xentharpya*. Kohlbrugge maintained that the invading spermatozoa exerted upon the uterus a trophic influence that not only played a part in the ensuing pregnancy, but also persisted and constituted part of the mechanism of telegony. Kohlbrugge's work and ideas have received support especially from Russian investigators[3]. However, serious doubts concerning the validity of conclusions drawn from histological studies have been raised by Vojtiskova[4]. She considers that previous reports, including her own earlier paper, were misleading because what the authors had interpreted as spermatozoa which had penetrated uterine tissues *ante mortem* were in reality luminal spermatozoa displaced during the preparation and cutting of the tissue and transferred to other parts of the sections. Consistently with this view, Austin[5], Pósalaky and Törő[6], and Edwards and Sirlin[7] announced that they could find no evidence that spermatozoa entered uterine tissues in the rat and mouse.

There is little doubt that, in the past, workers may often have been misled by artefacts in their material; but the new findings here described show that it would be rash to discount all previous reports on these grounds. Since incorporation of spermatozoa into the female tissues could have far-reaching immunological and genetic consequences, a re-investigation of the claims of Kohlbrugge and others is well justified.

I am greatly indebted to Dr. Ruth Deanesly for the opportunity of examining her histological preparations of material from *Pipistrellus*, *Erinaceus*, *Talpa* and *Mustela*, and to Mr. Michael Blackmore for collecting the specimens of *Rhinolophus*.

An Abnormality in the Skin of Sheep

THE normal procedure for fellmongering (removing the wool) English skeep skins is to paint the inner surface of the flayed skin with a paste of sodium sulphide solution thickened with lime. After allowing time for the chemicals to penetrate the dermis and dissolve the roots of the wool, the wool is pulled. The epidermis is also removed and the pelt is left in a semi-swollen condition. The pelt then goes forward to the subsequent processes of leather manufacture.

In the course of work on a new method of fellmongering involving treatment with proteolytic enzymes in place of sulphide and lime, the pelt, which is completely flaccid and unswollen when the wool is pulled, frequently showed a blistered effect on the grain (the epidermis – dermis junction forms the grain surface of the leather). The blisters appeared like small air bubbles up to about 3 mm. in diameter trapped under the grain, and they could be pushed around with the finger. They occurred only on fine-woolled skins and always in the areas around the hind shanks, occasionally extending a considerable distance towards the neck (Fig. 1). Lamb skins were affected more than sheep skins: in some packs of lamb skins as many as 40 per cent were affected. The phenomenon was independent of the temperature of treatment of the skins over the range 21–32° C.

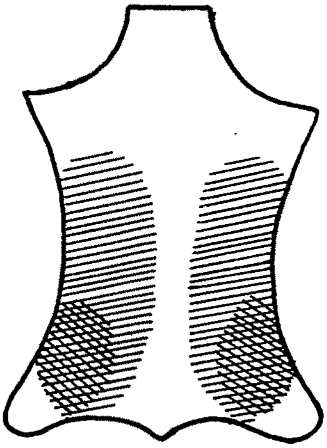

Fig. 1. Diagram of sheep skin showing areas susceptible to blistering. The cross-hatched areas are those which most frequently show the defect, but it occasionally extends over the line-shaded areas

The blisters were found microscopically (paraffin and frozen sections stained with azure *A*) to be associated with cavities occurring at all levels in the dermis. They were already present in the untreated skin and hence were not a condition induced by processing. Fig. 2 shows them in the papillary layer between the wool follicles of the untreated skin, and Fig. 3 in the dermis of the same section near the inner limiting layer. The wall of the cavity seems to be formed by the rearrangement, but not thickening, of ordinary fibres of the dermis. No contents such as fat, micro-organisms or infesting parasites have been observed within the cavities.

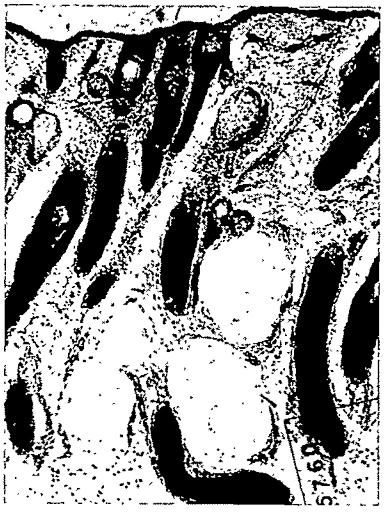

Fig. 2. Papillary layer of blistered sheep skin showing four cavities among the hair follicles (frozen section, azure *A*. × *c*. 57)

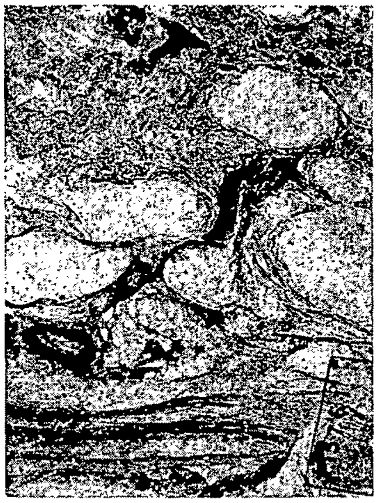

Fig. 3. Dermis of blistered sheep skin, near the inner limiting layer (frozen section, azure *A*. × *c*. 57)

No mention of this phenomenon is made by Seymour-Jones in his authoritative work on sheep skins[1]. Before sulphide and lime came into use, English skins were sweated, a bacterial process related to enzyme dewoolling but subject to much less control, which would leave the pelt in essentially the same flaccid condition as after enzyme treatment. It is possible that the condition was overlooked by Seymour-Jones, since the sweating process had long since been abandoned, or the breeds of sheep that were reared in the days of sweating were not subject to this phenomenon: there has been a progressive change in the types of sheep being bred over the past century. Apart from classifying the type of sheep subject to this blister as fine-woolled, no more exact designation can be given owing to the large amount of cross-breeding that is carried out resulting in the receipt by the fellmonger of miscellaneous types of cross-bred skins. The failure to observe the blisters in recent years is most likely due to the fact that the susceptible area is not often examined by leather microscopists, and to the probable collapse of the cavities during manufacture of the skin into leather.

Note added in proof. Since the above was written, Mr. J. Tate, who has been connected with the fellmongering industry for seventy years, has confirmed that sweated domestic sheep skins were subject to blistering, and the cause was unknown.

Abnormal Resistance of *Poria vaillantii* (D.C. ex Fr.) Cke. Strains to Copper–Chrome–Arsenate Wood Preservatives

CERTAIN species of *Poria* causing brown rot in wood, including *P. vaporaria* (Pers. ex Fr.) Cke., *P. vaillantii* (D.C. ex Fr.) Cke., *P. xantha* (Fr.) Cke., and *P. monticola* Murr., are much more resistant to the toxic effects of simple copper salts than are most wood-destroying fungi, but have been readily inhibited by the copper–chrome–arsenate preservatives which are now in common use[1]. During wood-block tests of wood preservatives in this laboratory, however, one strain of *P. vaillantii* was found to be unaffected by these preservatives at the usual concentrations, and the tolerance of various strains of the species was therefore investigated by testing their ability to decay sawdust treated with increasing concentrations of such preservatives, using a modification of the sawdust dish – soil jar decay resistance test of Da Costa and Rudman[2].

A 4-gm. sample of air-dry sawdust (23–72 mesh) of the sapwood of *Pinus radiata* D. Don was mixed thoroughly with 7·5 ml. of the appropriate preservative solution, packed down tightly, and left 1–3 days to allow the preservative to distribute itself uniformly through the sawdust particles and to react with the wood components. The treated sawdust was then vacuum dried at 40° C. with frequent stirring, and 0·4 gm. samples placed in aluminium foil dishes (1 in. diam.; $\frac{3}{4}$ in. high) with perforated bottoms. The dishes of sawdust were sterilized by fumigation with propylene oxide and placed on pure cultures of the test fungus on thick filter paper disks, soaked in a solution of 2 per cent dextrose, 0·4 per cent casein hydrolysate, 0·4 per cent peptone, 0·05 per cent crystalline magnesium sulphate, 0·15 per cent potassium dihydrogen phosphate, 0·001 per cent thiamine hydrochloride, and resting on moist soil in glass jars. After incubation at 25° C. and 99 per cent relative humidity for 5 weeks, the dishes were vacuum dried and re-weighed and the amount of decay expressed as the percentage loss in oven-dry weight.

Initial tests with a typical proprietary preservative of the copper–chrome–arsenate type (Table 1) showed that the high tolerance previously noted was not shared by species of *Poria* of similar habit, or indeed by all strains of *P. vaillantii*. There were, however, three tolerant strains of very diverse origin, the most tolerant being *DFP*4443, which had been isolated originally from *Pinus radiata* treated with a copper-chromate preservative. This strain was used for making further tests with individual compounds commonly used in highly fixed water-borne inorganic preservatives of the metal–chrome–arsenate type.

Each compound was tested in a wide range of concentrations (for example, crystalline copper sulphate, 0·01, 0·015, 0·02, 0·03, 0·04, 0·06, 0·08, 0·12, 0·16, 0·24, 0·48, 0·64 'molal', where 1 'molal' has 1 gm. molecular weight added to 1,000 gm. of sawdust), and certain commonly used combinations

* Gm. molecular weights added to 1,000 gm. of oven-dry sawdust.

† Gm. of dry (not anhydrous) salt added to 100 gm. oven-dry sawdust.

‡ Concentration of each component.

§ Total percentage of all components.

were tested as equimolecular mixtures. From the dosage-response relationships obtained, the total inhibition point (that is, the minimum concentration of preservative necessary to reduce the weight loss to zero) was computed for each preservative (Table 2). For any one preservative the amount of decay produced was approximately in inverse proportion to the logarithm of preservative concentration: some preservatives showed significant, though slight, deviations from this relationship, and these have been taken into account in calculating the fiducial limits given.

The resistance of strain *DFP*4443 to copper and zinc is even higher than would be expected from previous reports on the copper-tolerant species of *Poria*, and this strain is also highly tolerant of arsenic. Later tests, in fact, show it to be more tolerant than *Lenzites trabea* (Pers.) Fr., which is widely used as an arsenic-tolerant fungus in testing wood preservatives. It is presumably this high tolerance of arsenic which distinguishes the strains found here to be tolerant of copper–chrome–arsenates from the *Poria* strains used elsewhere in tests of these preservatives.

I wish to acknowledge the assistance of Messrs. L. Bartak and J. M. Stephenson in these investigations, which will be reported more completely at a later date.

Density-Dependent Factors in Ecology

ANDREWARTHA's ideas on density-dependent factors[1] in ecology are very misleading, and have already been criticized by Huffaker[2]. I wish to refer to three points which he raises in his recent communication. First, he argues that since the population models of Lotka and Volterra are based on density-dependent relationships, and these have been "partly confirmed by laboratory experiments with such simple animals as *Paramecium*, but not with more complex ones such as *Calandra* and *Tribolium* and not with any sort of animal in Nature", this is evidence against the applicability of ideas of density dependency. Yet density-dependent relationships are known to operate in two ways in *Tribolium* cultures. Chapman[3] found the beetles ate their own eggs, and Boyce[4] showed female beetles laid fewer eggs when crowded. The Lotka–Volterra formulæ have seldom been applied to interpret these happenings because they are not properly applicable to animals with a long pre-reproductive period. However, Crombie[5] has used the formulæ with encouraging success to interpret the results of competition between the beetles *Oryzaephilus* and *Tribolium* and other grain insects.

Secondly, he quotes Nicholson's formula[6] relating the equilibrium population density N_E of an animal to its food supply g:

$$N_E = \frac{g - lg - wg}{q}$$

where l is the fraction of food lost to extraneous factors and w the fraction wasted by surplus individuals which fail to mature, and q the quantity of food required to complete development. By putting $w = 0$ or 1 Andrewartha claims to 'solve' the equation, whereas he is determining only the limits of possible solutions. Since w is itself a function of the population density N, a solution can be obtained only if the appropriate function of N is substituted for w. If, however, the competitive scramble for food wastes a negligible amount so that $w = 0$, then $N_E = \frac{(g - lg)}{q}$, which has a simple biological meaning. Andrewartha's categorical assertion that "This does not satisfy the concept of an equilibrium density" seems to be a *non sequitur*.

I agree with Andrewartha that the experiment he outlines to test the action of density-dependent factors is unable to prove anything; but far better methods are available. Density-dependent factors can be identified by their observed effects at a variety of population densities, and their ability to reduce high populations either asymptotically or with damped oscillations to the equilibrium density can be checked.

For the idea of density-dependency to be useful, the idea must be properly understood. If factors are to be invoked to explain population stability, they must have certain well-defined properties[7]. To use the term inappropriately and in senses entirely different from the original definition causes nothing but confusion.

ANDREWARTHA[1] has criticized an equation which he wrongly designates my "equation for intraspecific competition". Actually, it simply represents symbolically the necessary conditions for equilibrium in a postulated simple situation, other equations being given for other simple situations. His conclusion that "the equation is a tautology" is wholly due to his unjustifiable assumption that this equation is intended to represent the operation of competition.

The same assumption underlies his conclusion that the equation "does not satisfy the concept of an equilibrium density", arguing that "solving the equation for values of w between 1 and 0 gives values of N_E between 0 and $\frac{g - lg}{q}$". (w is the fraction of the governing requisite wasted by the animals which scramble for it, N_E the equilibrium density of the population, g the rate of generation of the governing requisite, l the fraction of this lost to the animals due to other agencies, and q the amount of the requisite required by an animal for development to maturity). The implication is that w, and therefore N_E, are indeterminate. However, as with the other parameters in the equation, the equilibrium value of w is determined by properties of the animals and those of the environment, and not by the equation. Andrewartha appears to have overlooked the statement[2], which immediately precedes the equation, that the "surplus individuals waste a fraction (w) of the governing requisite, in the sense that this fraction is rendered unavailable to those individuals which maintain the population by maturing and reproducing". Thus at equilibrium the value of w is positively related to the fraction of offspring which is surplus, and is influenced by the relation existing between crowding and the wastage (wg) of the governing requisite.

The equation under discussion is $N_E = \frac{g - lg - wg}{q}$, which does not purport to indicate how competition can bring about equilibrium. This question is discussed verbally and mathematically in neighbouring parts of the same article[2], but Andrewartha makes no reference to this discussion. It can readily be outlined by reference to the equation. Keeping in mind the fact that the fraction (w') of the governing requisite, say, food, which is wasted by the scrambling animals is positively related to the population density (N) at any given time, it is easy to see that when $N < N_E$ the wastage of food at that time is relatively low, that is, $w' < w$. More of the food is therefore available for the development of mature animals, and so $N \rightarrow N_E$, as similar arguments show it does when $N > N_E$. Thus competition among the animals sets up reactions which always tend to cause an approach to the equilibrium density. However, as the development of animals takes time, there tends to be an alternate over-shooting and under-shooting of the equilibrium density, for there is a delay in the operation of the corrective reaction induced at any given density.

Having determined the diminution of egg production by adults, and the increase of larval mortality, due to the wastage of food caused by different degrees of crowding in cultures of *Lucilia cuprina*, I was able to deduce the very varied patterns of population-growth and maintenance and the greatly differing levels populations would maintain, or oscillate about, under different specified conditions. These deductions were tested experimentally by subjecting populations of this blowfly to the postulated conditions, and the results obtained always agreed closely with expectation. Some of these experiments have already been described[2,3]. They all clearly demonstrated the governing function of density-induced reaction, which was the primary hypothesis underlying my predictions. Many other investigators have also successfully used the underlying idea of 'density-dependent factors' to assist them in their experiments and observations. Andrewartha's claim that this idea has been unfruitful is untenable.

At no time have I argued, as Andrewartha claims, "that only density-dependent factors can keep a population from becoming extinct", except in the special sense that such factors alone can prevent populations in favourable situations from becoming so large that they endanger their own existence. The views I have expressed[4] are that animals are necessarily excluded from all inherently unfavourable regions; that within favourable regions they characteristically multiply when unchecked; and that growth to indefinitely large numbers is prevented by density-induced opposition, such as the depletion of requisites, which automatically adjusts populations at, or fluctuating about, levels related to the properties of the animals and those of their environments. There is no need to attempt the impossible task of proving a null hypothesis by an experiment of the kind Andrewartha mentions. The views I have just expressed form a positive hypothesis which not only can be, but already has been, tested and confirmed by many experiments, as I have just indicated.

Fossil Reptiles from the Panchet Beds of India

WHILE preparing an exhibition of nothosaurs and other reptiles of Triassic age from Poland (held at the Geological Society of London on January 28), I realized from Dr. W. E. Swinton's paper[1] that nothosaurs are found at widely separated localities along the shores of the ancient sea of Tethys, from Europe eastwards to Japan. It would thus be reasonable to expect further nothosaur remains anywhere in this belt.

Another band of deposits containing Triassic reptiles is known—part of the Gondwana System—this time stretching from South Africa to Central Asia. This meets Tethys in northern India. Here one should find a mixture of the two faunas and would look for nothosaurs together with a Gondwanaland reptile, which, like them, had a wide distribution and was aquatic. From the literature[2] I found that such an animal was already known from India, namely, the dicynodont *Lystrosaurus*.

Dr. G. de P. Cotter in 1917[3] in his "Revised Classification of the Gondwana System" suggested that the dicynodont material described by Huxley[4] and Lydekker[5] from the Panchet Beds of Bengal belonged to the genus *Lystrosaurus*, and used its presence to correlate these beds with the basal Trias of South Africa. He did not, however, discuss the material as he was concerned solely with stratigraphy. In 1922[6], the late H. C. Das Gupta, professor of geology in Calcutta, in his "Notes on the Panchet Reptile", gave the history of the genus in India and, by means of a detailed discussion of the known skeletal elements, confirmed that Huxley's and Lydekker's material should be placed in *Lystrosaurus*. In addition, he described further *Lystrosaurus* remains that he himself had collected from the Panchet Beds.

Later, Das Gupta[7] described and figured from the same beds a small reptilian vertebra which he considered to be rhynchocephalian, but which is very similar to some of the nothosaur vertebræ from Poland, and is amphiplatyan not amphicœlous as in the Rhynchocephalia. I consider, therefore, that it belongs to a nothosaur.

Thus it would seem that Prof. Das Gupta, even though not aware of it, by finding both nothosaur and *Lystrosaurus* remains in the Panchet Beds, made an important contribution which may well help to effect a closer correlation of the Gondwana System with the Tethyan deposits than has hitherto been possible.

It is good to see that the work of these earlier writers, who had only fragmentary remains for study, should now be so fully confirmed by Dr. P. L. Robinson's account of the recent discovery of more complete remains of *Lystrosaurus* in India[8].

[8] Robinson, P. L., *Nature*, **182**, 1722 (1958).

Many previous writers have suggested that the dicynodont present in the Panchet sandstones might be *Lystrosaurus*. Some, such as de P. Cotter, were not concerned with a review of the dicynodont material available but had some particular stratigraphic axe to grind. Others (Lydekker, Das Gupta, von Huene) have directed attention to certain features of the few fragments available. It is probably not possible to identify *Lystrosaurus* on such fragments. Many characters can be matched individually with those seen in some other dicynodont. A complex of characters, and in particular the key characters of *Lystrosaurus* which are dependent on the relative shortness of the temporal region as compared with length and depth of snout region, can obviously only be assessed on a reasonably complete skull. The matter has been well expressed by Das Gupta[1], " . . . without the discovery of an entire skull, the zoological position of the Panchet reptile cannot be definitely settled. . . ".

I take it that the vertebra diagnosed as nothosaurian by Tarlo is the worn centrum figured by Das Gupta in 1928[1] (Plate II, Fig. 4). The edges of the centrum are so abraded that I feel that a diagnosis of it as originally amphiplatyan is uncertain.

I believe that the description, by Tripathi and Satsangi of the Geological Survey of India, of the new *Lystrosaurus* remains from the lower Panchets, and a careful comparison with the South African and Chinese forms, will be a major contribution to our understanding of the stratigraphy of the Gondwana Group of India. I was delighted to hear from the director of the Geological Survey of India, Dr. B. C. Roy, that he had decided that field work on the Panchets should be continued, and that Tripathi and Satsangi are again making a collection from these rocks. We must wish them success and hope that further discoveries of good specimens of the Panchet fauna will relieve us of the need to burden the literature with identifications made on fragmentary bones.

ENTOMOLOGY

Proepithelial Regeneration in the Midgut of Beetles

The columnar cells of the midgut epithelium in most insects are continually replaced by new cells produced by the division of special regenerative cells. The latter are usually scattered singly or grouped into nidi or else form deep crypts. Pradhan[1], however, described a new process in *Coccinella septempunctata* (Coleoptera, Coccinellidae) and other carnivorous coccinellids where the new cells (pro-epithelial cells) are grouped around large cavities or vacuoles. When the old epithelium is shed, the pro-epithelial cells move into their place. He states that "the presence of this peculiar process of regeneration (pro-epithelial regeneration) in the carnivorous coccinellids and its absence in the herbivorous species forms the most striking difference between the carnivorous and herbivorous midguts". However, in the case of *Epilachna vigintioctopunctata* Fabr., a common herbivorous coccinellid studied by us, pro-epithelial cells grouped around large vacuoles (about 20μ in diameter) could easily be seen (Fig. 1). The vacuoles are present throughout the midgut but are most clearly seen in the middle portion of it.

The function of the vacuoles is obscure. Pradhan[1] speculated that they have a macerative action and are responsible for shedding the old epithelium. In the present material it was noticed that the contents of the vacuoles are not purely watery but give a

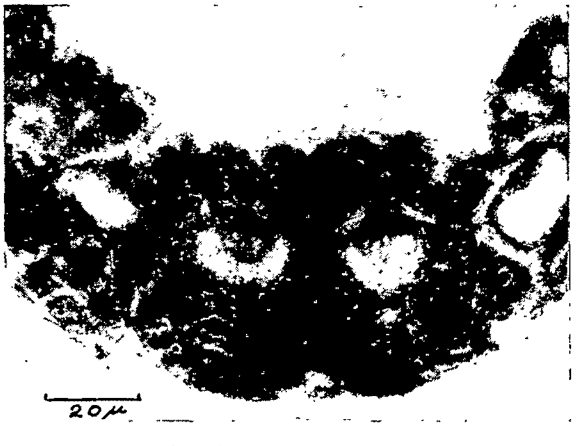

Fig. 1. Section through the middle portion of the midgut of *Epilachna vigintioctopunctata* showing the large vacuoles and the pro-epithelial cells around them

positive periodic acid Schiff reaction of MacManus[2]. Further studies on the vacuoles are in progress.

Respiration of Corixidae (Hemiptera-Heteroptera)

Pterygote insects originally evolved as terrestrial animals, but various families of Hemiptera have since colonized aquatic habitats. Corixids live on the bottom, feeding mainly on algae and detritus. Air carried on the hydrophobe body surface functions as a 'physical gill'[1-4]. The thoracic tracheal system is well developed. The ventrally situated anterior thoracic spiracles occur between the pro- and ptero-thorax. The dorsally placed posterior thoracic spiracles occur laterally to the wing bases. The anterior abdominal spiracles occur dorsally, just posterior to the thorax. On each side these spiracles are joined by a wide, lateral, longitudinal tracheal trunk, which supplies tracheæ to the flight and leg muscles. The tracheæ from each of the ventrally placed abdominal spiracles supply gonads and gut, but, except for the dorsally placed vestigial longitudinal tracheal trunks, are unconnected with other tracheæ of the same or adjacent segments. The passage of gas anteriorly through the thorax (a centre of high oxygen consumption) is largely independent of that through the abdomen where the consumption of oxygen is relatively low.

During submergence, gas is expired from the anterior thoracic spiracles into the space between the pro- and ptero-thorax, to be moved backwards over the surface of the body by the hind legs, which bear special hydrophobe setæ for this purpose. The abdomen is dorso-ventrally flattened to facilitate gaseous exchange between the gas stores and water. Oxygenated gas is inspired through the first pair of abdominal spiracles to pass forwards through the thorax. Considerations of the arrangement of the thoracic sclerites and metathoracic leg muscles show thoracic ventilation is probably automatic during swimming.

Corixids normally come to the surface when deficient in oxygen. By illuminating experimental tanks obliquely from one side it was possible to show corixids are positively phototactic while surfacing, and negatively phototactic when returning to the bottom. This implies that corixids are positively phototactic when deficient in oxygen and negatively phototactic when sufficient oxygen has been obtained. These conclusions are supported by independent evidence of the reactions of corixids to light before and during flight.

Corixids usually occur in shallow water. Hagemann's organs occur immediately in front of the posterior thoracic spiracles. Stimulation of these organs causes surfacing. Under natural conditions this occurs when corixids wander to a depth where there is a danger of water entering the spiracles and flooding the tracheal system. So far no evidence is forthcoming to confirm Hagemann's suggestion that this organ has an auditory function[5].

Corixids renew their superficial gas stores by momentary contact with the atmosphere. At the water surface the pronotum is raised from the front of the hemi-elytra and air rushes over the hydrophobe body surface to dilate the gas stores. Holdgate[6] has shown that aquatic insects with a roughened surface have a high advancing and retreating angle when wetted. During surfacing the rastration of the pronotal and corial surfaces of some species accelerates exposure of the pronotal-hemi-elytral junction and retards the return of water when gas store replenishment is completed.

Cutaneous respiration occurs in the early nymphal instars, but is gradually replaced in later instars and adults by the superficial gas stores acting as a physical gill. As nymphs grow, the increase of cuticular thickness and the reduction in the relative size of the body surface decrease the efficiency of the skin as a respiratory organ. This is compensated by a corresponding increase of relative gas store size: gaseous exchange occurring more rapidly through the air-water interface of the gas stores than through the cuticular body surface.

The physical gill is associated with secondary modifications of body form. The surface gas bubbles make the insect less dense than water. To progress along a horizontal path the hind legs are kicked backwards and upwards. This drives the corixid not only forwards but also slightly downwards to compensate for the tendency to float towards the surface between each leg kick[3]. This mode of locomotion is associated with a forward slant of the thoracic segments and an inward rotation of the hind coxæ: changes which are well illustrated by comparison of the thoracic segments of *Micronecta* and *Corixa*.

While copulating, corixids come to the surface several times. The sexes when joined cannot surface normally because the male is relatively immobile and the female, being ventral to the male, cannot make contact with the surface in the usual way. The male abdomen is asymmetrical and the ædeagus is extruded to the left in *Corixa punctata* and to the right in most British species. Surfacing is accomplished by the pair rolling over on the side of the male asymmetry, thereby allowing the other side of the abdomen ample freedom of movement for gas store replenishment.

In the Corixidae, the reduction of the longitudinal abdominal tracheæ has made it possible for gas to be passed anteriorly through the thorax and for the efficiency of the physical gill to be increased. Compared with other aquatic Hemiptera (for example, Nepidae, Naucoridae and Notonectidae) corixids are less directly dependent upon atmospheric oxygen. Their emancipation from the surface (though not so complete as in *Aphelocheirus aestivalis*[4]) has enabled the family to undergo adaptive radiation to a wide range of aquatic microhabitats and to evolve into more Palæarctic species than occur in the remainder of the Cryptocerata.

FORTHCOMING EVENTS

Wednesday, April 1

Institute of Petroleum (at 61 New Cavendish Street, London, W.1), at 5.30 p.m.—Mr. J. S. Elliott, Mr. N. E. F. Hitchcock and Mr. E. D. Edwards: "Hypoid Gear Lubricants and Additives".

Society of Chemical Industry, Food Group—Nutrition Panel (at 14 Belgrave Square, London, S.W.1), at 6.15 p.m.—Annual General Meeting, followed by Prof. Hugh Nicol: "Facts About Food Supplies".

Institution of Electrical Engineers, London Graduate and Student Section (at Savoy Place, London, W.C.2), at 6.30 p.m.—Mr. S. J. Read: "Discriminators (F.M. Detectors) with particular reference to the Bond Disc".

Society for Analytical Chemistry (at the Chemical Society, Burlington House, Piccadilly, London, W.1), at 7 p.m.—Scientific Papers.

Thursday, April 2

Linnean Society of London (at Burlington House, Piccadilly, London, W.1), at 5 p.m.—Prof. R. E. Holttum: "Growth-habits in Monocotyledons"; Mr. E. M. Marsden-Jones: "Genetics and Pollination of *Anagallis arvensis* subsp. *arvensis* and *A. arvensis* subsp. *Foemina*".

Institute of Refrigeration (at the Institute of Marine Engineers, The Memorial Building, 76 Mark Lane, London, E.C.3), at 5.30 p.m.—Mr. W. R. Hall: "The Measurement and Determination of Noise in Small Refrigerating Machines".

Institution of Electrical Engineers (at Savoy Place, London, W.C.2), at 5.30 p.m.—Discussion on "Women in Engineering" opened by Sir Willis Jackson, F.R.S.

Society of Chemical Industry, Microbiology Group (at 14 Belgrave Square, London, S.W.1), at 6 p.m.—Annual General Meeting, followed by Dr. P. W. Brian, F.R.S.: "Some Ecological Consequences of Production of Extracellular Metabolites by Micro-organisms".

Polarographic Society (at "The Duke of York", 8 Dering Street, London, W.1), at 7 p.m.—Informal Discussion Meeting on "Some Polarographic Problems Encountered in Industrial Medicine" introduced by Mr. K. Baker and Mr. L. King.

Friday, April 3

Biochemical Society (in the Department of Biochemistry, University College, Gower Street, London, W.C.1), at 10.30 a.m.—Annual General Meeting.

Manchester Statistical Society, Industrial Group (in the Portico Library, 57 Mosley Street, Manchester), at 6 p.m.—Mr. L. H. C. Tippett: "Recent Developments in the Measurements of Productivity in the Textile Industry".

Society of Dyers and Colourists, London Section (at the George Hotel, Luton), at 7 p.m.—Dr. T. Vickerstaff: "Recent Developments in Dyeing".

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Chair of Philosophy tenable in the Durham Division of the University—The Registrar, University Office, 46 North Bailey, Durham (April 9).

Lecturers (with a good honours degree and relevant teaching experience) in Geography, Chemistry, Physics and Mathematics at the Nigerian College of Arts, Science and Technology—The Council for Overseas Colleges, 12 Lincoln's Inn Fields, London, W.C.2 (April 10).

Research Fellow (with an interest in physical-organic chemistry and some postgraduate experience in preparative chemistry) in the Department of Chemistry—The Registrar, Queen Mary College (University of London), Mile End Road, London, E.1 (April 10).

Senior Lecturer (with a good honours degree and some previous teaching experience) in Mathematics—The Director of Education, The Polytechnic, 309 Regent Street, London, W.1 (April 10).

Lecturer in Organic Chemistry—The Clerk to the Governors, Chelsea College of Science and Technology, Manresa Road, London, S.W.3 (April 13).

Assistant Experimental Officer or Experimental Officer (zoologist, preferably with an interest in entomology) at the Freshwater Fisheries Laboratory, Pitlochry, to be a member of a small team working on the bottom fauna of freshwaters—The Establishment Officer, Scottish Home Department, Room 364, St. Andrew's House, Edinburgh 1 (April 15).

Professor of Applied Physics in the Durham Division for a new Department of Applied Physics due to open in October 1960—The Registrar, University Office, 46 North Bailey, Durham (April 16).

Lecturer (graduate with qualifications, training and teaching experience in mathematics) in the Department of Education—The Registrar, The University, Leicester (April 18).

Research Assistant (with an honours degree in statistics or an honours degree in mathematics, together with some knowledge of statistical methods) in Statistics, for duties which include computation, programming for a computer, demonstration and a small amount of teaching—The Registrar, The University, Sheffield (April 18).

Research Fellow (with Ph.D. or equivalent experience in an appropriate subject, such as biochemistry, animal or plant physiology) at the Marine Biology Station, for research into mechanisms of toxicity—The Registrar, University College of North Wales, Bangor (April 18).

Assistant Lecturer in Physics—The Registrar, University College of North Staffordshire, Keele, Staffs (April 20).

Lecturer (preferably medically qualified) in Physiology—The Secretary, The University, Aberdeen (April 20).

Technician (preferably with experience in workshop practice or in histological techniques) at the Marine Biology Station—The Registrar, University College of North Wales, Bangor (April 20).

University Demonstrators and Departmental Demonstrators in Biochemistry, Ecology, Physiology and Virology—The Sherardian Professor of Botany, Botany School, The University, Oxford (April 20).

Tutor or Lecturer (woman, with special qualifications in either experimental or theoretical physics) in Physics—The Treasurer, Somerville College, Oxford (April 21).

Senior Lecturer or Lecturer in Philosophy at the University of Khartoum—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (April 23).

Chair of Physiology at Bedford College—The Academic Registrar, University of London, Senate House, London, W.C.1 (April 24).

Research Assistant (with a first- or second-class honours degree in chemistry) in the Chemistry and Metallurgy Department—The Principal, Coventry Technical College, Butts, Coventry (April 24).

Lecturer or Assistant Lecturer in the Department of Zoology and Comparative Physiology—The Registrar, The University, Birmingham 15 (April 25).

Assistant Lecturer in Inorganic Chemistry—The Registrar, The University, Hull (April 27).

Reader in Geography at Queen Mary College—The Academic Registrar, University of London, Senate House, London, W.C.1 (April 27).

Clinical Lecturer (medical graduate with experience in bacteriology, immunology or virology, and in research methods) in Microbiology—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1, or The Registrar, University of Otago, Dunedin, New Zealand (New Zealand, April 30).

Research Assistant (with an honours or good pass degree in agriculture or equivalent) in the Department of Agriculture, for grazing studies in connexion with grassland irrigation—The Registrar (Room 22, O.R.B.), The University, Reading (April 30).

University Lecturer in History of Science—Mr. R. F. Holmes, The Old Schools, The University, Cambridge (April 30).

Senior Lecturer in Physics—The Registrar, The University, Hull (May 1).

Assistant Lecturer or Lecturer (preferably with a special interest in mineralogy and petrology or in economic geology) in Geology at the University College of Ghana—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (May 10).

Assistant (Grade B) to teach Physics, Mathematics and Chemistry to Advanced Level G.C.E.—The Principal, North-West Kent College of Technology, Miskin Road, Dartford.

Clinical Biochemist, to assist in research into metabolic changes accompanying burns—The Group Secretary, Booth Hall Children's Hospital, Blackley, Manchester 9.

Demonstrator in the Plant Physiology Department, for teaching and to carry out research—The Professor of Plant Physiology, Imperial College of Science and Technology, Prince Consort Road, London, S.W.7.

Lecturer in Botany—The Secretary, Queen Elizabeth College (University of London), Campden Hill Road, London, W.8.

Lecturer in Chemistry; a Lecturer in Physics; and Grade B Assistants in Chemistry, Physics and Mathematics—The Principal, Reading Technical College, King's Road, Reading.

Lecturer (with proved research ability in physical metallurgy or in metal physics) in Physical Metallurgy—Prof. J. G. Ball, Metallurgy Department, Imperial College of Science and Technology, London, S.W.7.

Master to teach Mathematics up to Scholarship Level—The Headmaster, Cheltenham College.

Mathematics Master, principally to share Sixth Form teaching up to Scholarship Standard with some work in the Middle School—The Head Master, University College School, Frognal, Hampstead, London, N.W.3.

Research Assistant (science graduate, preferably with previous experience in serology and blood-group studies), to carry out experimental work in animal blood-groups—The Administrative Secretary, School of Veterinary Medicine, The University, Madingley Road, Cambridge.

Scientific Assistant (Abstractor) (with a degree in agriculture or natural science and a knowledge of languages)—The Director, Commonwealth Bureau of Pastures and Field Crops, Hurley, Berkshire.

Scientific Officer (Petrologist) (with a first- or good second-class honours degree in geology and at least five years postgraduate experience in petrology) in the Geological Survey Department, Federation of Nigeria, for duties which will include petrological and mineralogical work in the Geological Survey Laboratories, with good opportunities for research—The Director of Recruitment, Colonial Office, London, S.W.1, quoting BCD.105/14/06.

Senior Assistant in Agricultural Chemistry or Lecturer (Assistant, Grade II) in Agricultural Chemistry—The Clerk to the Governors, Essex Institute of Agriculture, Writtle, near Chelmsford, Essex.

Senior Lecturer in Electrical Power (Electricity Supply); a Senior Lecturer in Electrical Machines; a Lecturer in Electronics (Electrical Computing); a Lecturer in Electrical Engineering (Utilization); and an Assistant Lecturer in Electronics—The Secretary, Northampton College of Advanced Technology, St. John Street, London, E.C.1.

Senior Lecturer (well qualified physicist and preferably with some experience of the application of physics in industry) in Physics—The Registrar, Bradford Institute of Technology, Bradford 7.

Vice-Principal (with high academic qualifications, responsible experience in administration and teaching, and preferably some industrial experience), to assist in the general administration of the College—The Principal, Cambridgeshire Technical College and School of Art, Collier Road, Cambridge.

Great Britain and Ireland

Electrified Production, No. 1 (November, 1958). A quarterly illustrated newsletter. Pp. 4. (London: Electrical Development Association, 1958.) [191

British Council. 1959–60 Scholarships Abroad: Scholarships offered to British Students by Foreign Governments and Universities. Pp. iii+37. (London: British Council, 1959.) [191

Department of Scientific and Industrial Research: Lending Library Unit. L. L. U. Translations Bulletin, January 1959. Pp. iii+70. Published monthly. Annual subscription: 53*s.* including postage. Single issues 4*s.* (London: H.M. Stationery Office, 1959.) [191

Ministry of Agriculture, Fisheries and Food. Fishery Investigations, Series 2, Vol. 21, No. 8: An Account of the Fishing Gear of England and Wales. By F. M. David. Pp. v+165. (London: H.M. Stationery Office, 1958.) 35*s.* net. [191

Building Research Station Digest No. 117: Condensation and the Design of Factory Roofs. Pp. 4. (London: H.M. Stationery Office, 1959.) 3*d.* [261

Imperial College of Science and Technology. Code of Practice Against Radiation Hazards. Revised edition. Pp. iii+27. (London: Imperial College of Science and Technology, University of London, 1958.) [261

Ministry of Supply. Reports on Plastics in the Tropics. No. 10: Synthetic Resin Bonded Laminated Sheet. Pp. 49. (London: H.M. Stationery Office, 1958.) 6*s.* net. [261

Philosophical Transactions of the Royal Society of London. Series B: Biological Sciences. No. 689, Vol. 242 (22 January 1959): Studies of the Post-Glacial History of British Vegetation. By H. Godwin. 14: Late-Glacial Deposits at Moss Lake, Liverpool. Pp. 127–149+plates 3 and 4. 10*s.* No. 690, Vol. 242 (22 January 1959): A Study of the Development of the Head and Pharynx of the Larval Urodele *Hynobius* and Its Bearing on the Evolution of the Vertebrate Head. By H. Fox. Pp. 151–205+plates 5–7. 27*s.* 6*d.* (London: Royal Society, 1959.) [261

Forestry Commission. Forest Record No. 38: Design of Poplar Experiments. By J. N. R. Jeffers. Pp. 19. (London: H.M. Stationery Office, 1958.) 1*s.* 9*d.* [261

Ministry of Education Pamphlet No. 36: Teaching Mathematics in Secondary Schools. Pp. viii+154. (London: H.M. Stationery Office, 1958.) 6*s.* net. [261

Glasshouse Crops Research Institute. Annual Report 1957. Pp. 161. (Littlehampton: Glasshouse Crops Research Institute, 1958.) 10*s.* [261

Department of Scientific and Industrial Research: Hydraulics Research Station. Hydraulics Research Paper No. 1: Resistance of Fluids Flowing in Channels and Pipes. By Peter Ackers. Pp. iv+39. 8*s.* 6*d.* net. Hydraulics Research Paper No. 2: Charts for the Hydraulic Design of Channels and Pipes. By Peter Ackers. Pp. iv+46. 12*s.* net. (London: H.M. Stationery Office, 1958.) [261

Mathematics Before Newton. By Prof. A. R. Manwell. (Inaugural Lecture given in the University College of Rhodesia and Nyasaland.) Pp. 57. (London: Oxford University Press, 1959.) 4*s.* net. [281

Department of Scientific and Industrial Research: Building Research Station. National Building Studies—Research Paper No. 27: Noise in Three Groups of Flats with Different Floor Insulations. By P. G. Gray, Ann Cartwright and P. H. Parkin. Pp. iv+61. (London: H.M. Stationery Office, 1958.) 4*s.* net. [281

Bulletin of the British Museum (Natural History). Entomology. Vol. 7, No. 8: New or Little Known Butterflies from Malaya. By Lt.-Col. J. N. Eliot. Pp. 369–391+plate 10. 8*s.* Zoology. Vol. 5, No. 6: Ear Plug Laminations in Relation to the Age Composition of a Population of Fin Whales (*Balaenoptera physalus*). By P. E. Purves and M. D. Mountford. Pp. 123–161+plates 5 and 6. 20*s.* (London: British Museum (Natural History), 1959.) [291

The Engineer Buyers Guide 1959. Pp. 960. (London: *The Engineer*, 1959.) 7*s.* 6*d.* [301

Imperial College of Science and Technology. Post graduate Courses, 1959–60. Pp. xii+111. (London: Imperial College of Science and Technology, University of London, 1959.) [301

British Hat and Allied Feltmakers Research Association. Eleventh Annual Report of the Director of Research for the year ended August, 1958. Pp. 20. (Manchester: British Hat and Allied Feltmakers Research Association, 1959.) [301

University of Birmingham. Report of the Vice-Chancellor and Principal for the calendar year 1958. Pp. 26. Accounts for the year ended 31st July, 1958. Pp. 36. Report of the Proceedings of the Council of the University for the year ended 31st December 1958. Pp. 18. (Birmingham: The University, 1958 and 1959.) [301

Philosophical Transactions of the Royal Society of London. Series B: Biological Sciences. No. 961, Vol. 242 (29 January 1959): A New Armoured Amphibian from the Upper Permian of East Africa. By A. L. Panchen. Pp. 207–281. (London: Royal Society, 1959.) 25*s.* [301

Other Countries

Museum of Comparative Zoology at Harvard College. Breviora. No. 97 (October 27, 1958): Fusion of Cervical Vertebrate in the *Erethizontidae* and *Dinomyidae*. By Clayton E. Ray. Pp. 11. No. 98 (December 12, 1958): Two New Species of *Bathylagis* from the Western North Atlantic with Notes on other species. By Daniel M. Cohen. Pp. 9. No. 99 (December 19, 1958): A New Subspecies of *Chamaeleo jacksoni* Boulenger and a Key to the Species of Three-Horned Chamaeleons. By A. Stanley Rand. Pp. 8. No. 100 (December 23, 1958): On the Pineal Organ of the Tuna, *Thynnus thynnus* L. By Uno Holmgren. Pp. 5. (Cambridge, Mass.: Museum of Comparative Zoology at Harvard College, 1958.) [261

United States Department of Agriculture. Agriculture Information Bulletin No. 194: Salt Tolerance of Grasses and Forage Legumes. By Leon Bernstein. Pp. 7. (Washington, D.C.: Government Printing Office, 1958.) 5 cents. [261

Rensselaer Polytechnic Institute, Troy, New York. Annual Report, 1957–1958. Pp. 68. (Troy, New York: Rensselaer Polytechnic Institute, 1958.) [261

Regional Research Laboratory, Hyderabad. Annual Report, 1957–1958. Pp. ix+136. (Hyderabad: Regional Research Laboratory, 1958.) [261

National Research Development Corporation of India. Fourth Annual Report and Statement of Accounts for the period ending 31st March, 1958. Pp. 20. (New Delhi: National Research Development Corporation of India, 1958.) [261

Canada: Department of Mines and Technical Surveys. Geological Survey of Canada. Bulletin 43: Stratigraphy of the Lewes River Group (Triassic), Central Laberge Area, Yukon Territory. By E. T. Tozer. Pp. v+28 (3 plates). 50 cents. Bulletin 46: Contributions to Canadian Palynology. Part 1: The Use of Palynological Studies in Pleistocene Stratigraphy. Part 2: Non-glacial Deposits in the St. Lawrence Lowlands, Quebec. Part 3: Non-glacial Deposits along Missinaibi River, Ontario. By J. Terasmae. Pp. vi+35+3 plates. 50 cents. (Ottawa: Queen's Printer, 1958.) [261

Tanganyika: Department of Geological Survey. Records of the Geological Survey of Tanganyika, Vol. 5, 1955. Pp. iii+99+23 plates. Shs. 15. G.S. Map No. 1134: Manda. G.S. Map No. 1168: Tukuyu. (Dar-es-Salaam: Government Printer, 1958.) [261

Department of Agriculture, Fiji. Bulletin No. 32: Copra Driers: Principles of Copra Drying and Practical Applications. Pp. iv+36. (Suva: Government Printer, 1958.) 3*s.* [261

Conseil Permanent International pour l'Exploration de la Mer, Charlottenlund Slot, Danemark. Fiches d'Identification du Zooplancton, Nos. 71–80. Rédigé par J. H. Fraser. Pp. 38. (Copenhagen: Andr. Fred Høst & Fils, 1958.) 15.00 kr. [261

National Academy of Sciences—National Research Council, Washington. A Commentary on the Report of the United Nations Scientific Committee on the Effects of Atomic Radiation. (Committee on Pathologic Effects of Atomic Radiation, Report No. 2.) Pp. i+5. (Publication 647.) (Washington, D.C.: National Academy of Sciences—National Research Council, 1959.) [261

Companhia de Diamentes de Angola (Diamang.) Servicos Culturais. Dundo-Lunda-Angola. Museu do Dundo. Subsidios para 1 Estudo da Biologia na Lunda. Publicacoes Culturais No. 40: Estudos Diversos (XV). Pp. 147. (Lisboa: Companhia de Diamantes de Angola, 1958.) [261

Proceedings of the Symposium on Prestressed Concrete as Applied to Buildings, held at the Central Building Research Institute, Roorke, (U.P.), India, 10th–12th February, 1958. (*Indian Construction News*, Vol. 7, No. 8). Pp. 136. (Calcutta: Technical Journals of India Private, Ltd., 1958.) [261

Berichte des Deutschen Wetterdienstes. Nr. 48 (Band 7): Untersuchungen über den Nachtlichen Energietransport und Energiehaushalt in der Bodennahen Luftschicht bei der Bilding von Strahlungsnebeln. Von Helmut Kraus. Pp. 25 (mit 9 Abbildungen und 7 Tabellen im Text und 10 Tafeln im Anhang.) (Offenbach: Deutschen Wetterdienstes, 1958.) [261

Journal of Applied Mathematics and Mechanics, Vol. 22, No. 1. Translated from the Russian. Pp. ii+202. Issued bi-monthly or corresponding to the number of original Russian issues per annum. One volume per year. Approximately 1,200 English pages. Annual subscription rate: 35 dollars; £12 10*s.* 0*d.* (New York and London: Pergamon Press, 1958.) [261

Proceedings of the California Academy of Sciences. Fourth Series. Vol. 29, No. 9: Bibliography, Cartography, Discovery, and Exploration of the Islas Revillagigedo. By Adrian F. Richards and Bayard H. Brattstrom. Pp. 315–360. Vol. 29, No. 10: A Revision of the Species of *Pandeleteius* Schönherr and *Pandeleteinus* Champion of America North of Mexico (Coleoptera: Curculionidae.) By Anne T. Howden. Pp. 361–421+2 plates. (San Francisco: California Academy of Sciences, 1959.) [261

Kungl. Tekniska Högskolans Handlingar. (Transactions of the Royal Institute of Technology, Stockholm.) Nr. 129: Investigations of the Disk-Loaded and Helical Waveguide. By Bengt T. Henoch. Pp. 84. (Stockholm: Elanders Boktryckeri Aktiebolag, 1958.) 9 kronor. [281

United States Department of the Interior: Geological Survey. Bulletin 1071-B: Geologic Reconnaissance of San Clemente Island, California. By F. H. Olmsted. Pp. iii+55–68+plate 1. 75 cents. Bulletin 1071-C: Origin of Steps on Loess-Mantled Slopes. By James C. Brice. Pp. iii+69–85+plates 2 and 3. 25 cents. Bulletin 1082-A: Zirconium and Hafnium in the Southeastern Atlantic States. By John B. Mertie, Jr. Pp. iii+28. 15 cents. Professional Paper 316-B: Interpretation of an Aeromagnetic Survey of Indiana. By John R. Henderson, Jr., and Isidore Zietz. Pp. iii+19–37+plates 4 and 5. 75 cents. (Washington, D.C.: Government Printing Office, 1958.) [281

INDEX

ABBOTT, Bernard C., and others : Electrical Response to Illumination of the Euphausiid Crustacean Eye, 1820
Abd-El-Malek, A. S. (Soliman, F. A., and) : Influence of Temperature and Light on Reproduction in Male Rats, 266
Abd-el-Wahab, Dr. A.: A New Method for Delaying Pupation in *Drosophila melanogaster*, 127
Abels, Dr. J., and others : Ethylenediamine Tetraacetate and the Intestinal Absorption of Vitamin B_{12}, 1395
Abelson, Dr. Philip H. : Elected a member of the United States National Academy of Sciences, 1575
Abercrombie, D : Phonetics, *review*, 209
Aberdeenshire Dee : *Vibrio* spp. in Finnock from the (Isabel W. Smith), 1409
Aberrant Cell Walls and of Spores : Formation of, by the Growing Yeast Protoplast (A. A. Eddy and D. H. Williamson), 1101
Aberration of the Connective Tissue : Human Muscular Dystrophy as an (Prof. Geoffrey H. Bourne and M. Nelly Golarz), 1741
Aberrations (Chromosomal) : A New Physical Method of creating (Dr. John H. Heller and Dr. A. A. Teixeira-Pinto), 905
Aberystwyth Area : The Soils of the (Welsh Soils Discussion Group Discussion on), 865
Abnormal Development of the Basis in *Balanus amphitrite* var. *stutsburi* Darwin (Dr. H G. Stubbings), 1282
Abnormal Haemoglobins (Normal and Doubly) : Formation of, by Recombination of Haemoglobin I with S and C (Constituents of Human Haemoglobin), (Dr. Harvey A. Itano and Elizabeth Robinson) 1799
Abnormal Proteins in Myeloma and Macroglobulinaemia : Starch Gel Electrophoresis Studies on (Dr. J. M. Fine and Dr. R. Creyssels), 392
Abnormal Resistance of *Poria vaillantii* (D. C. ex Fr.) Cke. Strains to Copper–Chrome–Arsenate Wood Preservatives (E. W. B. Da Costa), 910
Abnormality : A Rare Sperm—'Corkscrew-sperms' associated with Sterility in Bulls (Dr. Erik Blom), 1280
Abnormality in the Skin of Sheep (Mary Dempsey and G. H. Green), 909
Aboriginal Art, *review* by Dr. Phyllis Kaberry, 1080
Abscission-Accelerating Substance in Senescent Leaves : Identity of the (Daphne J. Osborne), 1593
Abscission-Accelerators in Lupins (*Lupinus luteus* L.), (R. F. M. Van Steveninck), 1246
Absence of Gibberellin-like Substances in Filtrates of *Marasmius perniciosus* Stahel (Witch Broom Disease of Cacao), (W. F. Dudman and R. Nichols). 899
Absence of Homotransplantation Reaction : Antibody Formation by Isolated Spleen Cells transferred to Recipients in (Dr. Z. Trnka and I. Říha), 546
Absence of a Relation between Lipogenesis and Ketogenesis *in vivo* (Dr. P. A. Mayes), 540
Absolute Measurement of the Intensity of the (111) Reflexion for Diamond (Prof. R. Brill and H Zandy), 1387
Absorbing Bodies : Initiation of Thermal Reactions by the Flash Illumination of (Dr. J. L. Lundberg and Dr. L. S. Nelson), 1560
Absorption of Alkali Cations by Plant Tissue Cultures (Dr. J. F. Sutcliffe and E. R. Counter), 1513
Absorption of Orally Administered Vitamin B_{12} : Effect of D-Sorbitol on the (Dr. J. N. Marshall Chalmers and N. K. Shinton), 120
Absorption of Radioiodine through the Bladder-Wall in the Rabbit (Oskar Andrysek and Ota Schück), 893
Absorption (Faecal), of Radioactive Ferric Chloride : Effect of Dietary Phytate on (Dr. Henry Foy, Athena Kondi and W. H. Austin), 691
Absorption (Intestinal), of Vitamin B_{12} : Ethylenediamine Tetraacetate and the (Dr. J. Abels, M. G. Woldring, H. O. Nieweg, J. G. Faber and J. A. de Vries), 1394
Absorption Spectra and Associated Photoconductivity of Pure and Decomposed Crystals of Thallous Azide (B. L. Evans and A. D. Yoffe), 1241
Absorption Spectra (Infra-red and the Near Ultra-violet), of Polyphenyl Derivatives of the Elements of Groups IV*b* and V*b* (Dr. C. N. R. Rao, J. Ramachandran, M. S. C. Iah, S. Somasekhara and T. V. Rajakumar), 1475
Absorption Spectrum and Decay Kinetics of the Metastable State of Chlorophyll *b* (Prof. Stig Claesson, Lars Lindqvist and Bertil Holmström), 661
Academic Freedom and the Universities of South Africa, 1551
Academic Studies : The Scope of Physical Anthropology and its Place in—a Symposium held at the Ciba Foundation, 1957 (edited by D. F. Roberts and J. S. Weiner), *review* by Dr. Kenneth Little, 70
Academy of Sciences of the U.S.S.R. : An English translation of the *Astronomical Journal* of the, to be published by the American Institute of Physics in co-operation with the National Science Foundation, under the title *Soviet Astronomy—AJ*, 1164
  A. S. Popov Gold Medal awarded to Dr. Louis Essen, 1502
  Fizika Tverdogo Tela (Soviet Physics—Solid State), No. 1, 1717
Accelerating (Abscission-) Substance in Senescent Leaves : Identity of the (Daphne J. Osborne), 1593
Acceleration of Artificial Satellites : Corpuscular Radiation and the (Dr. Luigi G. Jacchia), 1662
Acceleration of Ciliary Activity by Negative Air Ions : An Enzymatic Basis for the (Prof. A. P. Krueger and Richard F. Smith), 1332
Acceleration (Orbital), of Artificial Satellites : Two Atmospheric Effects in the (Dr. Luigi G. Sacchia), 526
Accelerators (Abscission-) in Lupins (*Lupinus luteus* L.), (R. F. M. Van Steveninck), 1246
Accelerators (High Energy), and Instrumentation (C. E. R. N. International Conference on), 1783
Acceptance (Food) : Flavor Research and—a Survey of the Scope of Flavor and Associated Research compiled from papers presented in a series of Symposia given in 1956-57, *review* by Dr. Magnus Pyke, 351
Accessory Limb Formation in Urodeles : Delayed Denervation and (Dr. Laurens N. Ruben), 765
Accident (Windscale Reactor) : Measurements at Leeds following the—Iodine-131 in Human Thyroids and Iodine-131 and Caesium-137 in Milk (Dr. P. R. J. Burch), 515 ; Increase in Background Gamma-Radiation and its Correlation with Iodine-131 in Milk (Prof. F. W. Spiers), 517
Accidents (Road) : Research on the Prevention of, 649
Acephaline Gregarine (*Apolocystis elongata*, Phillips and MacKinnon) : Observations by Electron Microscopy on the Structure of an (Dr. D. Lacy and H. B. Miles), 1456
Acetabularia : Action of Auxins on, and the Effect of Enucleation (Prof. Kenneth V. Thimann and Dr. Kurt Beth), 946
Acetamidomalonate (Diethyl) : Asymmetric Hydrolysis of, by Chymotrypsin (Prof. Saul G. Cohen and Lucille Altschul), 1678
2-^{14}C-Acetate and ^{14}C-Glucose in *Trichoderma viride* : Synthesis of Long-Chain Fatty Acids from (Dr. W. Mary Crombie and P. E. Ballance), 1195
Acetate (Cellulose), as a Medium for Immuno-Diffusion (R. Consden and J. Kohn), 1512
Acetate (Cellulose) Membranes suitable for Osmotic Measurements (M. F. Vaughan), 43
Acetate (Cellulose) Membranes used for Zone Electrophoresis : Regeneration of (Dr. S. Jacobs), 1326
Acetoacetate Metabolism of Liver Homogenates of Normal and Alloxanized Rats : Action of Nicotinamide on (S. Eser, S. Tekman and A. Araz), 184
Acetoacetate (Glucose-*cyclo*-), as a Precursor of Ascorbic Acid in Germinating Green Gram (Prof. M. C. Nath and M. L. Belkhode), 1258
Acetobacter xylinum : Synthesis of Cellulose in Ethanol Extracts of (Dr. J. Ross Colvin), 1135
Acetone : Relaxation of Glycerol-treated Muscle Fibres by (Dr. Setsuro Ebashi and Dr Fumiko Ebashi), 687
Acetone (Cobalt Chloride–Water–) : Existence of Two Liquid Phases in the System (Dr. J. N. Murrell, Dr. L. I. Katzin and B. L. Davies), 459
Acetylcholine : Distinction between Sodium and Potassium in Change in Permeability effected by Lipid-soluble Analogues of (Dr. Wolf D. Dettbarn), 465
Acetylcholine Release : Failure of, in Tick Paralysis (Patricia Emmons and Prof. H. McLennan), 474
Acheson Colloid, Ltd. : A Dispersion of Polytetrafluoroethylene under the trade name of 'Emralon', 1501
Acheta commodus W. : A Rapid Method for examining Diapause Embryos of (T. W. Hogan), 269
Acid from Arabinose and Xylose : Production of, by Strains of *Azotobacter* (Vagn Jensen), 1536
Acid Mucopolysaccharides of Normal Urine (Dr. J. F. Heremans, J. P. Vaerman and M. Th. Heremans), 1606
Acid Phosphatase-elevating Activity : Fractionation of Brain Extracts for (Dr. V. Schreiber, Prof. J. Charvát, V. Kmentová and M. Rybák), 473
Ackeret, Prof. J. : Honorary Fellowship of the Royal Aeronautical Society conferred on, 1648
Ackerknecht, Prof. Erwin H. : The Quintessence of Paracelsus, *review*, 1147
Ackroyd, J. F. : Immunological Aspects of Allergic Disorders (Allergic Thrombocytopenic Purpura due to Antazoline), 297
Acoustic Orientation of Bats and Men : Listening in the Dark, the (Prof. Donald R. Griffin), *review* by Prof. R. J. Pumphrey, 1554
Acoustics : Musical (Prof. E. G. Richardson), 1293
  Of What Use Is, to the Musician ? (Acoustics Group of the Physical Society Discussion on), 1293
Acoustics (Physical), and the Properties of Solids (Dr. Warren P. Mason), *review* by Prof. E. G. Richardson, 1221
Acquired Characters : Canalization of Development and Genetic Assimilation of (Prof. C. H. Waddington), 1654
Acquired Immunological Tolerance of Heterografts (Dr. Milan Hašek, Tomáš Hraba and Jan Hort), 1199
Acridine Orange : Fluorescence of Tissue Culture Cells stained with (U. N. Joshi and Dr. K. S. Korgaonkar), 400
Acta Biologica Cracoviensia, Vol. I, No. 1 (Polish Academy of Sciences), 1781
Actidione (Cycloheximide) : Reversal of Antibiotic Action of, by Bivalent Metal Ions (M. Blumauerová and J. Stárka), 261
Action of Auxins on *Acetabularia* and the Effect of Enucleation (Prof. Kenneth V. Thimann and Dr. Kurt Beth), 946
Action of the Contact γ-Aluminium Oxide/Platinum : Structure and Mode of (Prof. Alfons Krause), 1615
Action of Diphosphopyridine Nucleotidases : Mechanism of (Prof. Spyridon G. A. Alivisatos), 1034
Action of Insulin : Mechanism of (A. Dunn, N. Altszuler, Prof. R. C. de Bodo, R. Steele, D. T. Armstrong and J. S. Bishop), 1123

Action of Light on Visual Pigments—Vertebrate Lumi- and Meta-Rhodopsins (Dr. Ruth Hubbard, Paul K. Brown and Dr. Allen Kropf), 442 ; Lumi- and Meta-Rhodopsins of Squid and Octopus (Dr. Allen Kropf, Paul K. Brown and Dr. Ruth Hubbard), 446 ; Chicken Lumi- and Meta-Iodopsin (Dr. Ruth Hubbard and Dr. Allen Kropf), 448
Action of Nicotinamide on Acetoacetate Metabolism of Liver Homogenates of Normal and Alloxanized Rats (S. Eser, S. Tekman and A. Araz), 184
Action of Pyrrolizidine Alkaloids on the Neuro-Muscular Junction (Dr. C. H. Gallagher and Dr. J. H. Koch), 1124
Action of Ultra-violet Light on Skin—Effect of the Histamine Liberator 48/80 and Methotrimeprazine (Prof. S. Claesson, G. Wettermark and L. Juhlin), 1451
Action (Antibiotic), of Cycloheximide (Actidione) : Reversal of, by Bivalent Metal Ions (M. Blumauerová and J Stárka), 261
Action (Anticoagulant), of Fibrin Surfaces on Mammalian Blood (Dr. A. L. Copley, D. Steichele, M. Spradau and R. S. Thorley), 1683
Action (Anti-Thyroid), of β-Aminoethyl*iso*thiouronium Dibromide in Rats (John Osmer, Dr. Robert B. Jennings and Dr. Robert M. Dowben), 470
Action (Bacterial), in Pond-stored Logs (Eric L. Ellwood and Barton A. Ecklund), 1206
Action (Catalytic), of Copper in the Alkaline Autoxidation of Cellulose at Low Alkali Concentration (R. I. C. Michie and Dr. S. M. Neale), 534
Action (Gene), in Erythrocyte Deficiency of Glucose-6-phosphate Dehydrogenase—Tissue Enzyme-Levels (Prof. Paul A. Marks, Dr. Ruth T. Gross and Dr. Ruth E. Hurwitz). 1266
Action (Inhibitory), of Amino-Acid Esters on the Production of Extracellular Amylase by *Penicillium chrysogenum* (Dr. L. Horváth, S. Bajusz and A. Szentirmai), 477
Action (Mode of), and Biological Properties of the S-(Methylcarbamyl) Methyl O, O-Dimethyl-Dithiophosphate (R. Santi and P. de Pietri-Tonelli), 398
Action (Protective), of Cystamine and 5-Hydroxytryptamine in Irradiated Rats : Effect of High Oxygen Pressure on the (H. A. S. van den Brenk and Ruth Moore), 1530
Action (Short-term), of Pepsin at Room Temperature : Splitting of the Electrophoretic Pattern of Serum Albumin during (E. Annau), 190
Actions (Pharmacological), of γ-Butyrobetaine (Dr. E. A. Hosein and Prof. H. McLennan), 328
Activated Sera : Granulocyte Precipitins of Human Tissues and (Dr. Leonhard Korngold, Gerda Van Leeuwen and Daniel G. Miller), 330
Activation of Amino-Acids in relation to the Synthesis of Silk Proteins (Prof. J. Heller, Dr. P. Szafrański and Dr. E. Sulkowski), 397
Activation of Thionophosphates by Liver Microsomes (Prof. R. D. O'Brien), 121
Activation (Organ), by Stress : Target (Prof. Jenö Kramár, Harry H. McCarthy, Margarete Simay-Kramár and Anthony J. Carnazzo), 1522
Activation (Stress), of Adrenal Glomerulosa (Dr. M. Hill, K. Dvořák and M. Pospíšil) 1819
Activator for Phospholipase *D* : Isolation of an (Herbert Weiss, Herbert E. Spiegel and Elwood Titus), 1393
Active (Immunochemically), Cross-linked Polystyrene (L. H. Kent and J. H. R. Slade), 325
Active (Optically), Fluorite Films (Niels O. Young and Jakym Kowal), 104
Active Substances (Biologically) : 'Pheromones', a New Term for a Class of (Dr. P. Karlson and Prof M. Lüscher), 55
Activities (Haemolysin and Complement-fixing) : Comparison of the Formation of the Complex, Sensitized Erythrocyte-Complement ($EAC'_{1,4,2}$) in Haemolytic Systems differing in their (Dr. Harold S. Goodman), 331
Activity of 10-Hydroxydecenoic Acid from Royal Jelly against Experimental Leukaemia and Ascitic Tumours (Prof. Gordon F. Townsend, Dr. Joseph F. Morgan and Dr. Barbara Hazlett), 1270
Activity (Acid Phosphatase-elevating) : Fractionation of Brain Extracts for (Dr. V. Schreiber, Prof. J. Charvát, V. Kmentová and M. Rybák), 473
Activity (Aminopeptidase), in Cancer Cells (R. G. J. Willighagen and H. T. Planteydt), 263
Activity (Anti-Tumour), of 5-Mercaptouracil (Thomas J. Bardos, Albert Segaloff and Julian L. Ambrus), 612
Activity (Antiviral), of Lysozyme (Prof. Rodolfo Ferrari, Dr. Carlo Callerio and Dr. Giuseppe Podio), 548
Activity (Arginine Esterase), of 'Blood Thromboplastin' (Phyllis M. Arscott, J. L. Koppel and John H. Olwin), 753
Activity (Biological), of L-Tryptophan Esters (Dr. Giulio C. Perri, Louis Kaplan and C. Chester Stock), 116
Activity (Blood-clotting), of the Venom of *Bothrops jararaca* (Dr. Olga B. Henriques, Dr. Fajga R. Mandelbaum and Dr. S. B. Henriques), 114
Activity (Cardiac) : Nucleotide Metabolism in (Dr. Philip A. Khairallah), 181
Activity (Ciliary), by Negative Air Ions : An Enzymatic Basis for the Acceleration of (Prof. A. P. Krueger and Richard F. Smith), 1332
Activity (Electric), in a Non-myelinated Nerve Ending : Spatial Summation of (Properties of a Receptor Membrane), (Prof. Werner R. Loewenstein), 1724
Activity (Enzyme) : Metals and (Biochemical Society Symposium No. 15, Leeds, 1956), (organized and edited by E. M. Crook), *review* by Dr. O. T. G. Jones, 968
Activity (Enzyme), in the 'Isolated' Colon (Dr. B. F. Martin), 1464
Activity (Fibrinolytic) : Salt Concentration and (Dr. Monamy Buckell and Margaret Truscott), 1268
Activity (Fungicidal) : A Bacterium with (W. E. Crawley and D. C. Dodd), 63
Activity (Glutaminase), of the Foetal Membranes and Kidneys of Pigs (Ingeborg C. Radde and Prof. R. A. McCance), 115
Activity (Histolytic), in Seasonal Hypertrophy of the Reproductive Organs of *Hyla aurea* (Prof. L. R. Richardson), 480
Activity (Hypotensive or Sedative) : Reserpine Derivatives with Specific (A. Garattini, A. Mortari, A. Valsecchi and L. Valzelli), 1273
Activity (Immunological), of Precolostral Calf Serum (J. L. Turk), 838
Activity (Intestinal Proteinase): Neurosecretion and, in an Insect *Calliphora erythrocephala* Meig. (Ellen Thomsen and Ib Møller), 1401
Activity (Leucine Aminopeptidase), in Mast Cells (Dr. I. Braun-Falco and Dr. K. Salfeld), 51
Activity (Lipase and Alkaline Phosphatase) : Histochemical Demonstration of, in the Fat Body of the Desert Locust (J. C. George and J. Eapen), 268
Activity (Liver Hexokinase), in Rats adapted to Intermittent Starvation (Dr. R. Petrásek), 329
Activity (Magnetic) : Effect of, on Drifts of the *F*2 Region (Prof. B. Ramachandra Rao, E. Bhagiratha Rao and Y. V. Ramana Murty), 667
Activity (Mutagenic), of the Alkaloid Heliotrine in *Drosophila* (Dr. A. M. Clark), 731
Activity (Nervous) : Neuronal Dye-Sorption as a Histochemical Indicator of (Prof. Roland Fischer and Prof. Wolfgang Zeman), 1337
Activity (Pancreatic), of Guinea Pigs : Effect of β-Hydroxybutyrate Injections on the (Dr. H. D. Brahmachari and Mahendra Kumar), 51
Activity (Prolonged Muscular), without Phosphate Exchange (Prof. Jacob Sacks), 825
Activity (Reduced), of Histaminase in Rats sensitized by *Bordetella pertussis* (Makoto Niwa, Yutaka Yamadeya, Toshitaka Matsui and Prof. Yoshio Kuwajima), 755 ; (Toshitaka Matsui, Masayoshi Kishigami and Prof. Yoshio Kuwajima), 756
Activity (Serum Transaminase) : Changes in, following Myocardial Damage due to Lymphatic Congestion (M. Földi, Dr. P. Braun, Dr. M. Papp and Dr. I. Horváth), 1333
Activity (Succinic Dehydrogenase), in Brain Tissue of Rats after Ovariectomy and Steroid Administration (H. Sobel and B. Eckstein), 54
Activity (Synthetic), of Polynucleotide Phosphorylase from Sperm (Prof. Anwar A. Hakim), 334
Activity (Transaminase), in Dogs' Serum and Lymph after Hepatic Damage due to Acute Biliary Obstruction : Determination of (Dr. P. Braun, Dr. M. Papp and Dr. I. Horváth), 48
Activity and Behaviour in a Group of Small Animals : A Photographic Method for recording (Dr. D. K. Edwards), 625
Actomyosin : Proton Transfer and Super-contraction in (Dr. F. G. E. Pautard), 1391
Acute Alcoholic Intoxication : Triiodothyronine in (Dr. Henry Newman and Marion Edmonds Smith), 689
Acute Biliary Obstruction : Determination of Transaminase Activity in Dogs' Serum and Lymph after Hepatic Damage due to (Dr. P. Braun, Dr. M. Papp and Dr. I. Horváth), 48
Acute Insulin Deficiency : Production of, by Administration of Insulin Antiserum (P. H. Wright), 829
Acute Radiation Syndrome in the Plaice : Leucocytosis in Response to Bacteraemia as a Feature of the (A. Preston), 832
Ada, G. L., and Anderson, S. G. : Yield of Infective 'Ribonucleic Acid' from Impure Murray Valley Encephalitis Virus after Different Treatments, 799
Ada, G. L., and French, E. L. : Purification of Bacterial Neuraminidase (Receptor-destroying Enzyme), 1740
Adam, Dr. K. R., and Weiss, Dr. C. : Distribution of 5-Hydroxytryptamine in Scorpion Venoms, 1398
Adams, Dr. Roger : Elected a member of the Council of the United States National Academy of Sciences, 1575
Adams, W. N., and others : Smoke Emission of Low-Temperature Chars, 33
Adamson, A. W. (Spees, S. T., and) : Co-ordination Chemistry (Mechanisms of the Photochemical Reactions of Complex Ions), 1784
Adaptation of Marine Bacteria to Growth in Media lacking Sodium Chloride (Prof. D. B. Pratt and G. Waddell), 1208
Adaptation of a Photometer for the Direct Recording of Column Chromatograms (Prof. M. Verzele), 604
Adaptation (Molecular), in Haemoglobins—Nature of the Bohr Effect (Austen Riggs), 1037
Adaptive Formation of Tryptophan Peroxidase : Prevention of, by a Carcinogenic Azo Dye (Dr. Silvio Fiala and Anna A. Fiala), 1532
Adaptive Synthesis of Nitrate Reductase in Higher Plants (Dr. E. J. Hewitt and M. M. R. K. Afridi), 57
Addison, C. C., and Logan, N. : Co-ordination Chemistry (Properties of Volatile Nitrato–Iron Complexes), 1785
Adélie Penguin : The, *Pygoscelis adeliae* (Hombron and Jacquinot), (Dr. William J. L. Sladen), 23
Adenosine Diphosphate : Interaction of Magnesium and, in Photosynthetic Phosphorylation (J. B. Mudd), 900
Adenovirus Antigens : Study of, by Immunoelectrophoresis (Dr. H. G. Pereira, Dr. A. C. Allison and Dr. C. P. Farthing), 895
Adenylosuccinic Acid : Synthesis of, in Preparations of Mammalian Skeletal Muscle (C. L. Davey), 995
Adhesion and Ion-Exchange between Mica Surfaces (George L. Gaines, jun.), 1109
Adjuvants (Growth), in Culture : Morphogenetic Response of *Citrus* Ovules to (N. S. Ranga Swamy), 735
Administered Vitamin B_{12} (Orally) : Effect of D-Sorbitol on the Absorption of (Dr. J. N. Marshall Chalmers and N. K. Shinton), 120
Administration of Insulin Antiserum : Production of Acute Insulin Deficiency by (P. H. Wright), 829
Administration (*in vivo*) of 5-Iododeoxyuridine labelled with Iodine-131 : Incorporation of 5-Iodouracil labelled with Iodine-131 into the Deoxyribonucleic Acid of Human Leukaemic Leucocytes following (Dr. M. L. Eidinoff, L. Cheong, E. Gambetta Gurpide, R. S. Benua and R. R. Ellison), 1686
Administration (Oral) : Presence of Griseofulvin in Hair of Guinea Pigs after (J. C. Gentles, M. J. Barnes and K. H. Fantes), 256
Administrative Medicine—Transactions of the Fifth Conference, Princeton, 1956 (edited by George S. Stevenson), *review* by Dr. G. A. Clark, 639
Admission of Students to Universities, 1723
Adrenal Cortical Function in the Pregnant Sheep (Kathleen W. Robinson), 690
Adrenal Gland of Young Calves : Changes in the Secretion of 20α-Hydroxypregn-4-en-3-one by the (Dr. W. E. Balfour, Dr. R. S. Comline and R. V. Short), 467
Adrenal Glomerulosa : Stress Activation of (Dr. M. Hill, K. Dvořák and M. Pospíšil), 1819
Adrenal 17-Hydroxycorticosteroid Secretion in the Dog : Effect of Morphine upon the (Prof. Tatuzi Suzuki, Kazukuni Yamashita, Seiichi Zinnouchi and Takaaki Mitamura), 825
Adrenal Medulla : Deoxyribonucleic Acid Content of the Cell-Nuclei in the, after Exposure to Low Temperatures (L. Leeman), 1188
Adrenaline : Condensation Products of Ethylenediamine with (Dr. Kunio Yagi and Dr. Toshiharu Nagatsu), 822
  Rumination in Sheep caused by Injection of (R. N. B. Kay), 552
Adrian, Rt. Hon. Lord : The Place of Science in Universities Past and Present, 1706

Adsorption and Desorption of Moisture in Fired Ceramic Materials (F. Vaughan and A. Dinsdale), 600
Adult Education : Developments in, *review* by T. H. Hawkins, 1419
Adult Education (English) : Trends in (edited by Prof. S. G. Raybould), *review* by T. H. Hawkins, 1419
Adult Human Haemoglobin : Comparison of Normal, with Haemoglobin I by 'Fingerprinting' (Constituents of Human Haemoglobin), (Makio Murayama and Dr. V. M. Ingram), 1798
Adult Mosquitoes : Galeal Structure in (Gordon Surtees), 971
Adult Rabbits : Serum Antibody and γ-Globulin in Baby Rabbits after Transfer of Ribonucleoprotein from (Dr. Miroslava Hrubešova, Dr. Brigitte A. Askonas and Dr. J. H. Humphrey), 97
Adult and Foetal Human Haemoglobins : Identity of the α-Chains of (J. A. Hunt), 1373
Adults (Male and Female), of *Trogoderma granarium* Everts : Differential Response of, towards Sterilizing Doses of Gamma-radiation (G. C. Carney), 338
Advance Detonation in a Tubular Charge of Explosive (Dr. D. W. Woodhead), 1756
Advanced European Research (Council of Europe Competition in), 509
Advanced Gas-cooled Reactor Power Stations, 508
Advanced Study in Science (NATO support for Institutes for), 509
Advancement (Educational), and the Under-developed Countries, 633
Advances in Clinical Chemistry (edited by Dr. Harry Sobotka and Dr. C. P. Stewart), Vol. I, *review* by Prof. J. N. Davidson, 5
Advances in Enzymology : Further, *review* by Dr. Edwin C. Webb, 961
Advances in Enzymology and related Subjects of Biochemistry (edited by F. F. Nord), Vol. 20, *review* by Dr. Edwin C. Webb, 961
Advances in Food Research (edited by E. M. Mrak and G. F. Stewart), Vol. 8, *review* by Dr. Magnus Pyke, 351
Advances in Microbiology, *review*, 1219
Advances in Protein Chemistry (edited by C. B. Anfinsen, Jr., M. L. Anson, Kenneth Bailey and John T. Edsall), Vol. 12, *review* by Dr. M. F. Perutz, 1290
Advances in Protein Chemistry : Recent (Department of Chemistry, Biology and Geology of the Kingston Technical College Postgraduate Lecture Course on), 86
Advances in Veterinary Science (edited by C. A. Brandly and E. L. Jungherr), Vol. 4, *review* by Prof. H. Burrow, 1555
Advances in Virus Research (edited by Kenneth M. Smith and Max A. Lauffer), Vol. 5, *review* by Prof. F. C. Bawden, 636
Adventitious Roots (Seminal and) : A Method of Growing Grass Plants with Separation of (R. Dorrington Williams), 415
Advisory Committee on Defence Science, Commonwealth—Meeting in in Australia (Sir Leslie Martin), 1165
Advisory Council on Scientific Policy : Eleventh Annual Report (1957-58), 67
Advisory Water Committee, Central : Fourth Meeting, 152
  Appointment of Prof. J. Proudman as chairman of the Sub-Committee on the Demand for Water, 152
Aerobacter aerogenes : Aerobic Fermentation of Whey by a Nitrogen-fixing Strain of (Prof. D. B. Johnstone and M. Pfeffer), 992
Aerobic Fermentation of Whey by a Nitrogen-fixing Strain of *Aerobacter aerogenes* (Prof. D. B. Johnstone and M. Pfeffer), 992
Aeronautical Establishment, National : Formation of, as a new Division of the National Research Council of Canada, 291
  Appointment of Frank R. Thurston as acting director, 291
Aeronautical Sciences, American Institute of : Election of Sir George R. Edwards as an Honorary Fellow, 368
  Election of Dr. A. M. Ballantyne as a Fellow, 368
Aeronautical Society, Royal : Honorary Companionship conferred on Gustavus Green, 154
  Gold Medal awarded to Marcel Dassault, 794
  Discussion on Hypersonic Flow, 1095
  Lecture Theatre for the, 1569
  Honorary Fellowship conferred on Prof. J. Ackeret, Sir William S. Farren and S. B. Gates, 1648
  Honorary Companionship conferred on E. C. Bowyer and Sir William Hildred, 1648
  Silver Medal awarded to Dr. E. A. Watson, 1648
  Bronze Medal awarded to D. G. King-Hele, 1648
  British Gold Medal for Aeronautics awarded to R. S. Stafford, 1648
  British Silver Medal for Aeronautics awarded to D. J. Farrar and Dr. N. H. Searby, 1648
  Wakefield Gold Medal awarded to K. A. Wood, 1648
  R. P. Alston Medal awarded to A. W. Bedford, 1648
  N. E. Rowe Medal awarded to J. Dunham, 1648
  Simms Gold Medal awarded to R. P. Probert, 1648
  George Taylor (of Australia) Gold Medal awarded to H. L. Cox, 1648
  Edward Busk Memorial Prize awarded to T. R. F. Nonweiler, 1648
  Orville Wright Prize awarded to D. A. Spence, 1649
  Herbert Ackroyd Stuart Memorial Prize awarded to A. A. Lombard, 1649
  J. E. Hodgson Prize awarded to J. E. Allen, 1649
  Branch Prize awarded to B. D. Blackwell, 1649
  Navigation Prize awarded to C. M. Cade, 1649
  Usborne Memorial Prize awarded to Dr. J. S. Przemieniecki, 1649
  Pilcher Memorial Prize awarded to A. W. Kitchenside, 1649
Affinities : Atomic Electron (H. R. Johnson and Dr. F. Rohrlich), 244
Affinity (Electron), of Atomic Lithium (E. Holøien), 173
Affinity (Electron), of Oxygen (B. A. Tozer), 1389
Affonso, Ottilia R. (Mitidieri, Emilio, and) : Effect of Salicylate on Blood and Liver Xanthine Dehydrogenase of Rats, 471
Africa South of the Sahara, Commission for Technical Co-operation in (Food and Agriculture Organization of the United Nations and the) : Technical Meeting on Legumes in Agriculture and Human Nutrition, 439
Africa South of the Sahara, Scientific Council for : Publication No. 32, Ninth Meeting of the Scientific Council, Accra (1958), 585
Africa (Central) : Scientific Research in, 1718
Africa (East) : A Study of the Aphididae (Homoptera) of (V. F. Eastop), *review* by Dr. W. J. Hall, 208
Africa (East) High Commission : Annual Report for 1958, 1781
  Annual Report for 1957-1958 of the East African Industrial Research Organization, 1789
Africa (South) : Academic Freedom and the Universities of, 1551
Africa (West) : Flora of, *review* by A. W. Exell, 6
  A Third Species of 'Pepper' in (J. Yanney Wilson), 1142
Africa (West Tropical) : Flora of (Dr. J. Hutchinson and Dr. J. M. Dalziel), second edition revised by R. W. J. Keay, *review* by A. W. Exell, 6
Africa and England: Precambrian Coelenterata from Australia, (Dr. M. F. Glaessner), 1472
African Agriculture : Legumes in (Dr. R. O. Whyte and T. R. G. Moir), 439
African Aphids, *review* by Dr. W. J. Hall, 208
African Segmentary Systems : Tribes without Rulers—Studies in (edited by John Middleton and the late David Tait), *review* by Prof. M. Fortes, 1006
African (British East) Waters : Marlins in (F. Williams), 762
African (East) Industrial Research Organization : Annual Report for 1957-1958 (East Africa High Commission), 1789
African (South) Council for Scientific and Industrial Research (Dr. S. M. Naudé), 853
African (South) Council for Scientific and Industrial Research : Register of Current Scientific Research at South African Universities (1957), 366
  Report of the Symposium on Design for Tropical Living (prepared by the National Building Research Institute), 1022
African (South) Museum : Report for 1957-58, 1570
African (South) Stone Age Cultures : Some (Dr. R. J. Mason), 377
African (South) Universities: Register of Current Scientific Research at, 1957 (South African Council for Scientific and Industrial Research), 366
Afridi, M. M. R. K. (Hewitt, Dr. E. J., and) : Adaptive Synthesis of Nitrate Reductase in Higher Plants, 57
Afrique Centrale, Institut pour le Recherche Scientifiques en : Annual Report for 1956, 1718
After-Effects : Figural (Dr. Peter McEwen), 1027
Agar (Kligler's Iron) : The Phenylalanine Test on, for the Identification of *Proteus* (D. J. Stewart), 1537
Agar Diffusion Plates : Photographic Recording of (J. R. Hunter), 1283
AGARD : AGARDograph No. 29, Polar Atmosphere Symposium, Oslo, 1956, Part 1, Meteorology Section (edited by R. C. Sutcliffe) ; Part 2, Ionospheric Section (edited by K. Weekes), *review* by James Paton, 279
  Joint Meeting of the Aeromedical and Flight Test Techniques and Instrumentation Panels, 652
  AGARDograph No. 25 : Aviation Medicine—Selected Reviews (edited by Clayton S. White, W. Randolph Lovelace, II, and Frederic G. Hirsch), *review*, 1291
Agaricus campestris L. ex Fr. : Spore Germination in (Dr. D. M. McTeague, Dr. S. A. Hutchinson and Dr. R. I. Reed), 1736
Age : Variation of Sensitivity to Ionizing Radiation with (M. L. Crosfill, Patricia J. Lindop and Prof. J. Rotblat), 1729
Age of the Earliest Remains of Man, 1433
Age of Plants : Amino-Acid Composition of the Proteins of Barley Leaves in relation to the Mineral Nutrition and (Dr. B. P. Pleshkov and Dr. L. Fowden), 1445
Age of Science : Education in the, 1436
Age and Sex : Water and Electrolyte Metabolism in relation to Age (Ciba Foundation Colloquia on Ageing, Vol. 4), (edited by G. E. W. Wolstenholme and Maeve O'Connor), *review* by Prof. P. L. Krohn, *777*
Age (Boreal) : A Marine Transgression of, in the Southernmost Part of Norway (Gunnary Gabrielsen), 1616
Age (Bronze) : Life and Death in the (Sir Cyril Fox), *review* by M. C. Burkitt, 1486
Age (Known) : Radiocarbon Measurements on Samples of (W. S. Broecker, Edwin A. Olson and Junius Bird), 1582
Ageing : Ciba Colloquia on, Vol. 4, Water and Electrolyte Metabolism in relation to Age and Sex (edited by G. E. W. Wolstenholme and Maeve O'Connor), *review* by Prof. P. L. Krohn, *777*
Ageing of Human Cartilage (David Kaplan and Dr. Karl Meyer), 1267
Ageing Periosteum : Changes in the Osteoblastic and Mitochondrial Population of (Dr. E. A. Tonna and Dr. N. Pillsbury), 337
Ageing Process in the Ovary : Influence of the Anterior Pituitary on the (Dr. E. C. Jones and Prof. P. L. Krohn), 1155
Ageing Rats : Sex Incidence of Vascular Lesions in, in relation to Previous Pregnancies (Prof. Theodore Gillman and Michael Hathorn), 1139
Agent (Protective), against Osmotic Lysis : Spermine as a (J. Mager), 1827
Agents : Effects of 2:4-Dinitrophenol and other, on the Swelling of Isolated Mitochondria (Dr. J. B. Chappell and Dr. G. D. Greville), 1737
Agents (Physical) : Method for Testing the Influence of Drugs and, upon Mitosis (Prof. Elio Guido Rondanelli, Pasquale Gorini and Demenico Pecorari), 190
Ager, Dr. J. A. M., and others: New Variant of Human Foetal Haemoglobin, 31
Ages: Frequency of Meteorite Falls throughout the (Prof. Hans Pettersson), 1114 ; (Dr. J. F. Lovering), 1664
Ages (Cosmic-Ray Exposure), of Meteorites : Calculation of Erosion in Space from the (Dr. F. L. Whipple and Dr. E. L. Fireman), 1315
Aggregation of Cod Myosin during Frozen Storage (J. J. Connell), 664
Agnostids : General Caeca of (A. A. Öpik), 1750
Agranoff, Dr. B. W., and Fox, M. R. Spivey : Antagonism of Choline and Inositol, 1259
Agricultural Advisory Service, National ; Retirement of Sir Robert Rae from the directorship, 1160
  Appointment of J. A. McMillan as director, 1160
  Appointment of W. E. Jones as senior education and advisory officer, 1160
  Appointment of H. E. Evans as director of the National Agricultural Advisory Service in Wales, 1160
Agricultural Aviation, Vol. I, No. I (European Agricultural Aviation Centre), 720
Agricultural Geography : Ecology and Economics of, *review* by Prof. A. N. Duckham, 423
Agricultural History Society (British), and the Economic History Society : Joint Conference on Agriculture and Rural Life, 582
Agricultural Research : Studentships and Fellowships in (Agricultural Research Council), 722
Agricultural Research Council : Grant of £1,492 to the Department of Veterinary Medicine in the University of Bristol, for research on experimental transmissions of lymphoid leukosis, 581

  Grant of £1,172 to the Department of Physiology in the University of Bristol, for research on bovine acetonaemia, 581
  Studentships and Fellowships in 1959, 722
  To take over the Ditton Laboratory, the Low Temperature Research Station and the Pest Infestation Laboratory of the Department of Scientific and Industrial Research, 862
  Investigation into the Quality of Protein Feeding-Stuffs, 1303
Agricultural Research Institute, Indian (Dr. B. P. Pal), 371
Agricultural University, Wageningen (under the auspices of the Comité Européen de Zoologie Agricole and the) : Proceedings of a Symposium on Insect and Food-plant (Wageningen, 1957), *review* by Dr. C. J. Banks, 1767
Agricultural and Horticultural Research Station (the National Fruit and Cider Institute), Long Ashton, Bristol : Annual Report for 1957, with Index 1953-57, 1507
Agriculture at Aberdeen, 862
Agriculture : American (Prof. Edward Higbee), *review* by Prof. A. N. Duckham, 423
  Inorganic Micronutrients in Physiology and, *review* by Dr. E. J. Hewitt, 1009
Agriculture, Canadian Department of : Ninth International Botanical Congress, 1502
Agriculture (African) : Legumes in (Dr. R. O. Whyte and T. R. G. Moir), 439
Agriculture (Tropical) : An Introduction to (Sir Harold Tempany and D. H. Grist), *review* by Prof. J. W. Purseglove, 966
Agriculture, Fisheries and Food, Ministry of : Fishery Investigations, Ser. 2, Vol. 22, No. 4, Feeding of the Oystercatcher (*Haematopus ostralegus*) on the Edible Mussel (*Mytilus edulis*) in the Estuary of the River Conway (R. E. Drinnan), 153
  Appointment of Prof. A. N. Duckham as chairman of the Milk and Milk Products Technical Advisory Committee, 368
  Fishery Investigations, Ser. 2, Vol. 21, No. 8, An Account of the Fishing Gear of England and Wales (the late F. M. Davis), revised edition, 1023
  Fishery Investigations, Ser. 2, Vol. 21, No. 6, The Bear Island Cod—Migrations and Movements (G. C. Trout), 1100
  Appointment of Dr. H. A. Cole as director of fisheries research, 1567
  Appointment of R. J. H. Beverton as deputy director of fisheries research, 1568
Agriculture, Fisheries and Food, Ministry of, and the Scottish Home Department (Development Commissioners, in association with the) : Postgraduate Training Grants in Fishery Research, 1094
Agriculture and Human Nutrition : Legumes in (Food and Agriculture Organization of the United Nations and the Commission for Technical Co-operation in Africa South of the Sahara Technical Meeting on), 439
Agriculture and Rural Life (British Agricultural History Society and the Economic History Society Joint Conference on), 582
Aharoni, Yohanan, and others : Hazor I, an Account of the First Season of Excavations, 1955 (The James A. De Rothschild Expedition at Hazor), *review* by Peter J. Parr, 951
Ahmed, A. K. Shamsuddin, and Wilkins, R. G. : Co-ordination Chemistry (Kinetics of the Dissociation of Complex Cyanides and of Ethylene—Diamine Nickel Complexes), 1784
Ahrenfeldt, Dr. Robert H. : Psychiatry in the British Army in the Second World War, *review* by Dr. D. Russell Davis, 208
Ahuja, L. D. : The Nature of Coal (Conversion of Non-coking Coal to Coking Coal by Partial Hydrogenation), 1438
Aimen, R. A. (Bhide, Dr. N. K., and) : Pharmacology of a Tranquillizing Principle in *Paspalum scrobiculatum* Grain, 1735
Aims of Education (A. N. Whitehead), 1437
Air : Effect of Humidity on the Breakdown of a 1-cm. Homogeneous Field Spark Gap in (Dr. K. Phillips, K. R. Allen and A. Refsum), 532
Air (Humid) : Secondary Ionization in (Prof. J. M. Meek), 1805
Air Force, United States Department of the (sponsored by the) : Guided Missiles—Operations, Design and Theory, *review*, 210
Air Force Cambridge Research Center (United States) : Conference on Silicon Carbide, 722
Air Force Office of Scientific Research : Grant of 38,415 dollars to Prof. G. A. Jeffrey (University of Pittsburgh), to initiate research on the structure of crystalline hydrates of organic molecules and ions, 86
Air Force Office of Scientific Research, and others : International Seminar on the Atomic Mechanisms of Fracture, 154
Air Ions (Negative) : An Ezymatic Basis for the Acceleration of Ciliary Activity by (Prof. A. P. Krueger and Richard F. Smith), 1332
Air Ministry (Meteorological Office) : Geophysical Memoir No. 101, Upper Air Temperature over the World (N. Goldie, J. G. Moore and E. E. Austin), 864
Air Pollution Control Association : Annual Meeting, 722
Air Shower Particles : Multiple Geiger Counter Telescope Measurements of the Directions of (Dr. H. D. Rathgeber), 386
Air Showers : Extensive (Dr. William Galbraith), *review* by Dr. R. M. Tennent, 1555
Air Temperature Record : World Low, 153
Air Temperature (Upper) over the World (N. Goldie, J. G. Moore and E. E. Austin), 864
Airborne Bacteria : Chloramphenicol and Survival of (S. J. Webb), 1072
Airborne Droplets : Detecting Volatile (K. R. May), 742
Airborne Radar at the Royal Radar Establishment, 647
Aircraft : Navigational Aids for, 1019
Aircraft (Historic) : Register of, 580
Aircraft (Low-flying) : Drift of Toxic Chemicals released from a (D. Yeo, N. B. Akesson and H. H. Coutts), 131
Aircraft Establishment, Royal : Appointment of S. F. Follett as deputy director (equipment), 931
  Appointment of Dr. A. G. Touch as senior superintendent of the Radio Department, 931
  Appointment of R. J. Lees as head of the Instrument and Photographic Department, 931
  Table of Artificial Earth Satellites, 1566
Airglow (Twilight), in the Northern Hemisphere : Observations of the Lithium Lines in the (Prof. A. Vallance Jones), 1315
Airglow at 6708 A. (New Twilight) : Origin of Upper-Atmosphere Lithium Atoms responsible for the (D. R. Barber), 384
Aked, A., and others : Gas Discharges (Spark, High-frequency and Glow Discharges), 93
Akesson, N.B., and others : Drift of Toxic Chemicals released from a Low-flying Aircraft, 131
Alaska : Urinary Excretion of β-Amino-isobutyric Acid in Eskimo and Indian Populations of (Dr. A. C. Allison, Dr. B. S. Blumberg and Dr. S. M. Gartler), 118
Albasiny, E. L. : The Preparation of Programs for an Electronic Digital Computer, *review*, 969
Albers, Dr. Wayne, and others : Effects of Pyridoxine Withdrawal on Cerebral Circulation and Metabolism in a Pyridoxine-dependent Child, 751
Albertsson, Dr. P. Å. (Frick, Dr. G., and) : Bacteriophage Enrichment in a Liquid Two-Phase System with Subsequent Treatment with 'Freon' 113, 1070
Albino Citrus Seedlings : Inducing Chlorophyll Formation in (Dr. Faisal A. Minessy), 553
Albino Specimen of the Common Frog (G. E. Williams), 1408
Albino and Pigmented Mice receiving Furocoumarins—Psoralen and 8-Methoxypsoralen : Ultra-violet Carcinogenesis in (M. A. Pathak, Prof. F. Daniels, jun., C. E. Hopkins and T. B. Fitzpatrick), 728
Albrecht, K. (Wix, Dr. G., and) : A New Method for the Microbiological Oxidation of Steroids, 1279
Albugo candida : Oospore Germination in (T. C. Vanterpool), 1718
Albumin labelled with Iodine-131 in an Analbuminaemic Subject (T. Freeman, C. M. E. Matthews, Dr. A. S. McFarlane, H. Bennhold and E. Kallee), 606
Albumin in the Plasma of Thyrotoxic Patients : An Iodine Compound associated with (Christina Cameron and K. Fletcher), 116
Albumin (Human), labelled with Iodine-131 : Chromatographic Behaviour of (Dr. S. Cohen), 393
Albumin (Serum), during Short-term Action of Pepsin at Room Temperature : Splitting of the Electrophoretic Pattern of (E. Annau), 190
Alcohol : Utilization of, in Germinating Pea Seedlings (E. A. Cossins and Dr. E. R. Turner), 1599
Alcohol (Allyl), as a Nutrient for Micro-organisms (H. L. Jensen), 903
Alcohol (Cyclic Allylic) : Effect of Alkali Salts on the Steric Course of Hydrogenation of a (M. C. Dart and Prof. H. B. Henbest), 817
Alcoholic Intoxication (Acute) : Triiodothyronine in (Dr. Henry Newman and Marion Edmonds Smith), 689
Alcohols : Effect of Low Concentrations of, on the Interfacial Tension between Water and Hydrocarbons (F. Franks and Dr. D. J. G. Ives), 316
Alderson, R. H. (Wroe, H., and) : An Effect of Oxide Layers on the Behaviour of Vacuum Arc Cathode Spots, 1544
Aldosaccharides in Body Fluids : Rapid Specific Method for Determination of (Dr. Eric Hultman), 108
2-Aldoxime (Pyridine) : Ferrous and Ferric Complexes with (Dr. G. I. H. Hanania and Dr. D. H. Irvine), 40
Alexander, J. B. : Geology and Palaeontology in Malaya—Pre-Tertiary Stratigraphic Succession in Malaya, 230
Alexander, Dr. K. M. : Errors caused by Partial Drying of Hardened Portland Cement during Testing, 885
Alfvén Waves in a Gas Discharge (D. F. Jephcott), 1652
Alga (Marine Red), requiring Vitamin B_{12} : *Goniotrichum elegans*, a (Lisbeth Fries), 558
Algal Species (Epiphytic), and their Macrophytic Hosts : Relationship between (G. A. Prowse), 1204
Alicyclic Structures in Coals (S. Ergun and V. H. Tiensuu), 1668
Alicyclicity and Smoke Emission of Coal (B. K. Mazumdar, S. S. Choudhury and A. Lahiri), 1613
Alimen, H., et autres : Archives de l'Institut de Paléontologie Humaine, Mémoire 29, La Grotte de Fontéchevade, Troisiéme partie, Géologie et Paléontologie, 1369
Aliphatic Fluorine Compounds (A. M. Lovelace, Douglas A. Rausch and William Postelnek), *review* by Prof. R. N. Haszeldine, 139
Alivisatos, Prof. Spyridon G. A. : Mechanism of Action of Diphosphopyridine Nucleotidases, 1034
Alkali Cations : Absorption of, by Plant Tissue Cultures (Dr. J. F. Sutcliffe and E. R. Counter), 1513
Alkali Concentration (Low) : Catalytic Action of Copper in the Alkaline Autoxidation of Cellulose at (R.I.C. Michie and Dr. S. M. Neale), 534
Alkali Fluorides : Bond Energies of some (Dr. F. M. Page and Dr. T. M. Sugden), 1672
Alkali Salts : Effect of, on the Steric Course of Hydrogenation of a Cyclic Allylic Alcohol (M. C. Dart and Prof. H. B. Henbest), 817
Alkaline Autoxidation of Cellulose at Low Alkali Concentration : Catalytic Action of Copper in the (R. I. C. Michie and Dr. S. M. Neale), 534
Alkaline Phosphatase : Distribution of, in the Arteries of several Species (Dr. Manuel René Malinow, Martha A. Fernandez, Alvaro L. Gimeno and Grato E. Bur), 1262
Alkaline Phosphatase Activity (Lipase and) ; Histochemical Demonstration of, in the Fat Body of the Desert Locust (J. C. George and J. Eapen), 268
Alkaline Phosphomonoesterase in *Escherichia coli* : A Possible Negative Feedback Phenomenon controlling Formation of (T. Horiuchi, S. Horiuchi, and D. Mizuno), 1529
Alkaloid Heliotrine in *Drosophila* : Mutagenic Activity of the (Dr. A. M. Clark), 731
Alkaloids (Pyrrolizidine) : Action of, on the Neuro-Muscular Junction (Dr. C. H. Gallagher and Dr. J. H. Koch), 1124
Alkyl N-(*bis*-(ethylenimido)phosophoro)-carbamates, a New Series of Anti-Tumour Agents : 'Dual Antagonists'—(Thomas J. Bardos, Zinon B. Paranastassiou, Albert Segaloff and Julian L. Ambrus), 399
Alkyl-Aryl Sodium Sulphonates as Standard Substances in Detergent Chemistry : Some (E. Q. Laws and W. Hancock), 1473
All : Secondary Education for—a New Drive (White Paper on), 511
All-India Congress of Zoology : First (Zoological Society of India), 1304
Allan, D. : Appointed lecturer in applied veterinary pathology at the University of Liverpool, 581
Allard Lake Ilmenites : Remanent Magnetism of the (Charles M. Carmichael), 1239
Allchin, Dr. F. R. : Morhana Parar, 437
  An Indian History of Science, *review*, 1353
Allen, Dr. Ann, and Alston, Dr. R. E. : Formation of Purple Pigment in *Spirogyra pratensis* Cultures, 1064

Allen, Prof. A. J. : Awarded a grant of 129,000 dollars by the Office of Naval Research, to continue research on precision scattering of nuclear particles, 86
Allen, Dr. Clifford : Social Class and Mental Illness, *review*, 354
Allen, Frank W., and others (edited by): Annual Review of Biochemistry, Vol. 27, *review* by Prof. F. G. Young, 961
Allen, Dr. G. : Relaxation Processes (Measurements on Mechanical Relaxation of Rubber), 584
Allen, Prof. Jack : *Obituary* of Prof. A. H. Gibson, 859
Allen, J. E. : Awarded the J. E. Hodgson Prize of the Royal Aeronautical Society, 1649
Allen, Prof. James S. : The Neutrino, *review* by Prof. H. W. B. Skinner, 1421
Allen, K. R., and Phillips, Dr. K. : Effect of Humidity on the Spark Breakdown Voltage, 174
  Effect of Radiation on the Breakdown of Homogeneous Field and Sphere Gaps, 233
Allen, K. R., and others : Effect of Humidity on the Breakdown of a 1-cm. Homogeneous Field Spark Gap in Air, 532
Allen, Dr. N. L., and Payne, Dr. R. M. : Gas Discharges (Operation of SCEPTRE III in the Laboratories of Associated Electrical Industries), 92
Allergic Disorders : Immunological Aspects of (British Society for Immunology and the British Association of Allergists Symposium on), 296
Allergists, British Association of (British Society for Immunology and the) : Symposium on the Immunological Aspects of Allergic Disorders, 296
Allibone, Dr. T. E. : Fusion of Heavy Hydrogen, 569
Allison, Dr. A. C. : Genetic Control of Human Haptoglobin Synthesis, 1312
Allison, Dr. A. C., and Humphrey, Dr. J. H. : Estimation of the Size of Antigens by Gel Diffusion Methods, 1590
Allison, Dr. A. C., and others : Urinary Excretion of β-Amino-*iso*butyric Acid in Eskimo and Indian Populations of Alaska, 118
  Study of Adenovirus Antigens by Immunoelectrophoresis, 895
Alloxanized Rats (Normal and) : Action of Nicotinamide on Acetoacetate Metabolism of Liver Homogenates of (S. Eser, S. Tekman and A. Araz), 184
Alloys : Precipitation in (X-Ray Diffraction and Electron Microscopy Groups of the Institute of Physics Conference on), 796
Alloys (Aluminium–Zinc) : Crystallographic Orientation of Nodules formed by the Grain Boundary Reaction of (Dr. Ryoji Watanabe and Dr. Shigeyasu Koda), 1667
Alloys (Chromium–Iron and Chromium–Manganese) : Low-temperature Specific Heats of Body-centred Cubic (C. T. Wei, C. H. Cheng and Prof. P. A. Beck), 315
Alloys (Ternary Aluminium–Zinc–Magnesium) : Fatigue Properties of (I. J. Polmear), 1388
Allport, Noel L., and Keyser, Dr. J. W. : Colorimetric Analysis, Vol. I, Determinations of Clinical and Biochemical Significance, second edition, *review* by Dr. N. R. Lawrie, 207
Allsopp, Dr. A. (Mitra, Dr. G. C., and) : Effects of Kinetin, Gibberellic Acid and certain Auxins on the Development of Shoot Buds on the Protonema of *Pohlia nutans*, 974
Allt Rhyd-y-groes Nature Reserve (Nature Conservancy), 1650
Allyl Alcohol as a Nutrient for Micro-organisms (H. L. Jensen), 903
Allylic Alcohol (Cyclic) : Effect of Alkali Salts on the Steric Course of Hydrogenation of a (M. C. Dart and Prof. H. B. Henbest), 817
Alper, Tikvah (Gillies, Dr. N. E., and) : Reduction in the Lethal Effects of Radiations on *Escherichia coli B* by Treatment with Chloramphenicol, 237
α-Chains of Adult and Foetal Human Haemoglobins : Identity of the (J. A. Hunt), 1373
α-Globulin Fraction in Human Serum : Prealbumin as a Complex in the (Dr. J. R. Tata), 877
α-Glycerophosphate Dehydrogenase : Anion Inhibition of (Dr. Otto Z. Sellinger and Dr. O. Neal Miller), 889
α-Helices and a New Polypeptide Fold in Poly-β-Benzyl-L-Aspartate (E. M. Bradbury, L. Brown, A. R. Downie, Dr. A. Elliott, W. E. Hanby and T. R. R. McDonald), 1736
α-Keratin : Structure of (Dr. R. D. B. Fraser, T. P. Macrae and Dr. G. E. Rogers), 592
α-Tocopherol and Hyaluronidase *in vivo* (Mrs. Elizabeth A. Irving), 398
α-, β-, γ- and δ-Tocopherols (Pure), in the Growing Chick : Relative Rates of Liver Storage of (T. W. Griffiths), 1061
Alsop, L. E., and others : Maser Observations in Radio Astronomy, 223
Alstead, Dr. S. : Elected a Fellow of the Royal Society of Edinburgh, 719
Alston, Dr. R. E. (Allen, Dr. Ann, and) : Formation of Purple Pigment in *Spirogyra pratensis* Cultures, 1064
Alston (R. P.) Medal of the Royal Aeronautical Society awarded to A. W. Bedford, 1648
Alt, J. : Antarctic Meteorology, 1504
Altenburg, Edgar (Altenburg, L. S., and) : Ratio of Visible to Lethal Mutations produced in *Drosophila* by Phenylalanine Mustard, 699
Altenburg, L. S., and Altenburg, Edgar : Ratio of Visible to Lethal Mutations produced in *Drosophila* by Phenylalanine Mustard, 699
Alteration in the Excretion of Free Serine in Urine from Irradiated Humans (Dr. Arthur L. Kretchmar), 1809
Alterations (Geotropic and Morphological), in Rice Seedlings caused by Plant Growth Regulators (E. H. Roberts), 1197
Alternating-Current Voltammetry (Cyclic), with a Platinum Electrode (André L. Juliard), 1040
Alternsforschung : Experimentelle—Symposium der Europäischen Abteilung des Biologischen und Medizinischen Forschungskomitees der Internationalen Gerontologischen Gesellschaft, Basel, 1956 (herausgegeben von F. Verzár), *review* by Prof. P. L. Krohn, 777
Altitude (50 km.) : Observations of Intense Ionization of Long Duration below, after some Strong Solar Flares (Dr. Bengt Hultqvist and Johannes Ortner), 1179
Altitude (High-) Explosions : Geophysical Effects associated with (Dr. P. J. Kellogg, Prof. E. P. Ney and Prof. J. R. Winckler), 358
Altitude (High-) Geophysical Experiments : Argus (Dr. Alan T. Waterman and Dr. Detlev W. Bronk), 1019
Altitude (High-) Nuclear Explosions : Geophysical Effects of (T. Obayashi, S. C. Coroniti and E. T. Pierce), 1476
Altschul, Aaron M. (edited by) : Processed Plant Protein Foodstuffs, *review* by Dr. Magnus Pyke, 351
Altschul, Lucille (Cohen, Prof. Saul G., and) : Asymmetric Hydrolysis of Diethyl Acetamidomalonate by Chymotrypsin, 1678
Altschul, Prof. Rudolf : *Obituary* of Prof. Alfred Kohn, 1229
Altszuler, N., and others : Mechanism of Action of Insulin, 1123
Alumina : Polymorphic Conversion of Mercuric Iodide on (Prof. Harry Zeitlin and Harry Goya), 1041
γ-Alumina (Anhydrous) : Evidence for a Variable Long-range Order in nearly (Prof. G. W. Brindley and Dr. M. Nakahira), 1620
Aluminium Hydroxides derived from Proton Magnetic Resonance : Positions of Protons in (Structures of some Hydroxides and Hydrous Oxides), (D. J. Kroon and C. v. d. Stolpe), 944
Aluminium Laboratories, Ltd. : Appointment of Dr. Robert T. Parker as head of the Banbury and Geneva offices, 1502
Aluminium Oxide Anodic Films : Sealing of (Dr. R. M. Hinde, E. A. Kellett and P. H. Harris), 39
γ-Aluminium Oxide/Platinum : Structure and Mode of Action of the Contact (Prof. Alfons Krause), 1615
AlO Spectrum : Hollow-Cathode Emission of the (V. Wilson Goodlett and K. Keith Innes), 243
Aluminium–Zinc Alloys : Crystallographic Orientation of Nodules formed by the Grain Boundary Reaction of (Dr. Ryoji Watanabe and Dr. Shigeyasu Koda), 1667
Aluminium–Zinc–Magnesium Alloys (Ternary): Fatigue Properties of (I. J. Polmear), 1388
Aly, Raga H. (Gabr, Dr. Yousry, and) : Slow Contraction of Smooth Muscle produced by Human Plasma, 897
Amarose, A. P. : Some Effects of Colchicine on Lampbrush Chromosomes, 975
Ambrus, Julian L., and others : 'Dual Antagonists' ; Alkyl N-(*bis*-(ethylenimido) phosphoro)-carbamates ; a New Series of Anti-Tumour Agents, 399
  Anti-Tumour Activity of 5-Mercaptouracil, 612
Ameen, A., and Shafiq, Dr. S. A. : Proepithelial Regeneration in the Midgut of Beetles, 913
America : John and William Bartram's (edited by Helen Gere Cruickshank), *review* by Dr. L. Harrison Matthews, 1006
America North of Mexico : The Spider Family Dictynidae in (Prof. Ralph V. Chamberlin and Willis J. Gertsch), 1170
American Academy of Arts and Sciences : Rumford Premium for 1959 awarded to Prof. George Wald, 435
American Agriculture (Prof. Edward Higbee), *review* by Prof. A. N. Duckham, 423
American Arachnida (Theodore Savory), 1170
American Association for the Advancement of Science, and others : International Oceanographic Congress, 1093, 1502
American Chemical Society : Monograph Series No. 138, Aliphatic Fluorine Compounds (A. M. Lovelace, Douglas A. Rausch and William Postelnek), *review* by Prof. R. N. Haszeldine, 139
  1958 Pittsburgh Award of the Pittsburgh Section awarded to Dr. Max A. Lauffer, 224
  1959 Dexter Award awarded to Prof. John Read, 1304
American College and the Educated Life (Dr. Douglas M. Knight), 1769
American Documentation Institute, and others : International Conference on Scientific Information, 147
American Embassies : Appointment by the United States Department of State of Science Officers for, 15
American Geographical Society : Expedition to Chile, 17
American Geophysical Union : Grant of 25,000 dollars from the National Science Foundation, for a Conference on Mechanisms of Precipitation Formation, 1372
American Institute of the Aeronautical Sciences : Election of Sir George R. Edwards as an Honorary Fellow, 368
  Election of Dr. A. M. Ballantyne as a Fellow, 368
American Institute of Electrical Engineers (Bell Telephone Laboratories and the) : Establishment of the Kelly Award, 510
American Institute of Electrical Engineers, and others : Twelfth Annual Conference on Electrical Techniques in Medicine and Biology, 1434
American Institute of Physics, in co-operation with the National Science Foundation : To publish an English translation of the *Astronomical Journal of the Academy of Sciences*, U.S.S.R., under title *Soviet Astronomy–AJ*, 1164
American Marine Life, *review* by Dr. D. P. Wilson, 852
American Miniature Nuclear Generator, *SNAP III* (W. S. Eastwood, L. B. Mullett and J. L. Putman), 643
American Museum of Natural History : *Curator*, Vol. 1, No. 1, 223
  Bulletin, Vol. 116, Art. 1, The Spider Family Dictynidae in America North of Mexico (Prof. Ralph V. Chamberlin and Willis J. Gertsch), 1170
American Naturalists : Early, *review* by Dr. L. Harrison Matthews, 1006
American Negroes : Haptoglobin Types in (Dr. Eloise R. Giblett), 192
American Schools : Laboratory Equipment in, 1163
American Science : A Statement by the President, and Strengthening—a Report of the President's Science Advisory Committee, 1215
American Secondary Schools : Mathematics in, 1366
American Society of European Chemists : Neuberg Medal awarded to Dr. H. Albert Barker, 1304
American Society of Mechanical Engineers and Purdue University Thermophysical Properties Research Center : Symposium on the Thermal Properties of Gases, Liquids and Solids, 294
American Society of Metals : Appointment of Allan Ray Putnam as managing director, 1094
American Society of Metals (Eastern New York Chapter) : Conference on the Fracture of Engineering Materials, 1368
American (Latin) Congress of Chemistry : Seventh (Mexico), 294
American (North) *Daphnia* : The Systematics of (Dr. John Langdon Brooks), 93
Amide (Lysergic Acid Diethyl): Quantitative Measurement of the Effect of, on Mice and its Interactions with other Drugs (Dr. J. R. Smythies), 545
Amide Groups and Ammonia : Production of, in the Radiolysis of Aqueous Solutions of Protein (Dr. Winifred Bennett and Dr. Warren M. Garrison), 889
Amides (Amino-Acid), and Amino-Acids : Relationship between Proton and Metal Binding by some Peptides, (Dr. S. P. Datta, R. Leberman and Dr. B. R. Rabin), 745

Amine (Diphenyl) : Effects of Starvation and, on Carotenoids in *Phycomyces* (T. N. R. Varma, Prof. C. O. Chichester and G. Mackinney), 188
Amineoxidase : Quantitative Estimation of (Dr. George C. Cotzias and Dr. James J. Greenough), 1732
Amines (Pressor), and Neuroblastoma (Dr. J. D. P. Graham), 1733
Amino-Acetone, its Isolation and Role in Metabolism (Dr. W. H. Elliott), 1051
Amino-Acid (A New), in *Stizolobium hassjoo :* Stizolobic Acid (Prof. A. Hattori and Dr. A. Komamine), 1116
Amino-Acid Amides and Amino-Acids : Relationship between Proton and Metal Binding by some Peptides, (Dr. S. P. Datta, R. Leberman and Dr. B. R. Rabin), 745
Amino-Acid Composition of the Proteins of Barley Leaves in relation to the Mineral Nutrition and Age of Plants (Dr. B. P. Pleshkov and Dr. L. Fowden), 1445
Amino-Acid Esters : Inhibitory Action of, on the Production of Extracellular Amylase by *Penicillium chrysogenum* (Dr. L. Horváth, S. Bajusz and A. Szentirmai), 477
Amino-Acid Metabolism in Wool Roots (G. E. Rogers and P. H. Springell), 993
Amino-Acid Sequences of the Corticotropins : Patterns in the (Drew Schwartz), 464
Amino-Acid Transport : An Effect of Insulin on Peptide Synthesis independent of Glucose or (Prof. Ira G. Wool and Dr. M. E. Krahl), 1399
Amino-Acids : Activation of, in relation to the Synthesis of Silk Proteins (Prof. J. Heller, Dr. P. Szafrański and Dr. E. Sulkowski), 397
    Relationship between Proton and Metal Binding by some Peptides, Amino-acid Amides and (Dr. S. P. Datta, R. Leberman and Dr. B. R. Rabin), 745
Amino-Acids in Aqueous Solutions : Effects of Gamma-Radiation on some Carbohydrates, Hydroxyacids and (Dr. S. A. Barker, Dr. P. M. Grant, Prof. M. Stacey and Dr. R. B. Ward), 376
Amino-Acids labelled with Carbon-14 : Effect of Streptomycin on the Incorporation of, into Ribonucleic Acid and Protein in a Cell-free System of a *Mycobacterium* (T. Erdös and Agnes Ullmann), 618
Amino-Acids of Silk : Utilization of the Carboxyl Group of Glycine for the Synthesis of the, by *Bombyx mori* (Dr. S. Bricteux-Grégoire, W. G. Verly and Prof. M. Florkin), *erratum*, 294
p-Aminobenzylpenicillin : Penicillin Derivatives of (A. Ballio, Prof. E. B. Chain, F. Dentice di Accadia, Dr. G. N. Rolinson and F. R. Batchelor), 180, *erratum*, 224
γ-Aminobutyric Acid and Glutamic Acid Content of Brains of Rats treated with Toxopyrimidine (Dr. G. Rindi and G. Ferrari), 608
β-Aminoethyl*iso*thiouronium Dibromide : Anti-Thyroid Action of, in Rats (John Osmer, Dr. Robert B. Jennings and Dr. Robert M. Dowben), 470
β-Aminoethylthiosulphuric Acid : Protective Effect of, against Ionizing Radiation (Bo Holmberg and Bo Sörbo), 832
β-Amino-*iso*butyric Acid : Urinary Excretion of, in Eskimo and Indian Populations of Alaska (Dr. A. C. Allison, Dr. B. S. Blumberg and Dr. S. M. Gartler), 118
6-Aminopenicillanic Acid in Penicillin Fermentation : Synthesis of Penicillin —(F. R. Batchelor, F. P. Doyle, J. H. C. Nayler and Dr. G. N. Rolinson), 257
Aminopeptidase Activity in Cancer Cells (R. G. J. Willighagen and H. T. Planteydt), 263
Aminopeptidase (Leucine) Activity in Mast Cells (Dr. O. Braun-Falco and Dr. K. Salfeld), 51
'Aminopterin' : Selection of Bacterial Mutants of Increased Sensitivity to (Dr. Charles A. Nichol), 550
Amiran, Ruth, and others : Hazor I, an Account of the First Season of Excavations, 1955 (The James A. De Rothschild Expedition at Hazor), *review* by Peter J. Parr, 951
Ammonia : Production of Amide Groups and, in the Radiolysis of Aqueous Solutions of Protein (Dr. Winifred Bennett and Dr. Warren M. Garrison), 889
Ammonia Nitrogen : Assimilation of, by Rumen Bacteria (A. T. Phillipson, Marjorie J. Dobson and T. H. Blackburn), 402
Ammonium (Fixed), from the Soil : Release of, by Ball Milling (P. M. McDonnell, Prof. F. J. Stevenson and Dr. J. M. Bremner), 1414
Ammonium Dihydrogen Phosphate Crystals : Effect of Tartar Emetic on the Growth of (Yutaka Kunisaki), 105
Ammonium Sulphate Solutions : A Rapid Method for determining the Concentration of (Dr. John A. Whitaker and Dr. Robert Hughes), 603
Amniotic Fluid : Effect of, on Inhibition of Growth by Cortisone in Chicken Embryos (Dr. P. de Franciscis and Prof. W. Landauer), 617
Amniotic Fluid and the Foetal Lung (Bernard Towers), 1140
Amoebae : Utilization of Nutritive Spheres in the *Proteus* Group of (Sister Monica Taylor), 1458
Amoebae during Pinocytosis : Molecular Orientation at the Surface of (Ronald C. Rustad), 1058
Amounts (Small), of Water in Fluids : An Automatically Operating, Coulometric Titration Method for continually measuring (E. Barendrecht), 1181
AMPERE (Groupement), (Radio Frequency Spectroscopy Group and the) : Joint Meeting on the Study of Molecular and Atomic Motions in Solids and Liquids by Radiofrequency Methods, 652
Amperometric Determination of Sulphydryl Content of Blood and Tissues (Dr. S. K. Bhattacharya), 1327
Amphetamine Psychosis (Dr. P. H. Connell), *review* by Dr. W. R. Bett, 639
Amphibians of the United States and Canada East of the 100th Meridian : A Field Guide to Reptiles and (Robert Conant), *review* by A. G. C. Grandison, 958
Amphibians and Reptiles : Fossil (Dr. W. E. Swinton), second edition, *review*, 73
Amplifiers (Magnetic) : The Theory and Design of (Dr. E. H. Frost-Smith), *review* by J. G. Henderson, 1627
Amphipod, *Hyperia galba*, an Ectoparasite of the Jelly-fish, *Cyanea capillata* (Prof. Erik Dahl), 1749
Amylase (Extracellular) : Inhibitory Action of Amino-Acid Esters on the Production of, by *Penicillium chrysogenum* (Dr. L. Horváth, S. Bajusz and A. Szentirmai), 477
Amylo Process : Unfermentable Sugars in Barley Mash fermented by the (Hideo Ono and Michio Dazai), 1055
Amyloid of Diverse Origins : Electron Microscopic Observations on a Fibrous Component in (Dr. Alan S. Cohen and Dr. Evan Calkins), 1202
Amylose : Synthesis of, by Potato D-Enzyme (Dr. Gwen J. Walker and Dr. W. J. Whelan), 46
Anaerobic Digestion : Gas-Chromatographic Observation of the Reduction of Carbon Dioxide to Methane during (J. Chmielowski and Peter C. G. Isaac), 1120
Analbuminaemic Subject : Albumin labelled with Iodine-131 in an (T. Freeman, C. M. E. Matthews, Dr. A. S. McFarlane, H. Bennhold and E. Kallee), 606
Analisi : La Disputa Leibniz–Newton sull' (translated into Italian by Dr. G. Cantelli), *review* by L. Roth, 1081
Analogues (Lipid-soluble), of Acetylcholine : Distinction between Sodium and Potassium in Change in Permeability effected by (Dr. Wolf D. Dettbarn), 465
Analysis : Biochemical, *review* by Dr. I. D. P. Wootton, 779
    Colorimetric (Noel L. Allport and Dr. J. W. Keyser), Vol. I, Determinations of Clinical and Biochemical Significance, second edition, *review* by Dr. N. R. Lawrie, 207
    Modern Tauberian, *review* by Prof. T. A. A. Broadbent, 1626
Analysis of Artificial Satellite Orbits : Density of the Atmosphere at Heights between 200 km. and 400 km., from (D. G. King-Hele), 1224
Analysis by Gas Chromatography of a 'Pure' Sample with an 'Impure' Carrier (V. Willis), 1754
Analysis of Hydrocarbons (Dr. H. M. Frey), 743 ; (Dr. J. A. Barnard and Dr. H. W. D. Hughes), 744
Analysis of Light Hydrocarbon Gas Mixtures (Dr. J. A. Barnard and Dr. H. W. D. Hughes), 250
Analysis of Mast Cells by means of Polarization Microscopy (Prof. Leslie Horváth), 1067
Analysis of Noise and Vibration : New Techniques in the (Acoustics Group of the Physical Society and the Institute of Physics Symposium on), 438, 794
Analysis of Scale-rich Material from Wool : Separation and (Dr. J. H. Bradbury), 305
Analysis (Applied), in the U.S.S.R., *review* by Prof. T. A. A. Broadbent, 1766
Analysis (Biochemical) : Methods of (edited by Prof. David Glick), Vol. 6, *review* by Dr. I. D. P. Wootton, 779
Analysis (Chemical) : Magnetometric Titration—a New Method of (Dr. M. S. Blackie and Dr. V. Gold), 1804
Analysis (A Chromatographic), for Ricinine (Trevor Robinson and Elvin Fowell), 833
Analysis (Combinatorial) : An Introduction to (John Riordan), *review* by Dr. L. S. Goddard, 970
Analysis (Higher) : Approximate Methods of (L. V. Kantorovich and V. I. Krylov), translated from the Russian by Curtis D. Benster, *review* by Prof. T. A. A. Broadbent, 1766
Analysis (*In vitro*) of a Mammalian Tumour Virus (Dr. Leo Sachs, Dr. Marian Fogel and Ernest Winocour), 663
Analysis (X-Ray Fluorescence) : Estimation of Strontium in Animal Bone using (W. M. B. Roberts), 887
Analytical Chemistry : Separation Processes in (Royal Institute of Chemistry Symposium on), 934
Analytical Chemistry, Society for : Election of Officers, 1024
Analytical Histology and Histo-Chemistry : Methods of (Edward Gurr), *review* by S. Bradbury, 211
Anantaraman, Sita : Metacercaria (Allocreadioidea) in the Planktonic Ctenophore, *Pleurobrachia globosa* Moser 1903, from the Madras Coast, 1407
Anatomical, Physiological and Anthropometric Principles in the Design of Office Chairs and Tables (Dr. W. F. Floyd and Dr. D. F. Roberts), 1022
Anatomie de *Latimeria chalumnae* (J. Millot et J. Anthony), Tome I, Squelette, Muscles et Formations de Soutien, *review* by Dr. E. Trewavas, 566
Anatomy of a Coelacanth, *review* by Dr. E. Trewavas, 566
Anatomy (Comparative) : Zoology and, at Dublin, 1716
Anbar, Dr. M., and others : Effect of Monofluorosulphonate, Difluorophosphate and Fluoroborate Ions on the Iodine Uptake of the Thyroid Gland, 1517
Ancient Ireland, *review* by Joseph Raftery, 1704
Ancient Manure : Marl, an (G. E. Fussell), 214
Ancient Periods : Plant Ecology of (Prof. Tom M. Harris), 1370
Ancillary Mathematics (Prof. H. S. W. Massey and H. Kestelman), *review* by Prof. T. A. A. Broadbent, 1703
Anderson, A. Elving, and others : Variables related to Human Breast Cancer, *review* by Dr. L. Foulds, 955
Anderson, A. J. (Meyer, D. R., and) : Temperature and Symbiotic Nitrogen Fixation, 61
Anderson, B. W. : Gem Testing, sixth edition, *review* by Dr. W. Campbell Smith, 781
Anderson, Helen M., and Turner, Dr. Joseph C. : Preparation and the Haemoglobin Content of Red Cell 'Ghosts', 112
Anderson, J. H. R.: Humid Tropics Vegetation (Tropical Peat-Swamps), 795
Anderson, Prof. J. M. : Emission of Slow Secondary Electrons, 241
Anderson, Prof. John M. (Guthrie, Mary J., and) : General Zoology, *review* by Dr. V. Fretter, 1290
Anderson, Dr. J. S. : Appointed director of the National Chemical Laboratory, Teddington, 1719
Anderson, Dr. Kitty : Appointed a member of the University Grants Committee, 86
Anderson, Dr. P. J. : Electrical Double Layer in Colloid Science (Dispersions of several Inorganic Oxides in Dilute Inorganic Electrolytes), 78
Anderson, S. G. (Ada, G. L., and) : Yield of Infective 'Ribonucleic Acid' from Impure Murray Valley Encephalitis Virus after Different Treatments, 799
Anderson, Comdr. W. R. : Awarded the Patron's Medal of the Royal Geographical Society, 292
Andrea, Dr. J. H. : Relaxation Processes (Ultrasonic Relaxation Measurements in Liquids), 584
Andrew, Prof. E. R., and others: Removal of Dipolar Broadening of Nuclear Magnetic Resonance Spectra of Solids by Specimen Rotation, 1802
Andrewartha, Dr. H. G. : Density-Dependent Factors in Ecology, 200
Andrews, D. R. (Burt, A. D., and) : Stereophonic Sound Recording, Reproduction and Broadcasting (Magnetic Tape Recording), 1720

Androgens in the Bovine Testis and Spermatic Vein Blood (H. R. Lindner), 1605
Andromeda Nebula at 408 Mc./s.: A High-resolution Survey of the (Dr. M. I. Large, D. S. Mathewson and C. G. T. Haslam), 1250
Andrysek, Oskar, and Schück, Ota: Absorption of Radioiodine through the Bladder-Wall in the Rabbit, 893
Anfinsen, Jr., C. B., and others (edited by): Advances in Protein Chemistry, Vol. 12, *review* by Dr. M. F. Perutz, 1290
Angell, Montgomery B.: Awarded the Plaque of the New York Academy of Medicine, 294
Anglo-American Library Associations (R. D. MacLeod), 1021
Anglo-Soviet Educational and other Exchanges: Discussions on (Soviet Relations Committee of the British Council and the Soviet State Committee for Cultural Relations with Foreign Countries), 582
A. or mμ in Electron Microscopy (Dr. John R. Baker), 416
Angular Momentum: Elementary Theory of (M. E. Rose), *review* by Prof. N. Kemmer, 705
Angular Momentum in Quantum Mechanics (E. R. Edmonds), *review* by Prof. N. Kemmer, 705
Angwin, Sir Stanley: *Obituary* by Sir Gordon Radley, 1638
Angyal, Prof. S. J.: Awarded the H. G. Smith Memorial Medal of the Royal Australian Chemical Institute, 794
3,6 Anhydrogalactosediethylmercaptal: Determination of Galactosediethylmercaptal and, with the Anthrone and Seliwanoff Reagents (W. Yaphe), 44
Anhydrous Gamma Alumina: Evidence for a Variable Long-range Order in nearly (Prof. G. W. Brindley and Dr. M. Nakahira), 1620
Anhydrous Sodium Soaps: Structure of, at High Temperatures (A. Skoulios and Dr. V. Luzzati), 1310
Anhydrous Sodium Sulphate: Polymorphic Transitions in (Dr. C. N. R. Rao and L. V. Gregor), 1391
Aniline (Dimethyl): Kinetic Isotope Effect in the Bromination of (P. G. Farrell and Dr. S. F. Mason), 250
Animal Bone: Estimation of Strontium in, using X-Ray Fluorescence Analysis (W. M. B. Roberts), 887
Animal Bones: Radioactivity of Soils, Plant Ashes and (Sir Ernest Marsden), 924
Animal Book: The Cherry Kearton (Cherry Kearton), *review* by J. E. Hill, 1628
Animal Ecology—Aims and Methods (A. Macfadyen), *review* by Dr. E. B. Ford, 707
Animal Ecology To-day (Prof. F. S. Bodenheimer), *review* by Dr. A. Milne, 1220
Animal Husbandry at the Royal Veterinary College, 365
Animalium: De Motu Locali, 1627 (William Harvey), edited, translated and introduced by Dr. Gweneth Whitteridge, *review* by Prof. K. J. Franklin, 1486
Animals: Harvey on Movement in, *review* by Prof. K. J. Franklin, 1486
  The Work Output of—Flight by Birds and by Man-power (Dr. D. R. Wilkie), 1515
Animals (Domestic), in New Zealand: Diseases of (prepared by the Technical Committee of the New Zealand Veterinary Association, Inc.), *review* by Dr. J. N. Oldham, 967
Animals (Farm): Glycosidases in some (J. Conchie, June Findlay and Dr. G. A. Levvy), 615
Animals (Indian): Status to-day of Four Rare (E. P. Gee), 367
Animals (Laboratory): Effect of 1,6-Di-(2-Bromoethylamino)-1,6-Dideoxy-D-Mannitol Dihydrobromide on Tumours of (Prof. J. Baló, G. Kendrey, J. Juhász and I. Besznyák), 395
Animals (Non-immunized and Immunized): Factors Inhibiting and Stimulating Growth of *Mycobacteria* in the Blood and Serum of (J. Hubáček and I. Málek), 187
Animals (Predatory), in Spain, 1782
Animals (Small): Measuring Productivity in Breeding of (Dr. W. Lane-Petter, Annie M. Brown, Margaret J. Cook, G. Porter and A. A. Tuffery), 339
  A Photographic Method for Recording Activity and Behaviour in a Group of (Dr. D. K. Edwards), 625
Anion Inhibition of α-Glycerophosphate Dehydrogenase (Dr. Otto Z. Sellinger and Dr. O. Neal Miller), 889
Anionic Surface-Active Agents: Decomposition of, by Soil Bacteria (Dr. F. A. Skinner), 548
Annau, E.: Splitting of the Electrophoretic Pattern of Serum Albumin during Short-Term Action of Pepsin at Room Temperature, 190
Annealing (Thermal), of Chemical Radiation Damage (Dr. A. G. Maddock and S. R. Mohanty), 86
Annelids and the Arthropods: Link between the, 1782
Annual Rainfall: World Variation in (J. F. Griffiths), 132
Annual Review of Biochemistry (edited by J. Murray Luck, in association with Frank W. Allen and Gordon Mackinney), Vol. 27, *review* by Prof. F. G. Young, 961
Annual Review of Microbiology (edited by Charles E. Clifton, in association with Sidney Raffel and Mortimer P. Starr), Vol. 12, *review*, 1219
Annual Review of Plant Physiology (edited by A. S. Crafts, in association with Leonard Machlis and John G. Torrey), Vol. 9, *review* by Prof. W. Stiles, 1703
Anodic Films (Aluminium Oxide): Sealing of (Dr. R. M. Hinde, E. A. Kellett and P. H. Harris), 39
Anodic Oxidation: Refractive Index of Uranium Oxide produced by (A. E. Stebbens and Dr. L. L. Shreir), 1113
Anomalous Night-Time Reception of a Major Solar Radio Burst (Prof. Alex. G. Smith, T. D. Carr and W. H. Perkins), 597
Anomaly (Spacing), in Electron Microscope Images of Crystal Lattices (Dr. H. Hashimoto and Dr. H. Yotsumoto), 1001
Anopheles aquasalis Curry: Resistance of, to Dieldrin in Trinidad (T. A. Omardeen), 131
Anopheles gambiae: Relationship between Salinity and Breeding of, in North-Eastern Tanganyika (A. Smith and J. W. Vail), 1203
Anopheline Densities in Huts on the Pare Mountains: Effect of Residual House Spraying in the Plains on (Dr. A. Smith), 198
Ansell, A. D.: Awarded a John Murray Travelling Studentship in Oceanography and Limnology for 1959 by the Royal Society, 1365
Anserine Formation: Pathways and the Physiological Site of (Prof. Theodore Winnick and R. E. Winnick), 1466
Ansevin, Allen T., and Lauffer, Prof. Max A.: Native Tobacco Mosaic Virus Protein of Molecular Weight 18,000, 1601
Anson, D., and others: Examination of Particulate Matter on Filter Membranes, 1000
Anson, M. L., and others (edited by): Advances in Protein Chemistry, Vol. 12, *review* by Dr. M. F. Perutz, 1290
Antagonism of Choline and Inositol (Dr. B. W. Agranoff and M. R. Spivey Fox), 1259
Antarctic Ice-Sheet: Characteristics of the (Royal Astronomical Society and the British Glaciological Society Geophysical Discussion on), 1575
Antarctic Meteorology (Dr. E. B. Kraus), 1503
Antarctic Report (United Kingdom), to the fifth meeting of the Special Committee for the International Geophysical Year, 1718
Antarctic Research, British National Committee on: To co-ordinate British Antarctic Activities, 292
  Appointment of Sir Raymond Priestley as chairman, 292
Antarctic Research Programme, United States: Appointment of Albert P. Crary as chief scientist, 1090
Antarctica: Thickness of the Earth's Crust in (F. F. Evison, C. E. Ingham and R. H. Orr), 306
Antarctica near Mawson, 1956: Marine Studies in the Inshore Waters of (Dr. J. S. Bunt), 1541
Anterior Pituitary: Influence of the, on the Ageing Process in the Ovary (Dr. E. C. Jones and Prof. P. L. Krohn), 1155
Anterior Pituitary Glands (Sheep): Bioassay of (Dr. D. R. Lamond, H. M. Radford and A. L. Wallace), 1597
Anthocyanidins from Leucoanthocyani(di)ns: Mechanism of Formation of (Dr. David G. Roux and M. C. Bill), 42
Anthocyanins from Plant Extracts: Separation of (Dr. B. V. Chandler and Dr. T. Swain), 989
Anthony, Dr. H. D.: Science and Religion in Seventeenth-Century England, *review*, 964
Anthony, H. S.: Association between Psychomotor Behaviour and Delinquency, 343
Anthony, J. (Millot, J., et): Anatomie de *Latimeria chalumnae*, Tome I, Squelette, Muscles et Formations de Soutien, *review* by Dr. E. Trewavas, 566
Anthracite of the Don: Derivatographic Investigation of the (M. Weltner), 1254
Anthrenus verbasci (L.) (Col., Dermestidae): Control of Diapause by an 'Internal Clock' in (G. M. Blake), 126
Anthrone and Seliwanoff Reagents: Determination of Galactosediethylmercaptal and 3,6 Anhydrogalactosediethylmercaptal with the (W. Yaphe), 44
Anthropological Research, Wenner-Gren Foundation for: Viking Fund Medals and Awards of 1,000 dollars awarded to Prof. Raymond W. Firth, Prof. Henri V. Ballois and Dr. Jesse D. Jennings, 1434
Anthropological Studies, *review* by Dr. Kenneth Little, 70
Anthropology: Cambridge, *review* by Dr. Rodney Needham, 1625
Anthropology, Department of (Government of India): Appointment of N. K. Bose as director, 719
Anthropology (Physical): The Scope of, and its Place in Academic Studies—a Symposium held at the Ciba Foundation, 1957 (edited by D. F. Roberts and J. S. Weiner), *review* by Dr. Kenneth Little, 70
Anthropology (Social): Method in (Prof. A. R. Radcliffe-Brown), edited by Prof. M. N. Srinivas, *review* by Dr. Kenneth Little, 70
Anthropometric Principles in the Design of Office Chairs and Tables: Anatomical, Physiological and (Dr. W. F. Floyd and Dr. D. F. Roberts), 1022
Antibiotic Action of Cycloheximide (Actidione): Reversal of, by Bivalent Metal Ions (M. Blumauerová and J. Stárka), 261
Antibiotic Combinations: Application of Logarithms to the Base 2 in the Use of Exponential Dilution Series for the Study of (H. J. Oskam and A. Koelman), 840
Antibiotic (New), Kanamycin: Basic and Clinical Research of the (Maxwell Finland, and 93 other authors), 1570
Antibiotics (Czechoslovak Academy of Sciences and the Purkyne Medical Society Symposium on), 154
Antibiotics: Micro-volume Drop-plate Assay of (Dr. M. R. S. Iyengar), 684
  New Types of Salting-out Paper Chromatograms of (Dr. Joseph Úri), 1188
Antibodies: Homologous Species Neoplastic (Dr. Hoy A. Cranston and Frederic O. Eggert), 1471
Antibodies (Precipitating), present in the Serum of Cattle recovering from Foot-and-Mouth Disease: Changes in Specificity and Electrophoretic Mobility of the (F. Brown and J. H. Graves), 1688
Antibody: Effect of Hydrolysis by Papain on the Combining Sites of an (Dr. A. Nisonoff and D. L. Woernley), 1325
Antibody (Staphylococcal), in Human Serum: Measurement of a, by a Mouse Protection Test (Dr. Myron W. Fisher), 1692
Antibody Conjugate (Electron-dense): Preparation of an (Prof. S. J. Singer), 1523
Antibody Decay (Passive), in Thyroidectomized Rabbits (Dr. Ignatius L. Trapani, Dr. Allen Lein and Dr. Dan H. Campbell), 982
Antibody Formation: Failure of Ribonucleoprotein to transfer (Dr. B. D. Janković, Dr. K. Isaković and J. Horvat), 1400
Antibody Formation by Isolated Spleen Cells transferred to Recipients in Absence of Homotransplantation Reaction (Dr. Z. Trnka and I. Riha), 546
Antibody Formation in Tissue Culture (Marvin Fishman), 1200
Antibody Formation by Transferred Cells: Presence of Antigen—a Factor determining the Duration of (Dr. J. Sterzl), 547
Antibody Production: Changes in Lymphocytes during (K. W. Keohane and W. K. Metcalf), 195
Antibody (Serum), and γ-Globulin in Baby Rabbits after Transfer of Ribonucleoprotein from Adult Rabbits (Dr. Miroslava Hrubešova, Dr. Brigitte A. Askonas and Dr. J. H. Humphrey), 97
Anticoagulant Action of Fibrin Surfaces on Mammalian Blood (Dr. A. L. Copley, D. Steichele, M. Spradau and R. S. Thorley), 1683
Anti-complementary Effect (Apparent): Normal Components of Guinea Pig Serum which may cause Antigens to show an (M. M. H. Sewell), 1062
Antifungal Substance in the Corn Plant and its Effect on Growth of Two Stalk-rotting Fungi (N. J. Whitney and C. G. Mortimore), 341
Antigen: Penicillin as an (K. C. Watson, S. M. Joubert and M. A. E. Bennett), 468
  Presence of—a Factor determining the Duration of Antibody Formation by Transferred Cells (Dr. J. Sterzl), 547

Antigen (Group *A*) : Changes in the, in a Case of Leukaemia (Dr. E. R. Gold, Dr. Geoffrey H. Tovey, W. E. Benney and F. J. W. Lewis), 892
Antigenic Equivocation : Radiosensitivity as a Function of (Dr. L. Cohen and Dr. A. Cohen), 692
Antigenic Relationships : A Critical Test of (Dr. J. G. Feinberg and Hazel Grayson), 987
Antigenic Stimulus of Exsheathing Fluid in Self-Cure of Sheep infected with *Haemonchus contortus* (E. J. L. Soulsby, R. I. Sommerville and D. F. Stewart), 553
Antigens : Estimation of the Size of, by Gel Diffusion Methods (Dr. A. C. Allison and Dr. J. H. Humphrey), 1590
  Viruses, Genes and, *review* by Prof. F. C. Bawden, 636
Antigens to show an Apparent Anti-complementary Effect : Normal Components of Guinea Pig Serum which may cause (M. M. H. Sewell), 1062
Antigens as Specific Precipitates on Paper Electrophoresis Strips : Detection of (S. Buttery), 686
Antigens (A and B), in Platelets : Histochemical Demonstration of (Dr. B. D. Jankovič and K. Arsenijevič), 695
Antigens (Adenovirus) : Study of, by Immunoelectrophoresis (Dr. H. G. Pereira, Dr. A. C. Allison and Dr. C. P. Farthing), 895
Antigens (Liver), of Mouse Hepatitis : Complement Fixation with Tissue Culture and (Dr. Theodore J. Starr and Dr. Morris Pollard), 1690
Anti-Gm : A New Haemagglutinating Substance in the Gm System (Dr. Morten Harboe), 1468
Anti-Locust Research Centre : Annual Report of the Director (1957-58), 703
  Retirement of Dr. B. P. Uvarov from the directorship, 1160
  Appointment of Dr. T. H. C. Taylor as director, 1160
Antimetabolite (Glucose), (2-deoxy-D-glucose) : Inhibition of Influenza Virus Multiplication with a (Prof. Edwin D. Milbourne), 271
Antimicrobial Substances from Resistant and Non-resistant Seeds (Dr. Jasper C. Maruzzella and Dr. Martin Freundlich), 972
Antioxidants (Fat) : Basic Substances as Synergists for (H. S. Olcott and E. J. Kuta), 1812
Anti-Parkinsonian Drugs : Use of 'Tremorine' for screening (E. M. Trautner and S. Gershon), 1462
Antiquarian Horological Society : Annual General Meeting, 1094
Antiserum (Insulin) : Production of Acute Insulin Deficiency by Administration of (P. H. Wright), 829
Anti-Thyroid Action of β-Aminoethyl*iso*thiouronium Dibromide in Rats (John Osmer, Dr. Robert B. Jennings and Dr. Robert M. Dowben), 470
Anti-Tumour Activity of 5-Mercaptouracil (Thomas J. Bardos, Albert Segaloff and Julian L. Ambrus), 612
Anti-Tumour Agents : 'Dual Antagonists' ; Alkyl N-(*bis*-(ethylenimido) phosphoro)-carbamates ; a New Series of (Thomas J. Bardos, Zinon B. Paranastassiou, Albert Segaloff and Julian L. Ambrus), 399
Antiviral Activity of Lysozyme (Prof. Rodolfo Ferrari, Dr. Carlo Callerio and Dr. Giuseppe Podio), 548
Antonini, E., and others : Oxygen Equilibrium of Human Haemoglobin in Strong Salt Solutions, 827
Antropov, P. Y. : The Iron Ore Deposits of the Kursk Magnetic Anomalies, 1028
Ants on a Scent Trail : Interaction between (J. H. Sudd), 1588
Anurans : Number of Fibres in the Optic Nerve and the Number of Ganglion Cells in the Retina of (Dr. H. R. Maturana), 1406
Aorta (Rabbit) : Inhibition of Sensitiveness to Nicotine of, by Reserpine, Hexamethonium, Ethyl Flavone-7-Oxyacetate and other Compounds (Dr. I. Setnikar and M. Ravasi), 898
Aorta, Coronary Arteries and Circulus Willisii of Atherosclerotic Individuals : Composition of Lipids isolated from the (Prof. C. J. F. Böttcher, F. P. Woodford, C. Ch. Ter Haar Romeny, E. Boelsma and C. M. Van Gent), 47
Aortic Medial Calcification and Lowered Metabolism in Ground Squirrels (Dr. George R. Zimmerman and Prof. G. Edgar Folk, jun.), 754
Ape-Man-bearing (The Transvaal), Cave Deposits (C. K. Brain), 1433
Apex (Shoot) : Use of Radioactive Tracers in Studies of the (Dr. A. Booth, Dr. E. G. Cutter, Dr. S. N. Postlethwait, B. R. Voeller and Prof. P. F. Wareing), 1580
Aphid : Secretion of Two Types of Saliva by an (Dr. P. W. Miles), 756
Aphididae (Homoptera) of East Africa : A Study of the (V. F. Eastop), *review* by Dr. W. J. Hall, 208
Aphids : African, *review* by Dr. W. J. Hall, 208
Apolocystis elongata, Phillips and MacKinnon : Observations by Electron Microscopy on the Structure of an Acephaline Gregarine (Dr. D. Lacy and H. B. Miles), 1456
Apparatus and Applications of Mass Spectroscopy, *review* by Prof. K. T. Bainbridge, 638
Apparent Anti-complementary Effect : Normal Components of Guinea Pig Serum which may cause Antigens to show an (M. M. H. Sewell), 1062
'Apparent Protein' in the Human Red Cell : Haemoglobin and (Dr. Eric Ponder), 1330
Appearance of a Phosphorus Compound in Platelet-rich Plasma on Clotting (Dr. G. V. R. Born and Dr. M. P. Esnouf), 478
Appendages of Bacteria : Non-Flagellar (Dr. Charles C. Brinton, jun.), 782
Appendix (Rabbit) : Effects of X- and Ultra-violet Irradiation on the Incorporation of Phosphorus-32 into Isolated Nuclei of (Yuong-Tchel Tchoe and Prof. A. Sibatani), 1334
Apple-Scoops (Dr. J. Menzies Campbell), 1542
Apples (Stored) : Control of Superficial Scale in (W. High Smith), 760
Application of Logarithms to the Base 2 in the Use of Exponential Dilution Series for the Study of Antibiotic Combinations (H. J. Oskam and A. Koelman), 840
Application of Standards of Radioactivity : Preparation, Maintenance and (W. B. Mann and H. H. Seliger), 1023
Applications of the Electron Microscope : Techniques and (Cornell University Annual Summer Laboratory Course in), 1094
Applications to Fundamental Problems of Physics : Information Theory and its (Prof. L. Brillouin), 501
Applications of Mass Spectroscopy : Apparatus and, *review* by Prof. K. T. Bainbridge, 638
Applications of Random Noise Theory : Principles and (Dr. Julius S. Bendat), *review* by R. A. King, 353
Applications (Industrial) : Electronic Digital Computers and their (Conference at the Birmingham College of Technology), 154
Applications (Scientific), of Science, *review* by Dr. Cecil Gordon, 424
Applied Analysis in the U.S.S.R., *review* by Prof. T. A. A. Broadbent, 1766
Applied Bacteriology, Society for : Symposium on Lactobacilli, 1234
Applied Chemistry (Pure and) : Seventeenth International Congress of, 1368
Applied Chemistry (Pure and), International Union of : Formation of a Special Group under the auspices of the Analytical Chemistry Section, to make recommendations for a standard terminology in Gas Chromatography, 722
  Nomenclature of Organic Chemistry, 1957, *review* by Dr. E. H. Rodd, 960
  A Proposed International Chemical Notation (prepared by the Commission on Codification, Ciphering and Punched Card Techniques), tentative version subject to revision, *review* by Dr. E. H. Rodd, 960
Applied Chemistry (Pure and), International Union of (Commission of Geochemistry) : Symposium on Geochemistry, 1719
Applied Chemistry (Pure and), International Union of (organized by the Chemical Society and sponsored by the) : Fourth International Conference on Co-ordination Chemistry, 1784
Applied Mathematics in the Soviet Union, 863
Applied Mechanics (Theoretical and) : Fourth Congress on (Indian Society of Theoretical and Applied Mechanics), 366
Applied Mechanics (Theoretical and), Indian Society of : Fourth Congress on Theoretical and Applied Mechanics, 366
Applied Pharmacology, Toxicology and, Vol. 1, No. 1, 650
Approach (The Biographical), to John Dalton (Frank Greenaway), *review* by Prof. J. R. Partington, 1765
Approach (A Geometrical), to the Structure of Liquids (Prof. J. D. Bernal), 141
Approaches (Experimental), to the Problems of Growth and Form in Plants (Experimental Morphology Group of the Linnean Society Symposium on), 584
Approximate Methods of Higher Analysis (L. V. Kantorovich and V. I. Krylov), translated from the Russian by Curtis D. Benster, *review* by Prof. T. A. A. Broadbent, 1766
Approximate Wave Functions : Use of, for Extrapolation to True Energy Values (P. G. Dickens, Dr. J. W. Linnett and D. Schofield), 175
Aqueous Humour of the Hippopotamus (C. P. Luck and P. G. Wright), 1595
Aqueous Solution : Interaction between Organic Hydroxy Acids and Germanic Acid in (E. R. Clark), 536
Aqueous Solutions : Effects of Gamma-Radiation on some Carbohydrates, Hydroxyacids and Amino-acids in (Dr. S. A. Barker, Dr. P. M. Grant, Prof. M. Stacey and Dr. R. B. Ward), 376
Aqueous Solutions mixed with Solid Crystalline Fluors : Radioassay of (Dr. Daniel Steinberg), 1253
Aqueous Solutions of Protein : Production of Amide Groups and Ammonia in the Radiolysis of (Dr. Winifred Bennett and Dr. Warren M. Garrison), 889
Arabinose and Xylose : Production of Acid from, by Strains of *Azotobacter* (Vagn Jensen), 1536
Arachnida : American (Theodore Savory), 1170
Aragón, F., and others : β-Type Interlamellar Sorption Complexes, 740
'Araldite' : Preparation and Sectioning of Tissues embedded in, for Electron Microscope Examination (J. M. Davis), 200
Arambourg, C., et autres : Archives de l'Institut de Paléontologie Humaine, Mémoire 29, La Grotte de Fontéchevade, Troisième partie, Géologie et Paléontologie, 1369
Araz, A., and others : Action of Nicotinamide on Acetoacetate Metabolism of Liver Homogenates of Normal and Alloxanized Rats, 184
Arc (Electric), in Welding (University of Birmingham Conference on), 1164
Arc Stage of Electrical Discharge : Effects of, on Ignition of Inflammable Gas (I. Berz), 669 ; (W. Nethercot and H. G. Riddlestone), 669
Archaeological Structures : Denudation and Burial of (Formation by Section H of the British Association for the Advancement of Science of a special Committee to investigate the), 1233
Archaeologist : Soils for the (Dr. I. W. Cornwall), *review* by Dr. Alex Muir, 1355
Archer, Dr. R. K. : Feulgen–Naphthoic Acid Hydrazide Reaction applied to Blood Smears, 820
Archer, Dr. R. K., and Flute, P. : Heparin and Thromboplastin Generation in the Horse, 235
Archibald, J. D. H. (Bowman, J.C., and) : Effect of Controlled Lighting on Production Characters in the Fowl, 1138
Architectural Science Review, Vol. 1, No. 1, 1570
Arctic: Meteorological and Ionospheric Studies in the, *review* by James Paton, 279
  Venture to the (edited by R. A. Hamilton), *review* by Dr. T. E. Armstrong, 1081
Arctic Skua : Possibility of Assortive Mating in the (P. O'Donald), 1210
Arends, Dr. Tulio (Gallango de Rodríguez, Dr. M. L., and) : Distribution of Haptoglobins in Native Venezuelans, 1465
Arginase in Rabbit Epithelium : Induction of, by the Shope Rabbit Papilloma Virus (Prof. Stanfield Rogers), 1815
Arginine : Formation of Urea from, in the Brain of the Living Rat (Michael B. Sporn, Wesley Dingman, Alfred Defalco and Robert K. Davies), 1520
Arginine Esterase Activity of 'Blood Thromboplastin' (Phyllis M. Arscott, J. L. Koppel and John H. Olwin), 753
Argus High-Altitude Geophysical Experiments (Dr. Alan T. Waterman and Dr. Detlev W. Bronk), 1019
Arid Zones (Unesco Symposium on), 1234
Arkwrights, 1758-1830 : The Strutts and the—a Study of the Early Factory System (R. S. Fitton and A. P. Wadsworth), *review* by Prof. W. H. G. Armytage, 635
Armarego, W. L. F., and others : Metal-Chelating Properties of Plant-Growth Substances, 1176
Armed Forces—National Research Council Committee on Bio-Astronautics to advise on the Biological or Medical Aspects of Space Exploration, 651
Armour Research Foundation (Information Systems Branch of the Office of Naval Research and the) : Interdisciplinary Conference on Self-Organizing Systems, 86
'Arms and the Man', *review* by R. Brightman, 952
Arms Race : The—a Programme for World Disarmament (Philip Noel-Baker), *review* by R. Brightman, 952
Armstrong, A. H. : Neuro-Mathematics, *review*, 350
Armstrong, D. T., and others : Mechanism of Action of Insulin, 1123

Armstrong, Edward A. : The Folklore of Birds, *review* by M. C. Burkitt, 1422
Armstrong, Dr. E. B. : Satellite Research, *review*, 963
Armstrong, Dr. T. E. : Venture to the Arctic, *review*, 1081
Army Office of Ordnance Research (United States) : Grant of 27,243 dollars to Prof. L. A. Page (University of Pittsburgh), to begin a research programme on Low-energy Nuclear and Electron Physics, 86
Army (British), in the Second World War : Psychiatry in the (Dr. Robert H. Ahrenfeldt), *review* by Dr. D. Russell Davis, 208
Armytage, Prof. W. H. G. : Early Textile Technologists, *review*, 635
Arnold, Dr. A. H. M. : Measurement and Control in Electrical Engineering, 89
Arnstein, Dr. H. R. V. : Radioactive Isotopes in Biochemistry, *review*, 1149
Arnstein, Dr. H. R. V., and Simkin, Dr. J. L. : Vitamin B_{12} and Protein Biosynthesis—Vitamin B_{12} and Biosynthesis in Rat Liver, 523
Aromatic Fluorocarbons : A New General Route to (B. Gething, Dr. C. R. Patrick, Prof. M. Stacey and Prof. J. C. Tatlow), 588
Aromatic Hydrocarbons : Polarography of (H. J. Gardner), 320
Aromatic Hydrocarbons (Polycyclic), added to Wax : Milk as an Eluant of (Dr. Hans L. Falk, Dr. Paul Kotin and Adele Miller), 1184
Aronsson, B., and others : Borides and Silicides of the Platinum Metals, 1318
Arrhenius, Dr. O. : Phosphates and Organic Substances in Nitrogen Deficiency, 513
Arrow, Kenneth J., and others : Studies in the Mathematical Theory of Inventory and Production, *review* by Dr. L. S. Goddard, 1557
Arscott, Phyllis M., and others : Arginine Esterase Activity of 'Blood Thromboplastin', 753
Arsenijevič, K. (Jankovič, Dr. B. D., and) : Histochemical Demonstration of A and B Antigens in Platelets, 695
Art : Aboriginal, *review* by Dr. Phyllis Kaberry, 1080
Art of Grafting, *review* by S. A. Pierce, 958
Art of Lecturing (Dr. G. Kitson Clark and Comdr. E. Bidder Clark), enlarged edition, 1623
Art and Science of Management, 419
Artemia cultured in Sea Water containing Phosphorus-32 : A Sex Difference in Radioactivity of (Prof. Daniel S. Grosch and Mary Ellen Plumb), 122
Arteries of several Species : Distribution of Alkaline Phosphatase in the (Dr. Manuel René Malinow, Martha A. Fernandez, Alvaro L. Gimeno and Grato E. Bur), 1262
Arteries (Coronary), and Circulus Willisii of Atherosclerotic Individuals : Composition of Lipids isolated from the Aorta, (Prof. C. J. F. Böttcher, F. P. Woodford, C. Ch. Ter Haar Romeny, E. Boelsma and C. M. Van Gent), 47
Arthropod-borne Viruses : Plaque Production with Yellow Fever and related (J. S. Porterfield), 1069
Arthropods : Insecticide Resistance in (Dr. A. W. A. Brown), 1508
  Link between the Annelids and the, 1782
Arthurs, A. M. : Appointed lecturer in engineering mathematics at Queen's University, Belfast, 1024
Artificial Aurora : The Samoan (Dr. H. Elliot and J. J. Quenby), 810
Artificial Earth Satellites (Royal Society Programme), 1640
  Deduction of Ionospheric Electron Content from the Faraday Fading of Signals from (W. T. Blackband, B. Burgess, I. L. Jones and G. J. Lawson), 1172
  Table of (Royal Aircraft Establishment), 1566
Artificial Planet : The Russian, 83
Artificial Planet 2, 720
Artificial Planets : Verification of General Relativity by means of (John J. Gilvarry), 666
Artificial Satellite Orbits: Density of the Atmosphere at Heights between 200 km. and 400 km. from Analysis of (D. G. King-Hele), 1224
Artificial Satellites : Corpuscular Radiation and the Acceleration of (Dr. Luigi G. Jacchia), 1662
  Two Atmospheric Effects in the Orbital Acceleration of (Dr. Luigi G. Jacchia), 526
Artificially Induced Residual Stresses : Improvement of the Fatigue Strength of Notched Specimens by (T. R. Gurney), 883
Arts, Royal Society of : Swiney Prize awarded to Dr. Keith Simpson, 368
Arts and Sciences, American Academy of : Rumford Premium for 1959 awarded to Prof. George Wald, 435
Arts and Sciences, Connecticut Academy of : Memoirs, Vol. 13, The Systematics of North American *Daphnia* (Dr. John Langdon Brooks), 93
Arya, V. P. : Awarded a Ciba Fellowship for 1959-1960, 1161
Aryloxy-alkylcarboxylic Acids : Effect of Substitution in the Side-Chain on β-Oxidation of, by *Nocardia opaca* (D. M. Webley, R. B. Duff and V. C. Farmer), 748
Asbestos : Tensile Strength of (R. Zukowski and Dr. R. Gaze), 35
Ascidians : Size Relationship of Oocytes and their Nuclei in Two Species of (S. R. Venkatasubba Rao), 1454
Ascites Carcinoma Cells (Ehrlich) : Energy Compensation in the Crabtree Effect with (K. H. Ibsen, E. L. Coe and Dr. R. W. McKee), 1471
Ascites Tumour Cells : Micro-Electrode Penetration of (B. M. Johnstone), 411
Ascites Tumour Mice : Lithium Retention in /Shirley E. Simon, E. M. Trautner and D. A. Coats), 1128
Ascites Tumours : Possible Enzymic Mechanism for the Development of Resistance against Fluorouracil in (Dr. Peter Reichard and Ola Sköld, and Prof. George Klein), 939
Ascitic Tumours : Activity of 10-Hydroxydecenoic Acid from Royal Jelly against Experimental Leukaemia and (Prof. Gordon F. Townsend, Dr. Joseph F. Morgan and Dr. Barbara Hazlett), 1270
Ascorbic Acid in Germinating Green Gram : Glucose-*cyclo*-Acetoacetate as a Precursor of (Prof. M. C. Nath and M. L. Belkhode), 1258
Ascorbic Acid and similar Reductones : Oxidation of, by Nitrous Acid (Dr. C. A. Bunton and Prof. H. Dahn and Dr. Lotte Loewe), 163
Ascospore in *Neurospora crassa* : Linkage of Polygenes controlling Size of (B. T. O. Lee and J. A. Pateman), 698
Åselius, J., and others : Borides and Silicides of the Platinum Metals, 1318
Ash (Fly) : Forest Seedlings and Mycorrhiza Development on (A. Sobotka and J. Materna), 1066
Ashby, Sir Eric : University College, Ibadan, *review*, 137
Ashby, Dr. W. Ross : Appointed director of the Burden Neurological Institute, Bristol, 220 ; work of, 220, 510
  The Mechanization of Thought Processes (Habituation can be demonstrated in a mechanism without any detailed assumptions about its construction), 225
Asherson, G. L. : Elected to a Junior Fellowship by the Beit Memorial Trust, 1569
Ashes (Plant), and Animal Bones : Radioactivity of Soils, (Sir Ernest Marsden), 924
Ashton, Doris M. (Wyngaarden, Dr. James B., and) : Feedback Control of Purine Biosynthesis by Purine Ribonucleotides, 747
Ashton, Dr. E. H. : Natural Selection in Man, 159
Ashton, Dr. G. C. : β-Globulin Polymorphism and Early Foetal Mortality in Cattle, 404
Ashton, P. Shaw : Humid Tropics Vegetation (Tropical Peat-Swamps), 795
Asian Strains of Influenza Virus : New Inhibitor and Erythrocyte Receptor Substances for certain (Gy. Takátsy and K. Barb), 52
Askonas, Dr. Brigitte A., and others : Serum Antibody and γ-Globulin in Baby Rabbits after Transfer of Ribonucleoprotein from Adult Rabbits, 97
Aslib (Scottish Branch) : Annual General Meeting and Conference, 86
Aso, Kiyoshi (Watanabe, Toshiyuki, and): Isolation of Kojibiose from Honey, 1740
Aspartic and Glutamic Acids : Rapid Quantitative Horizontal Paper Chromatography at an Elevated Temperature—Determination of (Henry R. Roberts and Michael G. Kolor), 460
Aspects (Biological), of the Transmission of Disease—Report of the Institute of Biology Symposium (edited by C. Horton-Smith), *review* by Dr. C. W. Dixon, 1221
Aspects (Chemical), of the Production and Use of Grass (Dublin and District Section and the Agriculture Group of the Society of Chemical Industry Symposium on), 1783
Aspects (Immunological), of Allergic Disorders (British Society for Immunology and the British Association of Allergists Symposium on), 296
Aspects (New), of the Genetic Control of Industrial Melanism in the Lepidoptera (Dr. H. B. D. Kettlewell), 918
Aspects (Scientific and Technical), of Health Physics in Atomic Installations (European Nuclear Energy Agency and the Danish Atomic Energy Commission Symposium on), 934
Aspergillus niger : Inhibition of Growth and Respiration of *Ophiobolus graminis* var. *avenae* and, by Cystine (Elizabeth M. C. Turner), 1130
Aspergillus oryzae : Effect of Lytic Enzyme from *Bacillus circulans* and Chitinase from *Streptomyces* sp. on (Koki Horikoshi and Dr. Shigeji Iida), 186
Assay of Antibiotics : Micro-volume Drop-plate (Dr. M. R. S. Iyengar), 684
Assays (Microbiological) : A Source of Error in, attributable to a Bacterial Inhibitor in Distilled Water (S. A. Price and L. Gare), 838
Assimilation of Ammonia Nitrogen by Rumen Bacteria (A. T. Phillipson, Marjorie J. Dobson and T. H. Blackburn), 402
Assimilation of Organic Carbon by Bacteria : Role of Poly-β-Hydroxybutyric Acid in the (Prof. M. Doudoroff and Prof. R. Y. Stanier), 1440
Assimilation (Genetic), of Acquired Characters : Canalization of Development and (Prof. C. H. Waddington), 1654
Assistance : Technical (International Atomic Energy Agency), 864
Assistance (Technical), under the Baghdad Pact, 1367
Assistance Programmes : Technical (International Co-operation Administration), 1163
Association between Psychomotor Behaviour and Delinquency (H. S. Anthony), 343
Assortative Mating and Reciprocal Difference in the Blue–Snow Goose Complex (Dr. F. G. Cooch and Dr. J. A. Beardmore), 1833
Assortive Mating : Possibility of, in the Arctic Skua (P. O'Donald), 1210
Astapenko, P. D. : Antarctic Meteorology, 1504
Astbury, A. K. : The Black Fens, *review* by Dr. M. A. Morgan, 965
Astrolabe made by Regiomontanus on exhibition at the National Maritime Museum, 508
Astronautical Federation, International : Tenth Congress, 934
Astronomer's Universe (Prof. Bart J. Bok), *review* by Sir H. Spencer Jones, 1221
Astronomical Ephemeris, 1960 (D. H. Sadler), 1705
Astronomical Journal of the Academy of Sciences, U.S.S.R. : English translation to be published by the American Institute of Physics in co-operation with the National Science Foundation, under the title *Soviet Astronomy—AJ*, 1164
Astronomical Society, Royal : Gold Medal awarded to Dr. R. A. Lyttleton, 151
  Eddington Medal awarded to Dr. J. S. Hey, 151
  Election of Prof. R. O. Redman as president for 1959-60, 510
  Discussion on Turbidity Currents, 657
  Geophysical Discussion on the Automatic Reduction of Geophysical Data, 1166
Astronomical Society (Royal), and the British Glaciological Society : Geophysical Discussion on Characteristics of the Antarctic Ice-Sheet, 1575
Astronomy : Popularizing, 1019
  Report on the Progress of (J. H. Oort, F. T. Kerr and G. Westerhout), 1308
Astronomy (Radio) : Maser Observations in (L. E. Alsop, J. A. Giordmaine, C. H. Mayer and C. H. Townes), 223
Asymmetric Hydrolysis of Diethyl Acetamidomalonate by Chymotrypsin (Prof. Saul G. Cohen and Lucille Altschul), 1678
Atack, Dr. E. A. : Self-regulation in Living Systems (Knowledge of the Nervous System), 370
Atheromatosis (Rabbit) : Lack of Effect of Histidine on (Dr. G. G. Pinter and Dr. D. B. Zilversmit), 1272
Atheromatous Tissue (Normal and) : Liquid Crystals of Lipid in (G. T. Stewart), 871
Atherosclerosis (Experimental) : Disturbance in the Pattern of Serum Proteins in, and its Prevention (Prof. M. C. Nath, A. Saikia and B. I. Uppin), 894
Atherosclerotic Individuals : Composition of Lipids isolated from the Aorta, Coronary Arteries and Circulus Willisii of (Prof. C. J. F. Böttcher, F. P. Woodford, C. Ch. Ter Haar Romeny, E. Boelsma and C. M. Van Gent), 47
Atkins, Dr. W. R. G. : *Obituary* by Dr. F. S. Russell, 1228
Atlantic : A Lunar Radio Communication Link across the, 1500
Atlantic Coast of France : *Balanus tulipiformis* Ellis on the (B. S. Kisch), 341
Atlantic Eel Problem : A New Solution to the (Dr. Denys W. Tucker), 495
Atlantic Fisheries (North West), International Commission for the, and others : International Conference on Fishery Statistics, 1783

INDEX

Atlas Satellite (1958ζ) : The United States, 17
Atmosphere : Cosmic Dust in the (Dr. D. W. Parkin and W. Hunter), 732
Atmosphere at Heights between 200 km. and 400 km. : Density of the, from Analysis of Artificial Satellite Orbits (D. G. King-Hele), 1224
Atmosphere (Polar) Symposium, Oslo, 1956 : Part I, Meteorology Section (edited by R. C. Sutcliffe), Part 2, Ionospheric Section (edited by K. Weekes), *review* by James Paton, 279
Atmosphere (Upper) : Density of the (Dr. George Grimminger), 811
  Irregularities in the Density of the—Results from Satellites (D. G. King-Hele and D. M. C. Walker), 527
  Origin of Sodium and Lithium in the (Dr. T. M. Donahue), 1480
Atmosphere (Upper) Lithium Atoms responsible for the New Twilight Airglow at 6708 A. : Origin of (D. R. Barber), 384
Atmospheres (96,000) : Fusion Curve of Iron to—Temperature of the Earth's Core (Dr. H. M. Strong), 1381
Atmospheric Dust and Fluorescence (Dr. K. Przibram), 1048
Atmospheric Effects in the Orbital Acceleration of Artificial Satellites : Two (Dr. Luigi G. Jacchia), 526
Atmospheric Ice Nuclei : Volcanoes as a Source of (K. Isono, M. Komabayasi and A. Ono), 317
Atmospheric Pollen in relation to Land Use (H. A. Hyde), 1694
Atmospheric Research Group of Pasadena : Grant of 57,100 dollars from the National Science Foundation, to conduct field studies in cloud physics related to nucleation, hydrometeor development, electrification, and cloud dynamics, 1371
Atmospheric Temperatures, 864
Atmospheric Tides and Earth Satellite Observations (D. G. Parkyn), 1045 ; (G. V. Groves), 1047
Atmospheric Turbulence : Flying Locusts and (Dr. R. C. Rainey), 1367
Atomic Comforts, *review* by Prof. G. O. Jones, 1077
Atomic Electron Affinities (H. R. Johnson and Dr. F. Rohrlich), 244
Atomic Energy : Peaceful Uses of (Technical Films used at the Geneva Conference available from the United States Atomic Energy Commission), 721
Atomic Energy Agency (International): Pamphlet on Technical Assistance, 864
Atomic Energy Authority (United Kingdom) : Appointment of L. Grainger as head of the Metallurgy Division, 84
  Fuller use of microphotography in order to make atomic information more easily available, 365
  Appointment of Dr. Nyman Levin as director of the Weapons Group, 582
  Sir William Penney to succeed Sir John Cockcroft as member for research, 582
  Appointment of E. F. Newley as deputy director of the Weapons Group, 582
  The Nuclear Power Station at Chapelcross, 649
  Re-organization of the production and marketing of radioactive isotopes, 720
  Change in the organization of the, 861
  Appointment of D. W. Fry as director of the Atomic Energy Research Establishment, Winfrith, 861
  Appointment of Prof. F. A. Vick as deputy director of the Atomic Energy Research Establishment, Harwell, 861
  The Chapelcross Nuclear Power Station (J. C. C. Stewart), 1361
Atomic Energy of Canada, Ltd.,.and Queen's University, Kingston, Ontario : International Conference on Nuclear Structure, 1571
Atomic Energy Commission (Danish), (European Nuclear Energy Agency of the Organization for European Economic Co-operation and the) : Symposium on the Scientific and Technical Aspects of Health Physics in Atomic Installations, 934
Atomic Energy Commission (French) : The Nuclear Research Centre, Grenoble, 858
Atomic Energy Commission (United States) : Charges for Uranium-233 and Plutonium, 84
  Grant of 25,421 dollars to Prof. W. E. Wallace (University of Pittsburgh), to continue an investigation of the application of chemical thermodynamics to study the formation of metallic alloys, 86
  Training Courses at the Shippingport Atomic Power Station, 153
  SPERT III achieves criticality at the National Reactor Testing Station, Idaho Falls, 365
  Grants for Training Courses, 437
  Availability of Technical Films used at the Geneva Conference on the Peaceful Uses of Atomic Energy, 721
  Criticality reached by the Transient Reactor Test Facility (TREAT), 862
  Grants to American Colleges and Universities for Nuclear Training in the Biological Sciences, 1091
  Grants for Training in Radioisotope Technology, 1641
  Replacement sheets for Sullivan's Trilinear Chart of Nuclides, 1719
Atomic Energy Research Establishment, Harwell : Second Course at the Harwell Reactor School on the Control and Instrumentation of Reactors, 153
  Course for Senior Technical Executives in Industry, at the Harwell Reactor School, 224
  Appointment of Prof. F. A. Vick as deputy director, 861
  Courses at the Harwell Reactor School, 1643
Atomic Energy Research Establishment, Winfrith : Appointment of D. W. Fry as director, 861
Atomic Installations : The Scientific and Technical Aspects of Health Physics in (European Nuclear Energy Agency and the Danish Atomic Energy Commission Symposium on), 934
Atomic Lithium : Electron Affinity of (E. Holøien), 173
Atomic Mechanisms of Fracture (U.S. National Academy of Sciences, the U.S. National Science Foundation, the Office of Naval Research and the Air Force Office of Scientific Research International Seminar on), 154
Atomic Motions (Molecular and), in Solids and Liquids : The Study of, by Radiofrequency Methods (British Radio Frequency Spectroscopy Group and the Groupement AMPERE Joint Meeting on), 652
Atomic Physics and Human Knowledge (Dr. Niels Bohr), *review* by Prof. W. H. McCrea, 1218
Atomic Power Company, Japan : Construction of a 150-MW. Atomic Power Station, 1019
Atomic Power Station for Japan, 1019
Atomic Power Station (Shippingport) : Training Courses at the (United States Atomic Energy Commission), 153
Atomic Reactor : First Hungarian, 1162
Atomic Weight : Isotopic Composition of Boron and its (W. J. Lehmann and I. Shapiro), 1324
Atomization (Heterogeneous), of Hydrogen and Oxygen (Dr. D. Brennan and P. C. Fletcher), 249
Atoms (Upper-Atmosphere Lithium), responsible for the New Twilight Airglow at 6708 A. : Origin of (D. R. Barber), 384
Atoms and Molecules (Free) : Radiofrequency Spectroscopy of (Radiofrequency Spectroscopy Group Autumn Meeting on), 1502
Aucuba Mosaic Virus (Tomato) : Persistence of, in Dried Leaf Tissue (Prof. John Caldwell), 1142
Audio-direction Finding in the Porpoise (*Phocaena phocaena*), (W. H. Dudok van Heel), 1063
Audrieth, Prof. Ludwig F. : Appointed Science Officer in the American Embassy in Bonn, 15
Audus, Prof. L. J. : Experimental Approaches to the Problems of Growth and Form in Plants (Mechanism of Correlation in Plant Development), 584
Auerbach, Dr. C. : Radioactive Fall-out, 1773
Augustin, R. : Immunological Aspects of Allergic Disorders (Allergens and other Pollen Antigens), 296
Augustin, R., and others : Immunological Aspects of Allergic Disorders (Immunochemistry of *Cladosporium*), 297
Aurora : Effects of the, on Radio Reception, 579
  The Samoan Artificial (Dr. H. Elliot and J. J. Quenby), 810
Aurorae (Sub-Visual), and Radio Noise Bursts on 4·6 kc./s. : Simultaneous Occurrence of (R. A. Duncan and G. R. Ellis), 1618
Aurorae (Sunlit): Rotational Structure of the 3914 A. N_2^+ Band in (Dr. D. M. Hunten, H. J. Koenig and Prof. A. Vallance Jones), 453
Auroral Echoes : Movement of, and the Magnetic Disturbance Current System (R. S. Unwin), 1044
Auroral Isochasms (Dr. Bengt Hultqvist), 1478
Austin, Dr. C. R. : Entry of Spermatozoa into the Fallopian-Tube Mucosa, 908
Austin, E. E., and others : Upper Air Temperature over the World (Meteorological Office, Geophysical Memoir No. 101), 864
Austin, W. H., and others : Effect of Dietary Phytate on Faecal Absorption of Radioactive Ferric Chloride, 691
Australia : Scientific Research in, 155
Australia, Africa and England : Precambrian Coelenterata from (Dr. M. F. Glaessner), 1472
Australian Academy of Science (under the auspices of the International Union of Biochemistry) : Symposium on Haematin Enzymes, 1571
Australian Chemical Institute, Royal : H. G. Smith Memorial Medal awarded to Prof. S. J. Angyal, 794
Australian Commonwealth Scientific and Industrial Research Organization : Ninth Annual Report (1956-57), 155
  Chemical Research Laboratories, 228
  Appointment of Dr. I. W. Wark as the first director of the Chemical Research Laboratories, 228
  Appointment of Dr. A. L. G. Rees as chief of the new Division of Chemical Physics, 228
  Appointment of Dr. K. L. Sutherland as chief of the new Division of Physical Chemistry, 228
  Rural Research, 228
  Annual Report for 1957-58 of the Division of Electrotechnology, 1781
Australian Defence Standards Laboratories : Annual Report for 1956, 581
Australian Museum Magazine : Vol. 12, No. 12, devoted almost entirely to New Guinea, 1368
Australian National University : Appointment of Dr. A. G. Ogston to the chair of physical biochemistry, 151
  To set up a Field Station for Astronomy, 1091
Australian and New Zealand Association for the Advancement of Science : Future of the, 1303
Australian (South) Museum : *Records* of the, Vol. 13, No. 2, 1092
Australian (Western) Wildflowers : How to Know (Dr. William E. Blackall and Dr. Brian J. Grieve), Part 2, A Key to the Flora of the Temperate Regions of Western Australia, *review* by V. S. Summerhayes, 1628
'Australopithecine' Scoop from Herefordshire (Prof. Raymond A. Dart). 844
Automatic Computing Engine at the National Physical Laboratory (J. H. Wilkinson and D. W. Davies), 22
Automatic Control Theory : Basic (Prof. Gordon J. Murphy), *review* by M. J. Somerville, 211
Automatic Programming of Digital Computers (Brighton Technical College Residential Working Conference on), 438, 1779
Automatic Reduction of Geophysical Data (Royal Astronomical Society Geophysical Discussion on), 1166
Automatically Operating, Coulometric Titration Method for continually Measuring Small Amounts of Water in Fluids (E. Barendrecht), 1181
Automation, Computation and Control : Handbook of (edited by Eugene M. Grabbe, Simon Ramo and Dean E. Wooldridge), Vol. I, Control Fundamentals, *review* by P. H. Hammond, 1556
Autoradiograms for Electron Microscopy : Preparation of (R. T. O'Brien and L. A. George, II.), 1461
Autoradiographic Method for distinguishing Samples labelled with Phosphorus-32 and Sulphur-35 (Dr. W. G. Duncombe), 319
Autoxidation (Alkaline), of Cellulose at Low Alkali Concentration : Catalytic Action of Copper in the (R. I. C. Michie and Dr. S. M. Neale), 534
Autumn Colour and Leaf-fall of Deciduous Woody Plants : Effect of Gibberellic Acid on Development of (Dr. P. W. Brian, J. H. P. Petty and P. T. Richmond), 58
Auxins : Action of, on *Acetabularia* and the Effect of Enucleation (Prof. Kenneth V. Thimann and Dr. Kurt Beth), 946
  Control of Leaf Senescence by (Daphne J. Osborne), 1459
  Effects of, on Membrane Permeability and Pectic Substances in Bean Endocarp (J. A. Sacher and K. T. Glasziou), 757
  Effects of Kinetin, Gibberellic Acid and certain, on the Development of Shoot Buds on the Protonema of *Pohlia nutans* (Dr. G. C. Mitra and Dr. A. Allsopp), 974
Auxins and Nucleic Acid Synthesis in Coleoptile Tissues : Relationship between (B. B. Biswas and S. P. Sen), 1824
Availability of Scientific Information, 135
Available Energy in Thermodynamics, *review* by R.W. Haywood, 353
Average Length of Working Life, 1780

Avery, Dr. Eugene C. (Smaller, Dr. Bernard, and) : Radiation Protection and Free Radicals, 539

Avian Folklore, *review* by M. C. Burkitt, 1422

Aviation : Agricultural, Vol. I, No. I (European Agricultural Aviation Centre), 720

Aviation Medicine—Selected Reviews (edited by Clayton S. White, W. Randolph Lovelace, II, and Frederic G. Hirsch), *review*, 1291

Aviation Psychology in Western Europe and a Report on Studies of Pilot Proficiency Measurement (Western-European Association for Aviation Psychology), 1092

Aviation Psychology, Western-European Association for : Publication No. I, Aviation Psychology in Western Europe and a Report on Studies of Pilot Proficiency Measurement, 1092

Avoirdupois Pound for Science and Technology : The Yard and the, 80

Axelrad, A. A., and others : A Cytopathogenic Agent from a Mammary Tumour in a *C3H* Mouse that produces Tumours in Swiss Mice and Hamsters, 1535

Axelrod, Dr. Julius, and others : Enzymatic N-Methylation of Histamine, 680

Axon Membrance (Squid) : Excitation of the, in Isosmotic Potassium Chloride (Dr. John W. Moore), 265

Ayer, Prof. A. J. : Appointed to the Wykeham chair of logic in the University of Oxford, 792 ; work of, 792

Aylmore, L. A. G., and Quirk, Dr. J. P : Swelling of Clay–Water Systems, 1752

Azaserine (*o*-Diazoacetyl-L-serine) : Effect of, on the Pyridine Nucleotide Levels of Mouse Liver (Stuart A. Narrod, Thomas A. Langan, jun., Prof. Nathan O. Kaplan and Abraham Goldin), 1674

Azeotropic Data : Physical and—Hydrocarbons and Sulphur Compounds boiling below 200° C. (G. Claxton), *review* by Dr. B. A. Rose, 709

Azide (Thallous) : Absorption Spectra and Associated Photoconductivity of Pure and Decomposed Crystals of (B. L. Evans and A. D. Yoffe), 1241

Azo Dye (Carcinogenic) : Prevention of Adaptive Formation of Tryptophan Peroxidase by a (Dr. Silvio Fiala and Anna E. Fiala), 1532

Azotobacter : Production of Acid from Arabinose and Xylose by Strains of (Vagn Jensen), 1536

BABICKY, A., and others : Labelling of Radiographic Contrast Media with Iodine-131, 1474

Babies with Multiple Malformations : Co-existence of the Embryonic (Third Normal) Haemoglobin Fraction with Erythroblastosis in the Blood of Two Full-term New-born (Prof. I. Halbrecht, Ch. Klibanski and F. Bar Ilan), 327

Baby Rabbits : Serum Antibody and γ-Globulin in, after Transfer of Ribonucleoprotein from Adult Rabbits (Dr. Miroslava Hrubešova, Dr. Brigitte A. Askonas and Dr. J. H. Humphrey), 97

Bacharach, A. L. : Elected president of the Nutrition Society, 1643

Bacigalupo, G., and others : Influence of L-3', 5, 3-Triiodòthyronine on the Oxidative Phosphorylation of Tumour Mitochondria, 1534

Bacillus anthracis : Inactivation of Spores of, by γ-Radiation (T. Horne, G. C. Turner and A. T. Willis), 475

Bacillus cereus growing synchronously out of Spores : Pattern of Synthesis of Deoxyribonucleic Acid in (Dr. I. Elizabeth Young and Prof. Philip C. Fitz-James), 372

Bacillus cereus and *Bacillus megaterium* : Differences in Cyst(e)ine Content between Vegetative Cells and Spores of (Vladimír Vinter), 998

Bacillus circulans : Effect of Lytic Enzyme from, and Chitinase from *Streptomyces* sp. on *Aspergillus oryzae* (Koki Horikoshi and Dr. Shigeji Iida), 186

Bacillus megaterium: Differences in Cyst(e)ine Content between Vegetative Cells and Spores of *Bacillus cereus* and (Vladimír Vinter), 998

Back Grant of the Royal Geographical Society awarded to David Stratton, 292

Background (Family), and Educational Progress in Scotland : Intelligence, *review* by Jean Floud, 493

Background Gamma-Radiation : Increase in, and its Correlation with Iodine-131 in Milk (Measurements at Leeds following the Windscale Reactor Accident, (Prof. F. W. Spiers), 517

Backhurst, Dr. J. D., and others : Determination of the Yields of Molecular Hydrogen Peroxide in the Radiolysis of Water labelled with Oxygen-18, 176

Bäckström, Prof. Matts : Kältetechnik, zweite Auflage, bearbeitet und ins Deutsche übertragen von Dr. Eduard Emblik, *review* by Dr. K. Mendelssohn, 1150

Bacon, Dr. G. E., and Dyer, R. F. : Neutron Diffraction at a High-Flux Reactor, 35

Bacq, Prof. Z. M., and others : Comparative Sensitivity to Radiation of Seeds from a Wild Plant grown on Uraniferous and Non-Uraniferous Soils, 1449

Bacteraemia : Leucocytosis in Response to, as a Feature of the Acute Radiation Syndrome in the Plaice (A. Preston), 832

Bacteria : Detection of Sialic Acid in various *Escherichia coli* Strains and in other Species of (Prof. Guy T. Barry), 117

  Linear Transfer of a Potentially Mutant State in (Dr. F. Kaudewitz), 871

  Non-Flagellar Appendages of (Dr. Charles C. Brinton, Jun.), 782

  Role of Poly-β-Hydroxybutyric Acid in the Assimilation of Organic Carbon by (Prof. M. Doudoroff and Prof. R. Y. Stanier), 1440

  Synthesis of Deoxyribonucleic Acid during the Division Cycle of (M. Schaechter, M. W. Bentzon and Prof. O. Maaløe), 1207

Bacteria are given Large Pulses of Radiation : Modification of the Oxygen Effect when (D. L. Dewey and Dr. J. W. Boag), 1450

Bacteria, Protozoa and Diet : A Relationship between some, in Early Weaned Calves (J. Margaret Eadie, Dr. P. N. Hobson and S. O. Mann), 624

Bacteria (Airborne) : Chloramphenicol and the Survival of (S. J. Webb), 1072

Bacteria (Marine) : Adaptation of, to Growth in Media lacking Sodium Chloride (Prof. D. B. Pratt and G. Waddell), 1208

Bacteria (Rumen) : Assimilation of Ammonia Nitrogen by (A. T. Phillipson, Marjorie J. Dobson and T. H. Blackburn), 402

Bacteria (Soil) : Decomposition of Anionic Surface-Active Agents by (Dr. F. A. Skinner), 548

Bacteria-free Culture-filtrate of *Vibrio cholerae* : Enterotoxicity of (Prof. S. N. De), 1533

Bacterial Action in Pond-stored Logs (Eric L. Ellwood and Barton A. Ecklund), 1206

Bacterial Cytoplasm: Effect of Drugs upon Components of (Dr. S. Dagley and J. Sykes), 1608

Bacterial Endospores : Dependence of the Heat Resistance of, on their Dipicolinic Acid Content (Brooks D. Church and Harlyn Halvorson), 124

Bacterial Inhibitor in Distilled Water : A Source of Error in Microbiological Assays attributable to a (S. A. Price and L. Gare), 838

Bacterial Mutants : Production of, with Nitrous Acid (Dr. Fritz Kaudewitz), 1829

Bacterial Mutants of Increased Sensitivity to 'Aminopterin' : Selection of (Dr. Charles A. Nichol), 550

Bacterial Neuraminidase (Receptor-destroying Enzyme) : Purification of (G. L. Ada and E. L. French), 1740

Bacterial Population Studies in the Chemostat, *review* by Dr. A. C. R. Dean, 424

Bacterial Populations maintained in the Chemostat : The Dynamics of (Hermann Moser), *review* by Dr. A. C. R. Dean, 424

Bacterial and Testicular Hyaluronidase (Prof. Ernst Báráany, Lennart Berggren and Lennart Juhlin), 265

Bacteriological, Chemical and Biological Examination of the London Waters for the Years 1955-56 : Thirty-seventh Report on the Results of the (E. Windle Taylor), 798

Bacteriology at Adelaide, 1716

Bacteriology (Applied), Society for : Symposium on Lactobacilli, 1234

Bacteriophage : Neutralization of, by Normal Serum (Andre J. Toussaint and Louis H. Muschel), 1825

Bacteriophage Enrichment in a Liquid Two-Phase System with Subsequent Treatment with 'Freon' 113 (Dr. G. Frick and Dr. P. A. Albertsson), 1070

Bacterium with Fungicidal Activity (W. E. Crawley and D. C. Dodd), 63

Bacterium (A Gram-negative Sporing), from the Rumen (Dr. P. N. Hobson and M. R. Purdom), 904

Bagchi, D. (Basu, T. N., and) : The Nature of Coal (Physical Methods of Studying the Constitution of Coals), 1438

Baghdad Pact : Technical Assistance under the, 1367

Bagnall, Dr. K. W. : Chemistry of the Rare Radioelements—Polonium–Actinium, *review* by G. R. Hall, 962

Bailey, Dr. G. L. J. : Elected president of the Institute of Metals, 1024

  Appointed superintendent of the Development and Research Department Laboratory of the Mond Nickel Co., Ltd., Birmingham, 1432 ; work of, 1432

Bailey, Kenneth, and others (edited by) : Advances in Protein Chemistry. Vol. 12, *review* by Dr. M. F. Perutz, 1290

Bailey, L. : Parasitology (Resistance of Honeybees to Epidemics of a range of Parasites), 1506

Bailey, R. : Facultative Parasitism and Dietary Change in *Harmolita hyalipenne* Walker, 341

Bailey, R., and others : Canadian Caesium-Beam Standard of Frequency, 575

Bainbridge, Prof. K. T. : Apparatus and Applications of Mass Spectroscopy, *review*, 638

Bair, W. J., and others : Induction of Lung Tumours by Radioactive Particles, 408

Baird, Robert Douglas : Appointed a director of Baird and Tatlock (London), Ltd., and of Hopkin and Williams, Ltd., 794

Baird and Tatlock (London), Ltd., and Hopkins and Williams, Ltd. : Appointment of Robert Douglas Baird as a director, 794

Baird-Parker, A. C. (Davis, Dr. G. H. G., and) : Cell-Wall Composition of *Leptotrichia* spp., 1206

Bajusz, S., and others: Inhibitory Action of Amino-Acid Esters on the Production of Extracellular Amylase by *Penicillium chrysogenum*, 477

Bak, Prof. B. : Chemistry and Quantum Chemistry, 158

Baker, E. Alan, and Foskett, D. J. : Bibliography of Food—a Select International Bibliography of Nutrition, Food and Beverage Technology and Distribution, 1936-56, *review* by Dr. Magnus Pyke, 351, 582

Baker, Prof. J. F. : Science and Technology in the University of Bristol—Opening of Queen's Building, 217

Baker, Dr. John R. : A. or $m\mu$ in Electron Microscopy, 416

Baker, John William : Electronic Theories of Organic Chemistry, *review* by Dr. R. I. Reed, 777

Baker, R. G. : Elected president for 1960-61 of the Institution of Mining Engineers, 1716 ; work of, 1716

Baker's Yeast : Utilization of Inorganic Sulphate by (Dr. A. Kleinzeller, A. Kotyk and L. Kováč), 1402

Balance Trials with Magnesium-28 in Sheep (Alexander C. Field), 983

Balanced Education : The Need for a, 1075

Balanus amphitrite var. *stutsburi* Darwin : Abnormal Development of the Basis in (Dr. H. G. Stubbings), 1282

Balanus tulipiformis Ellis on the Atlantic Coast of France (B. S. Kisch), 341

Balázs, V., and others : Changes produced in Serum Lipoproteins of Dogs by Cellulose containing Methyl Groups, 1119

Balch, Dr. C. C. : Function of the Rumen (Structure of the Ruminant Stomach and the Movement of its Contents), 1644

Baldwin, W. F., and Salthouse, T. N. : Oxygen Deficiency and Radiation Damage in the Insect *Rhodnius*, 974

Balescu, R. : Problems of Collective Motion in Physics (Gaseous Plasmas), 866

Balfour, Dr. J. G., and others : Nuclear Fuel Cycles (Perturbations due to Fuel Cycles), 1647

Balfour, Dr. W. E., and others : Changes in the Secretion of 20α-Hydroxy-pregn-4-en-3-one by the Adrenal Gland of Young Calves, 467

Balfour-Browne, Prof. Frank : British Water Beetles, Vol. 3, *review* by Dorothy J. Jackson, 1420

Ball, F. K. : Antarctic Meteorology, 1503

Ball Milling : Release of Fixed Ammonium from the Soil by (P. M. McDonnell, Prof. F. J. Stevenson and Dr. J. M. Bremner), 1414

'Ball' Mills : Grinding at Super-Critical Speeds in (Dr. H. E. Rose and M. D. Trbojević), 813

Ballance, P. E. (Crombie, Dr. W. Mary, and) : Synthesis of Long-Chain Fatty Acids from 2-^{14}C-Acetate and ^{14}C-Glucose in *Trichoderma viride*, 1195
Ballantyne, Dr. A. M. : Elected a Fellow of the American Institute of the Aeronautical Sciences, 368
Ballay, Dr. Marcel : *Obituary*, 647
Ballio, A., and others : Penicillin Derivatives of *p*-Aminobenzylpenicillin, 180, *erratum*, 224
Baló, Prof. J., and others : Effect of 1,6-Di-(2-Bromoethylamino)-1,6-Dideoxy-D-Mannitol Dihydrobromide on Tumours of Laboratory Animals, 395
Balogh, Dr. Johan : Lebensgemeinschaften der Landtiere, zweite Auflage, *review* by A. Macfadyen, 966
Balsley, J. R., and others : Magnetostriction and Palaeomagnetism of Igneous Rocks, 1318
Bamboos of Malaya (R. E. Holttum), 1169
Bamboos and Nutmegs, 1169
Bamford, Dr. C. H., and others : The Kinetics of Vinyl Polymerization by Radical Mechanisms, *review* by Prof. C. E. H. Bawn, 637
Bananas: Vascular Wilt Disease of, caused by *Fusarium oxysporum* f. *cubense* (R. H. Stover), 1782
Band Spectra (Diatomic) : Changes in Transition Probability due to the Interaction of Rotation and Vibration in (R. C. M. Learner and Dr. A. G. Gaydon), 242
Bands and Lines (New), in the Twilight Sky Spectrum (I. A. Khvostikov and T. G. Megrelishvili), 811
Banks, B. E. C., and others : Glutamic–Aspartic Transaminase of Pig Heart Muscle, 1187
Banks, Dr. C. J. : Proceedings of a Symposium on Insect and Food-plant, *review*, 1767
Banks, Sir Joseph : Correspondence of, *review* by Dr. W. B. Turrill, 1353
Banks Letters : The—a Calendar of the Manuscript Correspondence of Sir Joseph Banks preserved in the British Museum, the British Museum (Natural History), and other collections in Great Britain (edited by Warren R. Dawson), *review* by Dr. W. B. Turrill, 1353
Banks, Dr. R. E., and others : Thermal Reactions of Highly Fluorinated *Cyclo*hexadienes, 586
Bannerman, Dr. David A., and Bannerman, W. Mary : Birds of Cyprus, *review* by Sir Landsborough Thomson, 967
Bannerman, W. Mary (Bannerman, Dr. David A., and) : Birds of Cyprus, *review* by Sir Landsborough Thomson, 967
Barabás, jun., Z. : An Induced Mutant in *Triticum carthlicum* with the Diagnostic Feature of *T. vavilovi*, 1349
Bárány, Prof. Ernest, and others : Bacterial and Testicular Hyaluronidase, 265
Barb, K. (Takátsy, Gy., and) : New Inhibitor and Erythrocyte Receptor Substances for certain Asian Strains of Influenza Virus, 52
Barb, Dr. W. G., and others : The Kinetics of Vinyl Polymerization by Radical Mechanisms, *review* by Prof. C. E. H. Bawn, 637
Barber, D. R. : Singing Pattern of the Common Chaffinch, *Fringilla coelebs* Linn., 129
  Origin of Upper-Atmosphere Lithium Atoms responsible for the New Twilight Airglow at 6708 A., 384
Barber, Dr. H. J. : Speaking on the motion 'That the Education of our Future Rulers should be primarily in the Sciences rather than the Humanities', 1236
Barbier, Dr. G. : Phosphates and Organic Substances in Nitrogen Deficiency, 513
Barbiturate Nystagmus and the Mechanisms of Visual Fixation (C. Rashbass), 897
Barbiturates : Identification of (Dr. A. S. Curry), 1052
Barbour, Dr. A. K., and others : Thermal Reactions of Highly Fluorinated *Cyclo*hexadienes, 586
Barclay, A. : Retirement as keeper of the Department of Chemistry in the Science Museum, London, 224
Bardos, Thomas J., and others : 'Dual Antagonists' ; Alkyl N-(*bis*-(ethylenimido)phosphoro)-carbamates ; a New Series of Anti-Tumour Agents, 399
  Anti-Tumour Activity of 5-Mercaptouracil, 612
Barendrecht, E. : An Automatically Operating, Coulometric Titration Method for continually Measuring Small Amounts of Water in Fluids, 1181
Barer, Dr. R. : Physical and Chemical Exploration of the Cell, *review*, 1355
Bargmann, Prof. Wolfgang : Elected a member of the Anatomy Section of the Deutsche Akademie der Naturforscher Leopoldina, 652
Barker, Dr. H. Albert : Awarded the Neuberg Medal of the American Society of European Chemists, 1304
Barker, Dr. S. A., and others : Effects of Gamma-Radiation on some Carbohydrates, Hydroxyacids and Amino-Acids in Aqueous Solutions, 376
  Identification of 10-Hydroxy-Δ^2-decenoic Acid in Royal Jelly, 996
Barley : Spraying of, with 2,4-Dichlorophenoxyacetic Acid (E. L. Leafe), 621
  Varietal Resistance to Spray Damage in (J. Desmond Hayes), 551
Barley Leaves : Amino-Acid Composition of the Proteins of, in relation to the Mineral Nutrition and Age of Plants (Dr. B. P. Pleshkov and Dr. L. Fowden), 1445
Barley Mash fermented by the Amylo Process : Unfermentable Sugars in (Hideo Ono and Michio Dazai), 1055
Barley Roots : Effect of Phosphorylated Methyl-naphthohydroquinones on the Response to Radiation in (A. D. McKelvie), 1194
Barlow, Dr. H. B. : The Mechanization of Thought Processes (The Coding of Signals in Sensory Mechanisms), 225
Barlow, Prof. H. E. M. : Long-Distance Transmission by Wave-Guide, 727
Barlow, J. : Relaxation Processes (Ultrasonic Techniques to determine the Shear Mechanical Impedance of Lubricating Oils), 584
Barnard, Cyril : *Obituary* by Dr. W. R. Bett, 1159
Barnard, Dr. J. A., and Hughes, Dr. H. W. D. : Analysis of Light Hydrocarbon Gas Mixtures, 250
  Analysis of Hydrocarbons, 744
Barnes, Dr. H. : Elected a Fellow of the Royal Society of Edinburgh, 719
Barnes, M. J., and others : Presence of Griseofulvin in Hair of Guinea Pigs after Oral Administration, 256
Barnes, R. S., and Cottrell, Prof. A. H. : Interfacial Phenomena (Annealing of Radiation Damage in Copper produced by Bombardment with α-particles), 1099
Barnett, S. A. : Darwinism and the Study of Society, 1564
Barr, W. : Elected president of the Iron and Steel Institute, 1234
Barrer, Prof. R. M. : Validity of Clapeyron's Equation for Phase Equilibria involving Clathrates, 463
Barrett, J. : Detection of Hydroxyl Groups in Porphyrins and Chlorins, 1185
Barrier in the Spread Eastwards of Haemoglobin C : The River Niger as a —a Survey of Haemoglobins in the Ibo (Dr. H. Lehmann and Dr. C. Nwokolo), 1587
Barrs, H. D. (Weatherley, Dr. P. E., and) : A Climatological Wind Tunnel, 94
Barry, Prof. Guy T. : Detection of Sialic Acid in various *Escherichia coli* Strains and in other Species of Bacteria, 117
Bartholomew, Prof. J. W., and others : A Correlation between Iodine Permeability and the Gram Characteristic of Cells, 123
Barton, A. D. (Laird, Anna Kane, and) : Cell Growth and the Development of Tumours, 1655
Bartonellas : Characteristics of the, *review* by Dr. A. Lwoff, 207
Bartonellen : Morphologische, Biologische und Serologische Eigenschaften der (Dr. Reinhard Wigand), *review* by Dr. A. Lwoff, 207
Bartram, William: The Travels of (edited by Francis Harper), naturalist's edition, *review* by Dr. L. Harrison Matthews, 1006
Bartram's America : John and William (edited by Helen Gere Cruickshank), *review* by Dr. L. Harrison Matthews, 1006
Barua, D. (Fauconnier, B., and) : Increase of Viral Haemagglutinability of Red Cells of the Mouse after Treatment with Formalin, 629
Basalts (Cretaceous), of Madagascar : Remanent Magnetism of the (Dr. A. Roche and L. Cattala), 1049
Bashir, M. : The Role of the Scholar in Society, 1773
Basic Automatic Control Theory (Prof. Gordon J. Murphy), *review* by M. J. Somerville, 211
Basic Biodynamics (E. J. Kempf), 933
Basic Chromosome Numbers (Two New), in the Musaceae (K. Shepherd), 1539
Basic Physics (Dr. A. R. Meetham), *review* by S. Weintroub, 354
Basic Problems in Propulsion (Advisory Group for Aeronautical Research and Development of NATO Discussion on), 1094
Basic Substances as Synergists for Fat Antioxidants (H. S. Olcott and E. J. Kuta), 1812
Basic and Clinical Research of the New Antibiotic, Kanamycin (Maxwell Finland, and 93 other authors), 1570
Basinki, S. J. (Bland, J. A., and) : Crystal Symmetry of Struvite (Guanite), 1385
Basis in *Balanus amphitrite* var. *stutsburi* Darwin : Abnormal Development of the (Dr. H. G. Stubbings), 1282
Basis (Chemical), for the Classification of Glume Colour in Nigerian Cultivated Sorghums (W. R. Stanton, T. B. Miller and D. L. Curtis), 807
Basis (An Enzymatic), for the Acceleration of Ciliary Activity by Negative Air Ions (Prof. A. P. Krueger and Richard F. Smith), 1332
Basis (Neurological), of Behaviour : Ciba Foundation Symposium on the (edited by G. E. W. Wolstenholme and Cecilia M. O'Connor), (in commemoration of Sir Charles Sherrington, 1857-1952), *review* by Dr. P. B. Bradley, 954
Basis (Physical), for Electrical Engineering (Prof. Thomas L. Martin, Jr.), *review* by Dr. D. A. Bell, 707
Basis (Scientific), of Land Planning in the Tropics (Prof. L. Dudley Stamp), 20
Baskett, Prof. R. G. : Appointed director of the National Institute for Research in Dairying, 294, 365 ; work of, 365
Basolo, F. (Jensen, A., and) : Co-ordination Chemistry (Kinetics of the Substitution Reactions of *bis*cyclopentadienyl Titanium Dihalides), 1784
Bassett, G. A. : Interfacial Phenomena (Nucleation, Orientation and Growth of Vacuum-deposited Metal Films), 1097
Bastenie, Prof. P. A. (Ermans, A. M., and) : Rate of Exchange of Phosphate in Red Blood Cells—Effect of Thyroid Hormones, 679
Bastiansen, Prof. O. : Chemistry and Quantum Chemistry, 158
Basu, T. N., and Bagchi, D. : The Nature of Coal (Physical Methods of Studying the Constitution of Coals), 1438
'Bat Erosion' at Niah Great Caves (Tom Harrisson and Lord Medway), 971
Batchelor, F. R., and others : Penicillin Derivatives of *p*-Aminobenzylpenicillin, 180, *erratum*, 224
  Synthesis of Penicillin—6-Aminopenicillanic Acid in Penicillin Fermentation, 257
Bate-Smith, Dr. E. C. : Chemistry of Condensed Tannins (Formation of Condensed Tannins in Plants), 1169
Bates, Prof. D. R. : Space Research (Experimental Results and Theoretical Considerations relevant to an Understanding of the Atmosphere above 100 km.), 362
Bathyscaphe *F.N.R.S.* III (Dr. F. S. Russell), 1651
Bats and Men : Listening in the Dark, the Acoustic Orientation of (Prof. Donald R. Griffin), *review* by Prof. R. J. Pumphrey, 1554
Battan, Louis J., and others : Grant of 161,800 dollars from the National Science Foundation, to study the physics of clouds and of cloud modification, 1371
Battelle Memorial Institute : New laboratory for research on plutonium, 720
Battey, Edward W. (compiled by) : Instrument Encyclopedia, *review* by Dr. C. A. Taylor, 1768
Bawden, Prof. F. C. : Viruses, Genes and Antigens, *review*, 636
Bawden, Prof. F. C., and Kleczkowski, A. : Photoreactivation of Nucleic Acid from Tobacco Mosaic Virus, 503
Bawn, Prof. C. E. H. : Polymer Chemistry, *review*, 637
Bayley, Dr. F. J. : An Introduction to Fluid Dynamics, *review* by J. L. Stollery, 421
Bayley, H. G. : Gelatin as a Photo-elastic material, 1757
Bayman, B. : Problems of Collective Motion in Physics (The Bohr-Mottelson Explanation of the 'Energy-Gaps' found in Nuclei), 866
B.B.C. : Appointment of C. L. Boltz as Science Correspondent in the News Division, 1231
  Annual Grant of £5,000 for three years to the Council for Nature, for the establishment of an Intelligence Unit, 1231
  Reith Lectures (Prof. A. C. B. Lovell), *review* by Dr. R. A. Lyttleton, 1624
Beacon, Seward E. : Explosion of Transition Metal Co-ordination Compounds, 38
Beadle, B. E. : Hypersonic Flow, 1095
Beale, Dr. G. H. : Elected a Fellow of the Royal Society, 860

Beam, Dr. Walter R. : Appointed head of the Department of Electrical Engineering at Rensselaer Polytechnic Institute, Troy, N.Y., 1164
Bean Endocarp : Effects of Auxins on Membrane Permeability and Pectic Substances in (J. A. Sacher and K. T. Glasziou), 757
Bean (Broad) Seeds : Effect of Light on Maturing (Dr. G. R. Lane and R. D. Butler), 1063
Beans (Black), *Phaseolus vulgaris* : Purification of a Toxic Phytohaemagglutinin from (Dr. Werner G. Jaffé and Karl Gaede), 1329
Bear Island Cod—Migrations and Movements (G. C. Trout), 1100
Beardmore, Dr. J. A. (Cooch, Dr. F. G., and) : Assortative Mating and Reciprocal Difference in the Blue–Snow Goose Complex, 1833
Beardslee, Prof. David C., and Wertheimer, Prof. Michael (selected and edited by) : Readings in Perception, *review* by Prof. R. W. Pickford, 1625
Beare, Prof. W. : Speaking on the motion 'That the Education of our Future Rulers should be primarily in the Sciences rather than the Humanities', 1235
Beattie, J. M., and others (edited by) : Trace Elements—Proceedings of the Conference held at the Ohio Agricultural Experiment Station, 1957, *review* by Dr. E. J. Hewitt, 1009
Beatty, Iva M., and Magrath, Dr. D. I. : Biochemistry of Lombricine—Synthesis of DL- and L-Lombricine, 591
Beatty, Iva, M., and others : Biochemistry of Lombricine—Occurrence of D-Serine in Lombricine, 591
Beberman, Prof. Max : An Emerging Programme of Secondary School Mathematics (Inglis Lecture for 1958), 1366
Beck, M. T. : Co-ordination Chemistry (Work on Catalysis in Hungary), 1785
Beck, Prof. P. A., and others : Low-temperature Specific Heats of Body-centred Cubic Chromium–Iron and Chromium–Manganese Alloys, 315
Becker, E. L., and others : Enzymic Nature of the Serum Globulin Permeability Factor, 1264
Beckett, Prof. J. C. : Queen's, a Short History of Queen's College, Belfast, and the Queen's University of Belfast, 1501
Beddoe, J. E. : Appointed to the Council of the Water Research Association, 1500
Bedford, A. W. : Awarded the R. P. Alston Medal of the Royal Aeronautical Society, 1648
Bedson, H. S., and Farmer, T. H. : Detection of Meprobamate on Paper Chromatograms, 43
Beecher, E. R. : Museum Treatment of Weakened Fabrics, 1501
Beekeeping (Old-time) : Exhibition of (Museum of English Rural Life, Reading), 1782
Beers, jun., Dr. Roland F. : Inhibition of Polynucleotide Phosphorylase by Degraded Ribonucleic Acid—its Reversal by various Agents, 1335
Beersheba : From Dan to—Excavations in North and South Palestine, *review* by Peter J. Parr, 951
Beet (Wild), *Beta patellaris* Moq., as Indicator : Testing Populations of Beet Eelworm, *Heterodera schachtii* Schmidt, for Resistance-breaking Biotypes, using the (Audrey M. Shepherd). 1141
Beet Eelworm, *Heterodera schachtii* Schmidt : Testing Populations of, for Resistance-breaking Biotypes, using the Wild Beet (*Beta patellaris* Moq.) as Indicator (Audrey M. Shepherd), 1141
Beetles : British Water (Prof. Frank Balfour-Browne), Vol. 3, *review* by Dorothy J. Jackson, 1420
  Proepithelial Regeneration in the Midgut of (A. Ameen and Dr. S. A. Shafiq), 913
Beevers, Dr. R. B. : Relaxation Processes, 583
Beginning of the 'Space Age' : The Universe at the (Dr. R. A. Lyttleton), 1019
Behaviour : Ciba Foundation Symposium on the Neurological Basis of (edited by G. E. W. Wolstenholme and Cecilia M. O'Connor), (in commemoration of Sir Charles Sherrington, 1857-1952), *review* by Dr. P: B. Bradley, 954
  Neurophysiology of, *review* by Dr. P. B. Bradley, 954
Behaviour of Dicobalt Octacarbonyl at Elevated Temperature and Carbon Monoxide Pressure (Sol Metlin, Irving Wender and Heinz W. Sternberg), 457
Behaviour in a Group of Small Animals : A Photographic Method for Recording Activity and (Dr. D. K. Edwards), 625
Behaviour of Invertebrates : An Introduction to the (Dr. J. D. Carthy), *review* by Dr. G. A. Horridge, 4
Behaviour of Sacculinized Shore Crabs (*Carcinus maenas* Pennent), (Erik Rasmussen), 479
Behaviour of Vacuum Arc Cathode Spots : An Effect of Oxide Layers on the (H. Wroe and R. H. Alderson), 1544
Behaviour (Chromatographic), of Human Albumin labelled with Iodine-131 (Dr. S. Cohen), 393
Behaviour (Etch), of Jacobsite with Different Cell Dimensions : Variation in (Dr. Supriya Roy), 1256
Behaviour (Injury-feigning), of Wood-Pigeons (C. S. Payne), 1643
Behaviour (Psychomotor), and Delinquency : Association between (H. S. Anthony), 343
Behaviour and Psychological Man (Prof. Edward Chace Tolman), *review* by Prof. John Cohen, 781
Being a Technologist : On (Prof. D. G. Christopherson), 1780
Beit Memorial Trust : Report for 1958-59, 1569
  Election of Sir Francis Glyn as a Trustee and honorary treasurer, 1569
  Appointment of Dr. Honor B. Fell to the Advisory Board, 1569
  Appointment of Sir Roy Cameron as secretary, 1569
  Elections to Fellowships, 1569
Bekku, Dr. S. : *Obituary*, 1017
Belford, Dr. D. S., and others : Copper–Cellulose Complexes, 988
Belkhode, M. L. (Nath, Prof. M. C., and) : Glucose-*cyclo*-Acetoacetate as a Precursor of Ascorbic Acid in Germinating Green Gram, 1258
Bell, Dr. D. A. : Physics for the Electrical Engineer, *review*, 707
Bell, E. J., and others : Parasitology (The *in vitro* Culture of Strigeid Metacercariae to the Sexually Mature Adult Fluke), 1506
Bell, Dr. F. R., and Williams, H. L. : Threshold Values for Taste in Monozygotic Twin Calves, 345
Bell, Dr. G. D. H. : Wheat Genetics, 26
  Obituary of Dr. Herbert Hunter, 1016
Bell, J. D., and others : 'Ring Angels' over South-East England, 1759
Bell, P. R. : Experimental Approaches to the Problems of Growth and Form in Plants (Experimental Investigation of the Pteridophyte Life-Cycle), 585
Bell Telephone Laboratories : Election of Dr. James B. Fisk as president, 220
  Election of Dr. M. J. Kelly as chairman of the board of directors, 220
  Appointment of Estill I. Green as executive vice-president, 220
  Appointment of Prof. J. W. Tukey as assistant director of research in communication principles, 648
  New laboratory at Holmdel, New Jersey, 1641
Bell Telephone Laboratories (Members of the Technical Staff of) : Transistor Technology, Vol. 1 (edited by H. E. Bridgers, J. H. Scaff and J. N. Shive), Vol. 2 (edited by F. J. Biondi), *review* by Dr. J. R. Tillman, 72
  Vol. 3 (edited by F. J. Biondi), *review* by Dr. J. R. Tillman, 1557
Bell Telephone Laboratories (Western Electric Company and the) : Synthetic Quartz Crystals, 294
Bell Telephone Laboratories and the American Institute of Electrical Engineers : Establishment of the Kelly Award, 510
Belson, W. A. : Matching and Prediction in the Social Sciences, 772
Bendall, J. R. : Reflexions on the Motility of Muscle, *review*, 278
Bendat, Dr. Julius S. : Principles and Applications of Random Noise Theory, *review* by R. A. King, 353
Bengtsson, Prof. Lars Ph. : Recovery of Injected Progesterone and its relation to the Onset of Human Labour, 405
Benjamin, P. (Weaver, C., and) : Interfacial Phenomena (Adhesion of Evaporated Metal Films to Glass), 1098
Benkö, A., and others : Changes produced in Serum Lipoproteins of Dogs by Cellulose containing Methyl Groups, 1119
Bennet, J. A. : Interfacial Phenomena (Electrical Resistivity of a Gold Film being deposited on Alumina or a Substrate of Bismuth Oxide on Alumina), 1097
Bennett, Dr. G. M. : *Obituary* by Dr. A. D. Mitchell, 717
Bennett, M. A. E., and others : Penicillin as an Antigen, 468
Bennett, M. C., and Cope, F. W. : Nuclear Fusion and Non-Fusion in *Theobroma cacao* L., 1540
Bennett, Dr. Winifred, and Garrison, Dr. Warren M. : Production of Amide Groups and Ammonia in the Radiolysis of Aqueous Solutions of Protein, 889
Bennewitz, Dr. H. G. : Chemistry and Quantum Chemistry, 159
Benney, W. E., and others : Changes in the Group *A* Antigen in a Case of Leukaemia, 892
Bennhold, H., and others : Albumin labelled with Iodine-131 in an Analbuminaemic Subject, 606
Bensch, Klaus G., and others : Phagocytosis and Cell Division, 476
  Variability of Content of Deoxyribonucleic Acid in *L*-strain Fibroblasts, 1818
Benson, A. (Lemberg, Prof. R., and) : Incorporation of Radioactive Iron into Haematin *a*, 678
Bentley, H. R., and Berry, E. G. N. (edited by) : The Constituents of Tobacco Smoke—an Annotated Bibliography, 1434
Bentley, O. G., and others (edited by) : Trace Elements—Proceedings of the Conference held at the Ohio Agricultural Experiment Station, 1957, *review* by Dr. E. J. Hewitt, 1009
Bentzon, M. W., and others : Synthesis of Deoxyribonucleic Acid during the Division Cycle of Bacteria, 1207
Benua, R. S., and others : Incorporation of 5-Iodouracil labelled with Iodine-131 into the Deoxyribonucleic Acid of Human Leukaemic Leucocytes following *in vivo* Administration of 5-Iododeoxyuridine labelled with Iodine-131, 1686
Benzene Hexachloride : Metabolism of, by Resistant Houseflies *Musca domestica* (Dr. F. R. Bradbury and H. Standen), 983
Benzenoid Compounds : Detection and Estimation of, by Chromatography (P. Moss and A. J. Thomas), 1611
5-Benzylidenerhodanine : Pharmacological and Toxicological Properties of (Salah A. Tawab, Prof. Ahmed Mustafa and A. F. A. Mawgoud Shalaby), 607
Bergel, Prof. F. : Elected a Fellow of the Royal Society, 860
Berger, Gaston : Elected a Fellow of the International Academy of Management, 1719
Berger, S., and others : Effect of Protein-free Diet on the Vitamin A Storage in the Rat Liver, 1597
Berggren, Lennart, and others : Bacterial and Testicular Hyaluronidase, 265
Bergmann, Prof. F. (Lachmann, Dr. J., and) : Dissociated Nystagmus in the Rabbit, 1065
Berkowitz, N. : The Nature of Coal (Decomposition and Diffusion Processes in Coal Pyrolysis), 1439
Berman, H., and Kibler, H. H. : Effect of Clipping the Coat on the Thermoregulatory Reactions of Dairy Heifers, 606
Bernal, Prof. J. D. : A Geometrical Approach to the Study of Liquids, 141
Berrie, Dr. Geoffrey K. : Mitosis in the Microspore of *Encephalartos barteri* Carruth., 834
Berry, E. G. N. (edited by Bentley, H. R., and) : The Constituents of Tobacco Smoke—an Annotated Bibliography, 1434
Berry, W. G., and others : Polynomial Representation of Steam Tables, 598
Berry and Dedrick : Reactivation of Heat-inactivated Poxviruses—a General Phenomenon which includes the Fibroma–Myxoma Virus Transformation of (Prof. Frank Fenner, I. H. Holmes, Dr. W. K. Joklik and Gwendolyn M. Woodroofe), 1340
Berson, F. A. : Antarctic Meteorology, 1504
Beryllium : Electrolytic Deposition of (Dr. I. A. Menzies, D. L. Hill and L. W. Owen), 816
Berz, I. : Effects of Arc Stage of Electrical Discharge on Ignition of Inflammable Gas, 669
Bessemer Gold Medal for 1959 of the Iron and Steel Institute awarded to Prof. Bo Kalling, 930
Besserer, C. W. : Missile Engineering Handbook, *review*, 210
Bestor, Prof. Arthur : Education in the Age of Science, 1436
Besznyák, I., and others : Effect of 1,6-Di-(2-Bromoethylamino)-1,6-Dideoxy-D-Mannitol Dihydrobromide on Tumours of Laboratory Animals, 395
β-Aminoethyl*iso*thiouronium Dibromide: Anti-Thyroid Action of, in Rats (John Osmer, Dr. Robert B. Jennings and Dr. Robert M. Dowben), 470
β-Aminoethylthiosulphuric Acid : Protective Effect of, against Ionizing Radiation (Bo Holmberg and Bo Sörbo), 832
β-Amino-*iso*butyric Acid : Urinary Excretion of, in Eskimo and Indian Populations of Alaska (Dr. A. C. Allison, Dr. B. S. Blumberg and Dr. S. M. Gartler), 118

β-Diketones : Metal–Oxygen Stretching Frequencies in the Metal Chelate Compounds of (Kazuo Nakamoto, Paul J. McCarthy and Arthur E. Martell), 459
β-Globulin Polymorphism and Early Foetal Mortality in Cattle (Dr. G. C. Ashton), 404
β-Glycine : Crystal Structure of (Dr. Yoichi Iitaka), 390
β-Hydroxybutyrate Injections : Effect of, on the Pancreatic Activity of Guinea Pigs (Dr. H. D. Brahmachari and Mahendra Kumar), 51
β-Oxidation of Aryloxy-alkylcarboxylic Acids by *Nocardia opaca* : Effect of Substitution in the Side-Chain on (D. M. Webley, R. B. Duff and V. C. Farmer), 748
β-Polymorphs of Uranium and Thorium Disilicides (A. Brown and J. J. Norreys), 673
β-Type Interlamellar Sorption Complexes (F. Aragón, J. Cano Ruiz and Dr. D. M. C. MacEwan), 740
β-, γ, and δ-Tocopherols (Pure α-,), in the Growing Chick : Relative Rates of Liver Storage of (T. W. Griffiths), 1061
Beta patellaris Moq. (Wild Beet), as Indicator : Testing Populations of Beet Eelworm, *Heterodera schachtii* Schmidt, for Resistance-breaking Biotypes, using the (Audrey M. Shepherd), 1141
Beth, Dr. Kurt (Thimann, Prof. Kenneth V., and) : Action of Auxins on *Acetabularia* and the Effect of Enucleation, 946
Bett, Dr. W. R. : Amphetamine Psychosis, *review*, 639
  The Haffkine Institute, Bombay—Diamond Jubilee, 725
  Obituary of Cyril Barnard, 1159
Betteridge, Dr. W. : Appointed superintendent of the Platinum Metals Research Laboratory of the Mond Nickel Development and Research Department, Acton, 1432 ; work of, 1432
Beutler, Dr. Ernest, and others : Incidence of the Erythrocytic Defect associated with Drug-Sensitivity among Oriental Subjects, 684
Beverage Technology and Distribution, 1936-56 : Bibliography of Food—a Select International Bibliography of Nutrition, Food and (E. Allan Baker and D. J. Foskett), *review* by Dr. Magnus Pyke, 351, 582
Beveridge, Gordon S. G., and Denbigh, Prof. Kenneth G. : High-Temperature Oxidation of Zinc Sulphide, 106
Beverley, Dr. J. K. A.: Congenital Transmission of Toxoplasmosis through Successive Generations of Mice, 1348
Beverton, R. J. H. : Appointed deputy director of fisheries research in the Ministry of Agriculture, Fisheries and Food, 1568 ; work of, 1568
Bhagavantam, Dr. S. : The Indian Institute of Science, Bangalore—Golden Jubilee, 644
Bharadwaj, Dr. T. P. (Love, Dr. Robert, and) : Two Types of Ribonucleoprotein in the Nucleolus of Mammalian Cells, 1453
Bhattacharya, Dr. Gangagobinda : Influence of Ions on the Uptake of Glucose and on the Effect of Insulin on it by Rat Diaphragm, 324
Bhattacharya, Dr. S. K. : Amperometric Determination of Sulphydryl Content of Blood and Tissues, 1327
BHC : Metabolism of, by Resistant Houseflies *Musca domestica* (Dr. F. R. Bradbury and H. Standen), 983
Bhide, Dr. N. K., and Aimen, R.A. : Pharmacology of a Tranquillizing Principle in *Paspalum scrobiculatum* Grain, 1735
Bhowmick, J. N. : The Nature of Coal (Aliphatic Hydrogen in Coal), 1439
Bibliographies on Geology, 932
Bibliography on the Chemistry of Tobacco Smoke, 1434
Bibliography on the Effects of Ionizing Radiations on Plants, 1896-1955 (Arnold H. Sparrow, John P. Binnington and Virginia Pond), *review* by Dr. Alma Howard, 639
Bibliography of Food—a Select International Bibliography of Nutrition, Food and Beverage Technology and Distribution, 1936-56 (E. Alan Baker and D. J. Foskett), *review* by Dr. Magnus Pyke, 351, 582
Bibliography of Natural History, Society for the : Election of Officers, 1094
Bibliography (Classified), of Gerontology and Geriatrics, Supplement 1. 1949-1955 (Dr. Nathan W. Shock), *review* by Prof. P. L. Krohn, 777
Bibliography (International), of Nutrition, Food and Beverage Technology and Distribution, 1936-56 : Bibliography of Food—a Select (E. Alan Baker and D. J. Foskett), *review* by Dr. Magnus Pyke, 351, 582
Bicentenary of the publication of the tenth edition of the 'Systema Naturae' by Linnaeus : Centenary of the formulation of the Theory of Evolution by Charles Darwin and Alfred Russel Wallace and the (Congress in Singapore to celebrate the), 723
Bicentenary of the Royal Botanic Gardens, Kew (Dr. W. B. Turrill), 1498
Bicentenary of the Royal Botanic Gardens, Kew : Vistas in Botany—a Volume in honour of the (edited by Dr. W. B. Turrill), *review* by Prof. W. H. Pearsall, 1484
Bickis, I. J. (Quastel, Prof. J. H., and) : Metabolism of Normal Tissues and Neoplasms *in vitro*, 281
Biddiscombe, E. F. (Scurfield, Dr. G., and) : Effects of Gibberellic Acid on Winter Pasture Production, 1196
Biggs, Dr. R. : Clinical Haematology in Medical Practice, *review*, 1151
Bignall, J. R. (edited by) : Carcinoma of the Lung, *review* by Dr. L. Foulds, 955
Bigsby Medal for 1959 of the Geological Society awarded to Prof. B. C. King, 364
Bijnaner Itihas (A History of Science), (Sri Samarendranath Sen), Vol. 2 (in Bengali), *review* by Dr. F. R. Allchin, 1353
Bile (Rabbit) : Ester Sulphate Pattern of (Dr. Harry Boström and Anders Vestermark), 1593
Biliary Obstruction (Acute) : Determination of Transaminase Activity in Dogs' Serum and Lymph after Hepatic Damage due to (Dr. P. Braun, Dr. M. Papp and Dr. I. Horváth), 48
Biligirirangan Hills, Mysore State, India : Trap-Shotten Rock from the (Prof. C. S. Pichamuthu), 483
Bilirubin Conjugation *in vitro* : Factors affecting the Rate of (Dr. E. Talafant and J. Továrek), 111
Bilirubin Metabolism in the Foetus (Dr. Rudi Schmid, Sur Buckingham, Gloria A. Mendilla and Lydia Hammaker), 1823
Bill, Mrs. M. C. (Roux, Dr. David G., and) : Mechanism of Formation of Anthocyanidins from Leucoanthocyani(di)ns, 42
Binaghi, R. (Halpern, Dr. B. N., and) : Selective Permeability of Living Tissues to Carbonic Acid, 1397
Binding of Water in Ferric Hydrate (Prof. O. Glemser), 1476
Binding of Water in some Hydroxides and Hydrous Oxides (Structure of some Hydroxides and Hydrous Oxides), (Prof. O. Glemser), 943
Binnington, John P., and others : Bibliography on the Effects of Ionizing Radiations on Plants, 1895-1955, *review* by Dr. Alma Howard, 639
Bioassay of Sheep Anterior Pituitary Glands (Dr. D. R. Lamond, H. M. Radford and A. L. Wallace), 1597
Bio-Astronautics : Armed Forces—National Research Council Committee on, to advice on the biological or medical aspects of space exploration, 651
Biochemical Analysis, *review* by Dr. I. D. P. Wootton, 779
  Methods of (edited by Prof. David Glick), Vol. 6, *review* by Dr. I. D. P. Wootton, 779
Biochemical Differentiation of Group *A* and 'Human *C*' *Streptococci* (R. W. Henningson), 182
Biochemical Engineering : Postgraduate Course in (University College, London), 933
Biochemical Heterogeneity of the Ribonucleic Acid synthesized by *Escherichia coli B* after Irradiation with Ultra-violet Light (Kenshi Suzuki and Jóji Ono), 395
Biochemical Society : Election of Sir Henry Dale to honorary membership, 18
  Symposium on Metals and Enzyme Activity, Leeds, 1956 (organized and edited by E. M. Crook), *review* by Dr. O. T. G. Jones, 968
Biochemical and Microbiological Technology and Engineering, Journal of, Vol. 1, No. 1, 1367
Biochemie : Radioaktive Isotope in der (Prof. Engelbert Broda), *review* by Dr. H. R. V. Arnstein, 1149
Biochemistry at the Royal College of Surgeons, 579
Biochemistry : Advances in Enzymology and related Subjects of (edited by F. F. Nord), Vol. 20, *review* by Dr. Edwin C. Webb, 961
  Annual Review of (edited by J. Murray Luck, in association with Frank W. Allen and Gordon Mackinney), Vol. 27, *review* by Prof. F. G. Young, 961
  Colorimetry in, *review* by Dr. N. R. Lawrie, 207
  Fourth International Congress of (Proceedings to be published by the Pergamon Press), 510
  General (Prof. Joseph S. Fruton and Prof. Sofia Simmonds), second edition, *review* by D. H. Northcote, 968
  New, *reviewed* by Prof. F. G. Young, 961
  Radioactive Isotopes in, *review* by Dr. H. R. V. Arnstein, 1149
  Textbook of (Prof. Benjamin Harrow and Prof. Abraham Mazur), seventh edition, *review* by Prof. F. G. Young, 967
Biochemistry, International Union of : Symposium on Haematin Enzymes, 1571
Biochemistry of Lombricine—Occurrence of D-Serine in Lombricine (Iva M. Beatty, Dr. D. I. Magrath and Prof. A. H. Ennor), 591 ; Synthesis of DL- and L-Lombricine (Iva M. Beatty and Dr. D. I. Magrath), 591
Biochemistry in Medicine, *review* by Prof. J. N. Davidson, 5
Biochemistry (Physical), at Canberra, 151
Biodynamics : Basic (E. J. Kempf), 933
Biographical Approach to John Dalton (Frank Greenaway), *review* by Prof. J. R. Partington, 1765
Biological Activity of L-Tryptophan Esters (Dr. Giulio C. Perri, Louis Kaplan and C. Chester Stock), 116
Biological Aspects of the Transmission of Disease—Report of the Institute of Biology Symposium (edited by C. Horton-Smith), *review* by Dr. C. W. Dixon, 1221
Biological Effects of Space Flight, 651
Biological Examination (Bacteriological, Chemical and), of the London Waters for the Years 1955-56 : Thirty-seventh Report on the Results of the (E. Windle Taylor), 798
Biological Fibres : Clay Minerals and (X-Ray Analysis Group of the Institute of Physics Conference on), 1024
Biological Fluids : Direct Determination of Drug Concentrations in, by Polarography (Dr. P. O. Kane), 1674
Biological Information—Theory and Practice, *review* by Dr. Roy Markham, 1292
Biological Origin of Manganese-rich Deposits of the Sea Floor (John W. Graham and Susan C. Cooper), 1050
Biological Properties of the S-(Methylcarbamyl) Methyl 0,0-Dimethyl-Dithiophosphate : Mode of Action and (R. Santi and P. de Pietri-Tonelli), 398
Biological Replication of Macromolecules (edited by F. K. Sanders), *review* by Dr. Roy Markham, 1292
Biological Research : A Century of (Illinois Natural History Survey, Bulletin, Vol. 27), 1233
Biological Sciences in the United States : Nuclear Training in the, 1091
Biological Term 'Pheromone' : The Proposed (H. S. Micklem), 1835 ; (Dr. P. Karlson and Prof. M. Lüscher), 1835
Biological Ultrastructure (Prof. Arne Engström and Dr. J. B. Finean), *review* by Dr. H. E. Huxley, 956
Biologically Active Substances : 'Pheromones', a New Term for a Class of (Dr. P. Karlson and Prof. M. Lüscher), 55
Biologische und Serologische Eigenschaften der Bartonellen : Morphologische, (Dr. Reinhard Wigand), *review* by Dr. A. Lwoff, 207
Biology : Electrical Techniques in Medicine and (American Institute of Electrical Engineers, the Institute of Radio Engineers and the Instrument Society of America twelfth Annual Conference on), 1434
  The Physical Foundation of (Prof. Walter M. Elsasser), *review* by Dr. W. Grey Walter, 955
  Polysaccharides in—Transactions of the Second Josiah Macy, Jr. Foundation Conference, Princeton, 1956 (edited by Dr. George F. Springer), *review* by Prof. M. Stacey, 1219
  Twelfth Brookhaven Symposium in (Structure and Function of Genetic Elements), 1094
Biology (Experimental), Society for : Symposia No. 12, The Biological Replication of Macromolecules (edited by F. K. Sanders), *review* by Dr. Roy Markham, 1292
Biology (Field) : A. Guide to (John Sankey), *review* by W. H. Dowdeswell, 1081
Biology (Marine), especially Fisheries : Shorewards Upslope of the Layer of Minimum Oxygen off Bombay—its influence on (Dr. J. N. Carruthers, S. S. Gogate, J. R. Naidu and T. Laevastu), 1084
Biology (Marine), or Oceanography : Grants for research in (Challenger Society), 1368
Biology (Molecular), Journal of, Vol. 1, No. 1, 1641
Biology (Quantitative) : Twenty-fourth Cold Spring Harbor Symposium on (Genetics and 20th Century Mendelism), 934
  Cold Spring Harbor Symposia on, Vol. 22, Population Studies—Animal Ecology and Demography, *review* by Dr. A. Milne, 1220

Biology of Hair Growth (edited by William Montagna and Richard A. Ellis), *review* by Dr. F. W. Dry, 851
Biology, Institute of : Symposium on the Biological Aspects of the Transmission of Disease (edited by C. Horton-Smith), *review* by Dr. C. W. Dixon, 1221
Biology, Institute of (Parasitology Group) : Spring Meeting at the University of Edinburgh (Discussion on Parasitology), 438, 1506
  Discussion on the Chemotherapy of Parasitic Diseases, 1029
Biology (Experimental) : International Symposium on, in commemoration of Lazzaro Spallanzani, 582
Biology (Human), Society for the Study of : Symposium on Natural Selection in Man, 159
Biology (*Radiation*), *International Journal of*, Vol. I, No. I, 1020
Biology Courses (College), on Television, 649
Biondi, F. J. (edited by) : Transistor Technology, Vol. 2, *review* by Dr. J. R. Tillman, 72 ; Vol. 3, *review* by Dr. J. R. Tillman, 1557
Biosynthesis of Cell Constituents from C_2-Compounds—Formation of Malate from Glycollate by *Pseudomonas ovalis* Chester (Dr. H. L. Kornberg and A. M. Gotto), 1791 ; Metabolism of Glycine by a Pseudomonad (A. G. Callely and Dr. S. Dagley), 1793 ; Formation of Glycerate from Oxalate by *Pseudomonas oxalaticus* (OXI) grown in Oxalate (J. R. Quayle and Dr. D. B. Keech), 1794
Biosynthesis in Chick Liver : Vitamin B_{12} and (Vitamin B_{12} and Protein Biosynthesis), (Dr. M. J. Fraser and Dr. E. S. Holdsworth), 519
Biosynthesis of Ovalbumin (Prof. D. V. Siva Sankar and Henry W. Theis), 1057
Biosynthesis in Rat Liver : Vitamin B_{12} and (Vitamin B_{12} and Protein Biosynthesis), (Dr. H. R. V. Arnstein and Dr. J. L. Simkin), 523
Biosynthesis of Rubber (Dr. J. A. Gascoigne and Patricia Jones), 819
Biosynthesis and Constitution of Lignin (Prof. Karl Freudenberg), 1152
Biosynthesis (Protein) : Vitamin B_{12} and—Vitamin B_{12} and Biosynthesis in Chick Liver (Dr. M. J. Fraser and Dr. E. S. Holdsworth), 519 ; Vitamin B_{12} and Biosynthesis in Rat Liver (Dr. H. R. V. Arnstein and Dr. J. L. Simkin), 523
Biosynthesis (Purine) : Feedback Control of, by Purine Ribonucleotides (Dr. James B. Wyngaarden and Doris M. Ashton), 747
Biosynthesis (Trehalose), in the Locust : Site and Mode of (D. J. Candy and Dr. B. A. Kilby), 1594
Biotypes (Resistance-breaking) : Testing Populations of Beet Eelworm, *Heterodera schachtii* Schmidt, for, using the Wild Beet (*Beta patellaris* Moq.) as Indicator (Audrey M. Shepherd), 1141
Birch, H. F. : Simultaneous Decomposition Processes in Soils, 1415
Bird, Junius, and others : Radiocarbon Measurements on Samples of Known Age, 1582
Bird (Oliver) Prize for 1958 awarded to Prof. M. C. Shelesnyak, 1643
Bird Migration, Vol. 1, No. 1 (British Trust for Ornithology), 436
Birds : The Folklore of (Edward A. Armstrong), *review* by M. C. Burkitt, 1422
  Fossil (Dr. W. E. Swinton), *review*, 73
  The Work Output of Animals—Flight by, and by Man-power (Dr. D. R. Wilkie), 1515
Birds of Cyprus (Dr. David A. Bannerman and W. Mary Bannerman), *review* by Sir Landsborough Thomson, 967
Birds of Poland (Ptaki Ziem Polskich), (Jan Sokolowski), Tom 2, *review* by B. Nowosielski-Slepowron, 73
Birds of Stowe : An Account of the (Stowe School), 1718
Birds (Egyptian) : Systematic and Experimental Studies on Protozoal Blood Parasites of (Dr. A. H. Helmy Mohammed), *review* by Dr. Elizabeth U. Canning, 1081
Birds (Marine) : Salt Excretion in (Dr. L. Harrison Matthews), 202
Birds and Mammals of Canada, 154
Bireska, Mme. : Phosphates and Organic Substances in Nitrogen Deficiency, 513
Birkbeck College, London : Title of reader in crystallography in the University of London conferred on Dr. C. H. Carlisle, 794
Birmingham College of Technology : Conference on Electronic Digital Computers and their Industrial Applications, 154
Birth of Nigeria's University (Dr. Kenneth Mellanby), *review* by Sir Eric Ashby, 137
Birth of the Steamboat (H. Philip Spratt), *review* by A. W. Jones, 1626
Bishop, Dr. Ann : Elected a Fellow of the Royal Society, 860
  Chemotherapy of Parasitic Diseases (Resistance to Drugs in Parasitic Protozoa), 1029
Bishop, Dr. Alan W., and Henkel, D. J. : The Measurement of Soil Properties in the Triaxial Test, *review* by Thomas Whitaker, 1151
Bishop, J. S., and others : Mechanism of Action of Insulin, 1123
Bishop, Dr. M. W. H. (Lovelock, Dr. J. E., and) : Prevention of Freezing Damage to Living Cells by Dimethyl Sulphoxide, 1394
Bishop, Dr. P. M. F., and others : A Presumptive Human *XXY*/*XX* Mosaic, 1030
Bishop, Prof. R. E. D. : Development in Photoelasticity—Commemoration at University College, London, 1495
Biswas, B. B., and Sen, S. P. : Relationship between Auxins and Nucleic Acid Synthesis in Coleoptile Tissues, 1824
Bivalent Metal Ions : Reversal of Antibiotic Action of Cycloheximide (Actidione) by (M. Blumauerová and J. Stárka), 261
Bjerknes, Prof. J. : Awarded the International Meteorological Organization Prize of the World Meteorological Organization, 1567 ; work of, 1567
Bjerrum, Prof. J., and co-workers : Co-ordination Chemistry (Kinetics of the Hydrolysis of Chromic Complexes), 1784
Bjerrum, Prof. Niels : *Obituary* by Prof. J. R. Partington, 290
Björnerstedt, Rolf, and others : Bone and Radiostrontium, *review* by J. Vennart, 965
Black, G., and others : Polynomial Representation of Steam Tables, 598
Black, Maurice : Awarded a research grant by the Leverhulme Trust, 1499
Black Beans (*Phaseolus vulgaris*) : Purification of a Toxic Phytohaemagglutinin from (Dr. Werner G. Jaffé and Karl Gaede), 1329
Black Fens : The (A. K. Astbury), *review* by Dr. M. A. Morgan, 965
Black Sea : Microbiology and Water Circulation in the (A. E. Kriss), 437
Blackall, Dr. William E., and Grieve, Dr. Brian J. : How to Know Western Australian Wildflowers, Part 2, A Key to the Flora of the Temperate Regions of Western Australia, *review* by V. S. Summerhayes, 1628
Blackband, W. T.: Space Research (System for the Recovery of Information from vehicles as far away as the nearer Planets), 363
Blackband, W. T., and others : Deduction of Ionospheric Electron Content from the Faraday Fading of Signals from Artificial Earth Satellites, 1172
Blackbirds : A Study of (Dr. D. W. Snow), *review* by Dr. R. A. Hinde, 1767
Blackcliff and Wyndcliff Forest Nature Reserve (Nature Conservancy), 1650
Blackcoated Worker : The (David Lockwood), *review*, 494
Blackburn, T. H., and others : Assimilation of Ammonia Nitrogen by Rumen Bacteria, 402
Blackett, Prof. P. M. S. : *Obituary* of Prof. Arturo Duperier, 1015
  The British Association Looks Ahead, 1569
Blackie, Dr. M. S., and Gold, Dr. V. : Magnetometric Titration—a New Method of Chemical Analysis, 1804
Blackman, Prof. G. E. : Elected a Fellow of the Royal Society, 860
Blackman, Dr. L. C. F., and others : Metallic Conduction in the Crystal Compounds of Graphite, 454
Blackman, M. : Interfacial Phenomena (Epitaxial Polymorphism of Thallium and Caesium Halides), 1097
Blackwell, B. D. : Awarded the Branch Prize of the Royal Aeronautical Society, 1649
Bladder-Wall in the Rabbit : Absorption of Radioiodine through the (Oskar Andrysek and Ota Schück), 893
Blain, Dr. Isabel : Comments on the Job, 372
Blair, Alberta (Segal, Dr. Stanton, and) : Effect of Salicylate on Muscle Phosphorylase, 1609
Blair, D. T. A., and others : Gas Discharges (Spark, High-frequency and Glow Discharges), 93
Blair, Dr. G. W. Scott : An Equation for the Flow of Blood, Plasma and Serum through Glass Capillaries, 613
Blake, G. M. : Control of Diapause by an 'Internal Clock' in *Anthrenus verbasci* (L.) (Col., Dermestidae), 126
Blakely, J. M., and Mykura, H. : Interfacial Phenomena (Surface Tension of Metallic Interfaces), 1098
Bland, J. A., and Basinski, S. J. : Crystal Symmetry of Struvite (Guanite), 1385
Blanshard, Prof. Brand : Education in the Age of Science, 1437
Blaxter, J. H. S., and others : 'Chloride-Secretory' Cells in the Gills of Teleosts, 1248
Bleakney, Prof. Walker : Elected a member of the United States National Academy of Sciences, 1575
Bleichert, A. (Reichel, Prof. H., and) : Excitation–Contraction Coupling in Heart Muscle, 826
Blindness (Colour-) in Klienfelter's Syndrome (Prof. Curt Stern), 1452
Bloat in Cattle (Dr. M. J. Head), 757
Block, Dr. Richard J. (Werner, Dr. Sidney C., and) : Discrepancy between the Distributions of Iodine in Human Serum when estimated by Iodine-131 and Iodine-127, 406, *erratum*, 722
Block (Ganglionic), and Monoamine Oxidase Inhibitors (Dr. Sheldon B. Gertner), 750
Block and Graft Co-polymers : Stereo-specific Polymers and (Bradford Institute of Technology Course on), 224
Blocking Agents (Neuromuscular), of Short Duration (C. G. Haining, R. G. Johnston and J. M. Smith), 542
Blom, Dr. Erik : A Rare Sperm Abnormality—'Corkscrew-sperms' associated with Sterility in Bulls, 1280
Blood : Carbon Monoxide Content of the, and other Observations on Weddell Seals (Dr. L. G. C. E. Pugh), 74
  5-Hydroxytryptamine in, during Experimental Traumatic Shock in Rats (M. Medaković and I. Spuzić), 1685
  Research on Diseases of the (Lady Tata Memorial Trust Grants, Scholarships and Fellowships for), 581
Blood of Two Full-term New-born Babies with Multiple Malformations : Co-existence of the Embryonic (Third Normal) Haemoglobin Fraction with Erythroblastosis in the (Prof. I. Halbrecht, Ch. Klibanski, and F. Bar Ilan), 327
Blood (Duck), incubated *in vitro* with $NaH^{14}CO_3$: Labelled Keto-Acids in (A. Breccia, A. L. Fantola, G. Giustina and E. Lazzarini), 1328
Blood (Mammalian) : Anticoagulant Action of Fibrin Surfaces on (Dr. A. L. Copley, D. Steichele, M. Spradau and R. S. Thorley), 1683
Blood (Spermatic Vein) : Androgens in the Bovine Testis and (H. R. Lindner), 1605
Blood and Liver Xanthine Dehydrogenase of Rats : Effect of Salicylate on (Emilio Mitidieri and Ottilia R. Affonso), 471
Blood, Plasma and Serum through Glass Capillaries : An Equation for the Flow of (Dr. G. W. Scott Blair), 613
Blood and Serum of Non-immunized and Immunized Animals : Factors Inhibiting and Stimulating Growth of *Mycobacteria* in the (J. Hubáček and I. Málek), 187
Blood and Tissues : Amperometric Determination of Sulphydryl Content of (Dr. S. K. Bhattacharya), 1327
Blood-clotting Activity of the Venom of *Bothrops jararaca* (Dr. Olga B. Henriques, Dr. Fajga R. Mandelbaum and Dr. S. B. Henriques), 114
Blood Cells (Red) : Rate of Exchange of Phosphate in—Effect of Thyroid Hormones (A. M. Ermans and Prof. P. A. Bastenie), 679
Blood-Group Investigation on Central Kalahari Bushmen (Dr. J. S. Weiner and Dr. A. Zoutendyk), 843
Blood Group Phenotype K–, k–, Kp(a–b–) : A Further Example of the Kell (Hiroko Kaita, Marion Lewis, Dr. Bruce Chown and Eileen Gard), 1586
Blood Groups in Man (Dr. R. R. Race and Dr. Ruth Sanger), third edition, *review* by Dr. F. Stratton, 280
Blood Parasites (Protozoal), of Egyptian Birds: Systematic and Experimental Studies on (Dr. A. H. Helmy Mohammed), *review* by Dr. Elizabeth U. Canning, 1081
Blood Platelets (Human) : Taurine in (Julian Frendo, Aleksander Koj and Jan M. Zgliczyński), 685
Blood Sample (Human), belonging to Group AB : A Rare Variant of B in a (Dr. J. Moullec and Dr. P. Le Chevrel), 1733
Blood Smears : Feulgen–Naphthoic Acid Hydrazide Reaction applied to (Dr. R. K. Archer), 820
Blood Supply of Bone : Iodine-131 Clearance-rates as an Indication of the (Dr. P. G. Laing and Dr. Albert B. Ferguson, jun.), 1595
'Blood Thromboplastin' : Arginine Esterase Activity of (Phyllis M. Arscott, J. L. Koppel and John H. Olwin), 753
Blow-hole Theory : Simulation of Lunar Craters—a (Dr. A. G. Gaydon and R. C. M. Learner), 37

Blue Tetrazolium : Photochemical Reduction of, by Isolated Chloroplasts (John J. Taylor and Prof. Meyer Chessin), 626
Blue–Snow Goose Complex : Assortative Mating and Reciprocal Difference in the (Dr. F. G. Cooch and Dr. J. A. Beardmore), 1833
Blumauerová, M., and Stárka, J. : Reversal of Antibiotic Action of Cycloheximide (Actidione) by Bivalent Metal Ions, 261
Blumberg, Dr. B. S., and others : Urinary Excretion of β-Amino-*iso*butyric Acid in Eskimo and Indian Populations of Alaska, 118
Blyth, Dr. F. G. H. : Appointed reader in engineering geology at the Imperial College of Science and Technology, 1571
Boag, Dr. J. W., and Müller, A. : Changes in the Electron Spin Resonance Spectrum of Glycine with Increasing Doses of Radiation, 831
  Electron Spin Resonance in Irradiated Deoxyribonucleic Acid, 831
Boag, Dr. J. W. (Dewey, D. L., and) : Modification of the Oxygen Effect when Bacteria are given Large Pulses of Radiation, 1450
Boas, Prof. Marie : Robert Boyle and Seventeenth-Century Chemistry, *review* by Dr. R. E. W. Maddison, 850
Bodanszky, Dr. Miklos, and du Vigneaud, Prof. Vincent : Synthesis of Oxytocin by the Nitrophenyl Ester Method, 1324
Boddington, Lewis : Appointed to the rank of chief scientific officer, and director-general of Aircraft Research and Development (R.A.F.), 1231 ; work of, 1231
Boden, Brian P., and others : Electrical Response to Illumination of the Euphausiid Crustacean Eye, 1820
Bodenheimer, Prof. F. S. : Animal Ecology To-day, *review* by Dr. A. Milne, 1220
Body, R. A. F., and others : Reaction of some Silicates with Chelating Agents, 99, *erratum*, 1719
Body (Weight of), in Rats : Effect of Reduction of Stimulation on Consumption of Food, Intake of Water and (Dr. Karl Weiss and Harry M. B. Hurwitz), 344
Body Fluids : Rapid Specific Method for Determination of Aldosaccharides in (Dr. Eric Hultman), 108
Body-centred Cubic Chromium–Iron and Chromium–Manganese Alloys : Low-temperature Specific Heats of (C. T. Wei, C. H. Cheng and Prof. P. A. Beck), 315
Boelsma, E., and others : Composition of Lipids isolated from the Aorta, Coronary Arteries and Circulus Willisii of Atherosclerotic Individuals, 47
Bogoch, Elenore S. (Bogoch, Dr. Samuel, and) : Effect of Brain Ganglioside on the Heart of the Clam, 53
Bogoch, Dr. Samuel, and Bogoch, Elenore S. : Effect of Brain Ganglioside on the Heart of the Clam, 53
Bogorov, V. G., and Kreps, E. M. : Water Circulation in Oceans, 437
Bohm, D. : Problems of Collective Motion in Physics (Plasma Problems in the Electron Theory of Metals), 866
Bohr, Dr. Niels : Atomic Physics and Human Knowledge, *review* by Prof. W. H. McCrea, 1218
Bohr Effect : Molecular Adaptation in Haemoglobins—Nature of the (Austen Riggs), 1037
Bok, Prof. Bart J. : The Astronomer's Universe, *review* by Sir H. Spencer Jones, 1221
Bolognari, A. : Ultrastructure of Nucleoli in Oocytes of *Patella coerulea*, 1136
Bolton, Dr. J. G. : Appointed the first director of the newly-established Radio Observatory of the California Institute of Technology, 506 ; work of, 506
Boltz, C. L. : Appointed Science Correspondent in the News Division of the British Broadcasting Corporation, 1231 ; work of, 1231
Bombay : Shorewards Upslope of the Layer of Minimum Oxygen off—its Influences on Marine Biology, especially Fisheries (Dr. J. N. Carruthers, S. S. Gogate, J. R. Naidu and T. Laevastu), 1084
Bombardment (Electron) : Effects of, upon Bromides of Cadmium and Silver (Sho Suzuki), 1755
Bombing (Nuclear), and the Life of Man : The Devil's Repertoire or (Victor Gollancz), *review* by R. Brightman, 952
Bond Energies of some Alkali Fluorides (Dr. F. M. Page and Dr. T. M. Sugden), 1672
Bondi, Prof. H. : Elected a Fellow of the Royal Society, 860
Bonding (Intracellular Hydrogen), in Heterocyclic Systems (E. W. Gill and E. D. Morgan), 248
Bone : Iodine-131 Clearance-rates as an Indication of the Blood Supply of (Dr. P. G. Laing and Dr. Albert B. Ferguson, jun.), 1595
Bone and Radiostrontium (Arne Engström, Rolf Björnerstedt, Carl-Johan Clemedson and Arne Nelson), *review* by J. Vennart, 965
Bone (Animal) : Estimation of Strontium in, using X-Ray Fluorescence Analysis (W. M. B. Roberts), 887
Bone-Marrow in Irradiated Mice : Effect of Pyrimidine Deoxyribonucleotides on the Regeneration of (Dr. Z. Karpfel, J. Soška and V. Drášil), 1600
Bones (Animal) : Radioactivity of Soils, Plant Ashes and (Sir Ernest Marsden), 924
Bonner, Prof. David : Elected a member of the United States National Academy of Sciences, 1575
Bonner, Prof. Tom : Elected a member of the United States National Academy of Sciences, 1575
Bonsall, F. F.: Appointed to the chair of pure mathematics at King's College, Newcastle-upon-Tyne, 1365 ; work of, 1365
Book (The True), about Insects (John Clegg), *review* by B. D. Moreton, 709
Booker, D. V. : Caesium-137 in Dried Milk, 921
Books : Polish Scientific (Exhibitions at Oxford, Cambridge and Glasgow), 582
Books : Recent Scientific and Technical, Supp. v, January 31 ; Supp. vi, February 28 ; Supp. vi, March 28 ; Supp. vi, April 25 ; Supp. vi, May 30 ; dcclxx, June 27
Books required for the 'Oxford English Dictionary', 1434
Books (British), and Information Services Overseas, 1417
Booth, Dr. A. : Experimental Approaches to the Problems of Growth and Form in Plants (Factors affecting the Production of Stolons in the Potato), 585
Booth, Dr. A., and others : Use of Radioactive Tracers in Studies of the Shoot Apex, 1580
Booth, Dr. D. L., and others : Nuclear Fuel Cycles (Perturbations due to Fuel Cycles), 1647
Boothroyd, Dr. A. R. : Appointed to the University of London readership in electronics at the Imperial College of Science and Technology, 794
Borasio, Dr. L. : Phosphates and Organic Substances in Nitrogen Deficiency, 513
Bordetella pertussis : Reduced Activity of Histaminase in Rats sensitized by (Makoto Niwa, Yutaka Yamadeya, Toshitaka Matsui and Prof. Yoshio Kuwajima), 755 ; (Toshitaka Matsui, Masayoshi Kishigami and Prof. Yoshio Kuwajima), 756
Boreal Age : A Marine Transgression of, in the Southernmost Part of Norway (Gunnar Gabrielsen), 1616
Borehole to the Earth's Mantle : Drilling a (Prof. Hans Pettersson), 436
Borides and Silicides of the Platinum Metals (B. Aronsson, J. Åselius and E. Stenberg), 1318
Borlaug, Dr. N. E. : Wheat Genetics, 25
Born, Dr. G. V. R., and Esnouf, Dr. M. P. : Appearance of a Phosphorus Compound in Platelet-rich Plasma on Clotting, 478
Borohydride (Sodium) : Reaction of, with Wool (J. M. Gillespie), 322
Boron : Effect of, on the Rooting of Clematis Cuttings (Dr. C. J. Weiser), 559
  Isotopic Composition of, and its Atomic Weight (W. J. Lehmann and I. Shapiro), 1324
Boron Supply : Effect of, on the Sugars, Soluble in 80 per cent Ethanol, in Flax Seedlings (T. F. Neales), 483
Borradaile's Manual of Elementary Zoology, thirteenth edition, revised by W. B. Yapp, *review* by Dr. V. Fretter, 1290
Borwein, Dr. D. : Elected a Fellow of the Royal Society of Edinburgh, 719
Bosanquet, C. H. : Peak Dimensions in Gas Chromatography, 252
Bose, Dr. M. N., and Dev. Sukh: Occurrence of Two Characteristic Wealden Ferns in the Jabalpur Series, 130
Bose, N. K. : Appointed director of the Department of Anthropology, Government of India, 719 ; work of, 719
Bose—Einstein Statistics and Helium Films (A. D. Singh and R. K. Pathria), 668
Boss, Prof. Willis R. : Appointed Science Officer in the American Embassy in Tokyo, 15
Boström, Dr. Harry, and Vestermark, Anders : Ester Sulphate Pattern of Rabbit Bile, 1593
Botanic Gardens (Royal), Kew : Bicentenary of the (Dr. W. B. Turrill), 1488
  Vistas in Botany—a Volume in honour of the Bicentenary of the (edited by Dr. W. B. Turrill), *review* by Prof. W. H. Pearsall, 1484
Botanical Congress : Ninth International (Canadian Department of Agriculture), 1502
Botanical Studies : Present Trends in, *review* by Prof. W. H. Pearsall, 1484
Botany at Aberdeen, 1640
Botany : Vistas in—a Volume in honour of the Bicentenary of the Royal Botanic Gardens, Kew (edited by Dr. W. B. Turrill), *review* by Prof. W. H. Pearsall, 1484
Bothrops jararaca : Blood-clotting Activity of the Venom of (Dr. Olga B. Henriques, Dr. Fajga R. Mandelbaum and Dr. S. B. Henriques), 114
Bott, Dr. M. H. P. : Awarded the Wollaston Fund for 1959 of the Geological Society, 364
  Automatic Reduction of Geophysical Data (Use of a Digital Computer for determining the extent of Geological Formations from Surface Gravity Anomalies), 1167
Böttcher, Prof. C. J. F. : Relaxation Processes (Phenomenological Study of Dielectric Relaxation), 583
Böttcher, Prof. C. J. F., and others : Composition of Lipids isolated from the Aorta, Coronary Arteries and Circulus Willisii of Atherosclerotic Individuals, 47
Bottini, Dr. E. : Phosphates and Organic Substances in Nitrogen-Deficiency, 513
Bottom Fauna (British Marine) : New Members of the (G. M. Spooner), 1695
Botvinik, Prof. M. M. : Synthesis of Peptides (Synthesis of Optically Active Peptides from Racemic Amino-esters), 152
Boulind, Dr. H. F. : Science and Education, 300
Boundary Lubricant : Material Transfer in Monomolecular Layers of a (George L. Gaines, jun.), 1110
Boundary Problems in Differential Equations (Mathematics Research Center, United States Army, Symposium on, at the University of Wisconsin), 224
Bourne, Prof. Geoffrey H., and Golarz, M. Nelly: Human Muscular Dystrophy as an Aberration of the Connective Tissue, 1741
Bovey, Dr. Frank A. : The Effects of Ionizing Radiation on Natural and Synthetic High Polymers, *review* by Prof. C. E. H. Bawn, 637
Bovine Testis and Spermatic Vein Blood : Androgens in the (H. R. Lindner), 1605
Bowen, Dr. D. H. : Hydrogen Liquefaction, 1504
Bowen, H. J. M., and Smith, S. R. : Effect of γ-Radiation on Weeds, 907
Bowen, J. H., and Masters, E. F. O. : Nuclear Reactor Control and Instrumentation, *review* by R. Vaux, 1149
Bowie (William) Medal awarded to Prof. W. M. Elsasser, 1502
Bowman, J. C., and Archibald, J. D. H. : Effect on Controlled Lighting on Production Characters in the Fowl, 1138
Bownas, Geoffrey : Awarded a research grant by the Leverhulme Trust, 1499
Bowyer, E. C. : Honorary Companionship of the Royal Aeronautical Society conferred on, 1648
Boycott, B. B., and Guillery, Dr. R. W. : Environmental Temperature and the Reptilian Nervous System, 62
Boyd, Dr. R. L. F. : Gas Discharges (Probe Measurements in Striated Positive Columns), 93
  Space Research, 361
  Title of reader in physics in the University of London (at University College) conferred on, 368
Boyle, Robert, and Seventeenth-Century Chemistry (Prof. Marie Boas), *review* by Dr. R. E. W. Maddison, 850
Brabazon of Tara, Lord : Elected president of the Royal Institution, 1571
Brachiosaurus Exhibition at the Smithsonian Institution, 649
Brackman, W. : Co-ordination Chemistry (Copper–Amine Complexes which Catalyse the Oxidation of Alcohols), 1785
Bradbury, A., and others : Removal of Dipolar Broadening of Nuclear Magnetic Resonance Spectra of Solids by Specimen Rotation, 1802
Bradbury, E. M., and others : α-Helices and a New Polypeptide Fold in Poly-β-Benzyl-L-Aspartate, 1736
Bradbury, Dr. F. R., and Standen, H. : Metabolism of Benzene Hexachloride by Resistant Houseflies, *Musca domestica*, 983

Bradbury, Dr. J. H. : Separation and Analysis of Scale-rich Material from Wool, 305
Bradbury, S. : Methods of Analytical Histology and Histo-Chemistry, *review*, 211
Bradford Chemical Society, and others : Symposium on Radiation Chemistry, 18
Bradford Institute of Technology : Course in Stereospecific Polymers and Block and Graft Co-polymers, 224
Bradford Institute of Technology (Department of Chemical Technology), and others : Symposium on Radiation Chemistry, 18
Bradley, D. E. : Electron-Microscopic Study of Finback Whale Myoglobin Crystals, 941
Bradley, Dr. P. B. : The Excitable Cortex in Conscious Man, *review*, 781
  Neurophysiology of Behaviour, *review*, 954
Bradley, Dr. W. F. : Density of Water Sorbed on Montmorillonite, 1614
Bradshaw, A. D., and Snaydon, R. W. : Population Differentiation within Plant Species in Response to Soil Factors, 129, *erratum*, 368
Braekkan, Olaf R. : Red Muscle as a Possible Character for the Identification of Sharks, 556
Braham, Roscoe R. (Byers, Horace R., and) : Grant of 114,300 dollars from the National Science Foundation, for a study of the physical effects of silver iodide seeding over the Great Plains, 1371
Brahmachari, Dr. H. D., and Kumar, Mahendra : Effect of β-Hydroxybutyrate Injections on the Pancreatic Activity of Guinea Pigs, 51
Braille Translation by Computer, 1233
Brain, C. K. : The Transvaal Ape-Man-bearing Cave Deposits, 1433
Brain, Sir Russell : Science, Philosophy and Religion (Eddington Memorial Lecture for 1959), 154, 1022
Brain : Thudichum—Chemist of the (Prof. David L. Drabkin), *review* by H. W. Kosterlitz, 568
  The Computer and the (Dr. John von Neumann), *review* by A. H. Armstrong, 350
Brain (Rat) : Effect of Toxopyrimidine on Glutamic-decarboxylase and Glutamic-oxalacetic Transaminase of (Dr. G. Rindi, V. Perri and U. Ventura), 1126
Brain of the Living Rat : Formation of Urea from Arginine in the (Michael B. Sporn, Wesley Dingman, Alfred Defalco and Robert K. Davies), 1520
Brain-case of the Common Shrew (*Sorex araneus* L.) : Seasonal Changes in the (Peter Crowcroft and Jean M. Ingles), 907
Brain Damage : Oxygen Exposure and (Lars Gyllenstein), 1068
Brain Extracts : Fractionation of, for Acid Phosphatase-elevating Activity (Dr. V. Schreiber, Prof. J. Charvát, V. Kmentová and M. Rybák), 473
Brain Ganglioside : Effect of, on the Heart of the Clam (Dr. Samuel Bogoch and Elenore S. Bogoch), 53
Brain Stem (Rat): Selective Staining of Visceral Efferents in the, by a Modified Koelle Technique (Dr. P. R. Lewis and Dr. C. C. D. Shute), 1743
Brain Tissue of Rats : Succinic Dehydrogenase Activity in, after Ovariectomy and Steroid Administration (H. Sobel and B. Eckstein), 54
Brains of Rats treated with Toxopyrimidine : γ-Aminobutyric Acid and Glutamic Acid Content of (Dr. G. Rindi and G. Ferrari), 608
Braithwaite, E. R. : Measurement of the Flocculation of Suspensions, 740
Bramhall, James L. (Ruebner, Dr. Boris, and) : Effect of Dietary Protein on the Severity of Experimental Mouse Hepatitis, 609
Branch Prize of the Royal Aeronautical Society awarded to B. D. Blackwell, 1649
Branded Textiles Group (Textile Institute, in collaboration with the) : Conference on Detergents, Textiles and Dyes, 1236
Brandhorst, Dr. Wilhelm : Relationship between the Hake Fishery and a Southerly Sub-surface Return Flow below the Peru Current off the Chilean Coast, 1832
Brandly, C. A., and Jungherr, E. L. (edited by) : Advances in Veterinary Science, Vol. 4, *review* by Prof. H. Burrow, 1555
Brassica oleracea var. (Chou Moellier) : A Germination Inhibitor and Root-Growth Retarder in (A. G. Campbell), 1263
Brassington, Nancy (Haber, Alan H., and) : Non-respiratory Gas released from Seeds during Moistening, 619
Brattain, Dr. Walter : Elected a member of the United States National Academy of Sciences, 1575
Brattström, Prof. Hans : Pogonophora in the Hardnagerfjord, Western Norway, 1458
Braun, Dr. P., and others : Determination of Transaminase Activity in Dogs' Serum and Lymph after Hepatic Damage due to Acute Biliary Obstruction, 48
  Changes in Serum Transaminase Activity following Myocardial Damage due to Lymphatic Congestion, 1333
Braun-Falco, Dr. O., and Salfeld, Dr. K. : Leucine Aminopeptidase Activity in Mast Cells, 51
Bray, R. J. (Loughhead, R. E., and) : 'Turbulence' and the Photospheric Granulation, 240
Bray, W. J. : Awarded a Premium by the Radio Industry Council, 1023
Braye, E. H. (Hübel, W., and) : Co-ordination Chemistry (New Compounds from Iron Dodecacarbonyl and Acetylenes), 1785
Bread (Whole), and Bread Crumb : Moisture Content of (Y. Pomeranz), 1122
Bread Crumb : Moisture Content of Whole Bread and (Y. Pomeranz), 1122
Breakdown : Light Emission from Insulating Liquids due to Excitation by d.c. Fields near (M. Darveniza), 743
Breakdown of Homogeneous Field and Sphere Gaps : Effect of Radiation on the (K. R. Allen and Dr. K. Phillips), 233
Breakdown of a 1-cm. Homogeneous Field Spark Gap in Air : Effect of Humidity on the (Dr. K. Phillips, K. R. Allen and A. Refsum), 532
Breakdown Voltage (Spark) : Effect of Humidity on the (K. R. Allen and Dr. K. Phillips), 174
Breast Cancer (Human) : Variables related to (A. Elving Anderson, Harold O. Goodman and Sheldon C. Reed), *review* by Dr. L. Foulds, 955
Breast Muscles (Poultry), at Slaughter : Changes in *p*H and Temperature in (F. E. Peters and J. W. Dodge), 687
Breast Tumours in Mice of the *IF* Strain : Local Inhibition by Lactation of chemically induced (June Marchant), 629
Breccia, A., and others : Labelled Keto-Acids in Duck Blood incubated *in vitro* with $NaH^{14}CO_3$, 1328
Breeding of *Anopheles gambiae* : Relationship between Salinity and, in North-Eastern Tanganyika (A. Smith and J. W. Vail), 1203
Breeding of Small Animals : Measuring Productivity in (Dr. W. Lane-Petter, Annie M. Brown, Margaret J. Cook, G. Porter and A. A. Tuffery), 339
Breeding 10,000,000 Cattle (Milk Marketing Board), 1641
Bremner, Dr. J. M., and others : Release of Fixed Ammonium from Soil by Ball Milling, 1414
Brennan, Dr. D., and Fletcher, P. C. : Heterogeneous Atomization of Hydrogen and Oxygen, 249
Brenner, Prof. M. : Synthesis of Peptides (Peptides of the Hydroxy-amino-Acids), 152
Brewbaker, Dr. J. L., and Shapiro, N. : Homozygosity and *S* Gene Mutation, 1209
Brewer, Prof. Leo : Elected a member of the United States National Academy of Sciences, 1575
Brewer, Ralph : Awarded the United States National Reliability Award for 1958, 365 ; work of, 365
Brewer's Yeast : Endogenous Metabolism of Freshly Harvested Cells of a (V. E. Chester), 902
Brian, Dr. P. W. : Experimental Approaches to the Problems of Growth and Form in Plants (Morphogenetic Situations in which the Gibberellic Acids were involved), 585
Brian, Dr. P. W., and others : Effect of Gibberellic Acid on Development of Autumn Colour and Leaf-fall of Deciduous Woody Plants, 58
Brice, J. C. (Wright, H. C., and) : Indium Mono-Telluride, 27
Bricteux-Grégoire, Dr. S., and others : Utilization of the Carboxyl Group of Glycine for the Synthesis of the Amino-Acids of Silk by *Bombyx-mori*, *erratum*, 294
Bridgers, H. E., and others (edited by) : Transistor Technology, Vol. 1, *review* by Dr. J. R. Tillman, 72
Briggs, Prof. Asa : Appointed a member of the University Grants Committee, 86
Briggs, Dr. C. A. E. : Microbes and Milk, *review*, 637
Briggs, Dr. F. N. : Wheat Genetics, 25
Briggs, J. H., and others : A Presumptive Human *XXY/XX* Mosaic, 1030
Brightman, R. : Perkin Centenary—London, *review*, 709
  Information Service in Libraries, *review*, 781
  'Arms and the Man', *review*, 952
  Science and Society, *review*, 1702
Brighton Technical College : Residential Working Conference on Automatic Programming of Digital Computers, 438, 1779
Brill, Prof. R., and Zandy, H. : Absolute Measurement of the Intensity of the (111) Reflexion for Diamond, 1387
Brillouin, Prof. L. : Information Theory and its Applications to Fundamental Problems in Physics, 501
Brimble, L. J. F. : The Rockefeller Institute, New York—a New Graduate University, 1629
Brindley, Prof. G. W., and Nakahira, Dr. M. : Evidence for a Variable Long-range Order in nearly Anhydrous Gamma Alumina, 1620
Briner, G. P. (Johnstone, B.M., and) : Quantitative Estimation of Purines by the Visual Scanning of Photographs of Paper Chromatograms, 681
Brines (Fish and Meat Curing) : The Microbiology of—Proceedings of the Second International Symposium on Food Microbiology (Cambridge, 1957), (edited by Dr. B. P. Eddy), *review* by Dr. Magnus Pyke, 351
Brink, Prof. Frank : Elected a member of the United States National Academy of Sciences, 1575
Brinkhous, Prof. Kenneth M. (edited by) : Hemophilia and Hemophilioid Diseases—International Symposium, *review* by Prof. J. V. Dacie, 1221
Brinton, jun., Dr. Charles C. : Non-Flagellar Appendages of Bacteria, 782
Bristowe, Dr. W. S. : The World of Spiders, *review* by Dr. Eric Duffey, 1079
Britain : Bulk Production of Silicon in (Imperial Chemical Industries, Ltd.), 932
  Finance of Scientific Research in, 156
  Fuel and Power in (House of Lords Debate on), 511
  Funds for Commonwealth Students in, 793
  Future of Television in, 222
  Government Aid to Science in (House of Commons Debate on), 156
  Grants to Students in (National Union of Students Memorandum on), 864
  Increased Grants for Universities in, 507
  Industrial Health in, 867
  Inland Waterways in (House of Lords Debate on), 1305
  Library Services in, 1287
  Manufacture of Polypropylene in, 1162
  New Nature Reserves in, 1649
  Power Stations in, 794
  Preservation of the Countryside in, 917
  Production and Marketing of Radioactive Isotopes in, 720
  Reorganization of Industrial Microbiological Research in, 1
  Reorganization of Microbiological Research in (D. J. B. Copp), 416
  Research on Fuel and Power in, 507
  Scientific Man-power and Development in, 67
  Scientific and Technological Research in, 847
  Secondary Education in, 511
  Space Research in, 1231, 1302, 1568
  Trees of (Dr. Robert Gurney), *review* by Dr. F. N. Howes, 1627
  See also under Great Britain
British Agricultural History Society and the Economic History Society : Joint Conference on Agriculture and Rural Life, 582
British Army in the Second World War : Psychiatry in the (Dr. Robert H. Ahrenfeldt), *review* by Dr. D. Russell Davis, 208
British Association for the Advancement of Science : Science in Schools—Proceedings of a Conference under the auspices of the (London, 1958), (edited by W. H. Perkins), *review*, 211
  Granada Lectures (Communication in the Modern World), 293
  Formation by Section H of a special Committee to investigate the Denudation and Burial of Archaeological Structures, 1233
  Directory of Natural History and other Field Studies, 1723
British Association Looks Ahead (Prof. P. M. S. Blackett), 1569
British Association of Allergists (British Society for Immunology and the) : Symposium on the Immunological Aspects of Allergic Disorders, 296
British Association of Corrosion Engineers : Formation of, 1779
British Books and Information Services Overseas, 1417
British Broadcasting Corporation : Appointment of C. L. Boltz as Science Correspondent in the News Division, 1231
  Annual Grant of £5,000 for three years to the Council for Nature, for the establishment of an Intelligence Unit, 1231
  Reith Lectures (Prof. A. C. B. Lovell), *review* by Dr. R. A. Lyttleton, 1624

British Cast Iron Research Association : Retirement of Dr. J. G. Pearce from the directorship, 84
  Appointment of H. Morrogh as director, 84
  Open Days, 1434
British Cattle : The Nematodes *Ostertagia lyrata* Sjöberg, 1926, and *Trichostrongylus longispicularis* Gordon, 1933, in (Dr. J. H. Rose), 1745
British Coal Utilization Research Association : Open Days, 1024, 1786
British Commonwealth : Scientific Co-operation within the (H.R.H. the Duke of Edinburgh,) 425
British Commonwealth, Association of Universities of the : Report of the Executive Council for 1957-58, 1717
  Report of the Proceedings of the 1958 Home Universities Conference, 1764
British Compounding Ingredients for Rubber (compiled by Brian J. Wilson), *review* by Dr. W. J. S. Naunton, 779
British Computer Society, and others : Joint Symposium on Instrumentation and Computation in Process Development and Plant Design, 652
British Congress of Cosmetic Science (Society of Cosmetic Chemists), 934
British Council : Scholarships Abroad (1959-60), 650
  Annual Report for 1957-58, 659
British Council (Soviet Relations Committee), and the Soviet State Committee for Cultural Relations with Foreign Countries : Discussions on Anglo-Soviet educational and other exchanges, 582
British East African Waters : Marlins in (F. Williams), 762
British Embassies Overseas : Scientific Attachés on the staffs of, 16
British Embassy in Moscow : Appointment of D. A. Senior as scientific attaché, 1018
British Empire Cancer Campaign : Grant of £8,341 to the University of Bristol, for cancer research to be carried out in the Departments of Pathology, Physiology and Surgery, 581
British Fauna : A Monogenetic Trematode New to the (Z. Kabata), 481
British Fermentation Industries (J. M. Whitmarsh), *review*, 967
British Flora during 1958 (J. E. Lousley), 869
British Forestry : Progress in (Sir Harry Champion), 1100
British Gelatine and Glue Research Association : Sixteenth meeting of the Research Panel, 440
British Glaciological Society (Royal Astronomical Society and the) : Geophysical Discussion on Characteristics of the Antarctic Ice-Sheet, 1575
British Gold Medal for Aeronautics of the Royal Aeronautical Society awarded to R. S. Stafford, 1648
British Industry : Fuel and Power in (A. M. Wandless), 154
  Graduates in (Department of Scientific and Industrial Research), 864
British Institute of Management : Conference on Changing Industry, 655
British Institution of Radio Engineers : Election of Erik K. Cole as an honorary member, 582
  Convention on Television Engineering in Science, Industry and Broadcasting, 1234
British Iron and Steel Research Association (Iron and Steel Institute and the) : Translation Service of the, 224
British Journal of Psychology : Monograph Supplement 31, Figural After-Effects (Dr. Peter McEwen), 1027
British Manufacturing Industry, 1955 : Estimates of Resources devoted to Scientific and Engineering Research and Development in (Department of Scientific and Industrial Research), 847
British Marine Bottom Fauna : New Members of the (G. M. Spooner), 1695
British Marine Fishes, *review* by Dr. D. P. Wilson, 140
British Medical Bulletin, Vol. 15, No. 1, Recent Advances in Haematology, 1372
British Mineral Deposits : Isotopic Composition of Lead from (S. Moorbath), 595
British Museum : Retirement of Dr. H. J. Plenderleith from the keepership of the Research Laboratory, 791
  Appointment of Dr. A. E. A. Werner as keeper of the Research Laboratory, 792
British Museum (Natural History) : Appointment of W. A. Ferguson as secretary, 18, 154
  Nuffield Collection of Meteorites at the, 221
  Appointment of Dr. A. A. Moss as deputy keeper of the Department of Mineralogy, 1304
British National Committee on Antarctic Research : To co-ordinate British Antarctic Activities, 292
  Appointment of Sir Raymond Priestley as chairman, 292
British Nuclear Energy Conference (Institute of Physics, in collaboration with the) : Symposium on Nuclear Fuel Cycles, 1646
British Occupational Hygiene Society : Conference on the Control of Dust and Fumes in Industry, 865
British Plastics Federation : Conference on Reinforced Plastics, 24
British Polarographic Research Society : Course in Polarography, 18
British Rubber Manufacturers, Research Association of : British Compounding Ingredients for Rubber (compiled by Brian J. Wilson), *review* by Dr. W. J. S. Naunton, 779
British Scientific Attaché in Moscow, 1018
British Scientific Attachés Overseas, 16
British Scientific Film Association : Thirteenth Congress of the International Scientific Film Association, 1783
British Scientific Instrument Research Association : Establishment of an Electrical Instrument Test Service, 436
British Silver Medal for Aeronautics of the Royal Aeronautical Society awarded to D. J. Farrar, 1648
British Society for Immunology and the British Association of Allergists : Symposium on Immunological Aspects of Allergic Disorders, 296
British Society for the Philosophy of Science : Fourth Annual Conference, 1783
British Sociological Association (Scottish Branch) : Conference to mark the Centenary of 'The Origin of Species', 1562
British Spiders : Natural History of, *review* by Dr. Eric Duffey, 1079
British Standards Institution : B.S.3044, Anatomical, Physiological and Anthropometric Principles in the Design of Office Chairs and Tables (Dr. W. F. Floyd and Dr. D. F. Roberts), 1022
British Steel Industry, 222
British Trust for Ornithology : *Bird Migration*, Vol. 1, No. 1, 436
British Water Beetles (Prof. Frank Balfour-Browne), Vol. 3, *review* by Dorothy J. Jackson, 1420
Brittain, F. H. : Stereophonic Sound Recording, Reproduction and Broadcasting (Directional Hearing), 1720
Brittain, R. T., and others : Resolution of Chlorpheniramine and the Pharmacological Properties of its Isomers, 734
Broad Bean Seeds : Effect of Light on Maturing (Dr. G. R. Lane and R. D. Butler), 1063
Broadbent, Prof. T. A. A. : Legendre Functions, *review*, 1421
  Modern Tauberian Analysis, *review*, 1626
  Mathematics for the Physical Sciences, *review*, 1703
  Applied Analysis in the U.S.S.R., *review*, 1766
Broadcasting : Stereophonic Sound Recording, Reproduction and (Institution of Electrical Engineers Convention on), 1720
  Television Engineering in Science, Industry and (British Institution of Radio Engineers Convention on), 1234
Broadening of the X-Ray Diffraction Lines in Teeth affected by Fluorine (E. A. Scott and Dr. F. H. Scott), 479
Broadening (Dipolar), of Nuclear Magnetic Resonance Spectra of Solids : Removal of, by Specimen Rotation (Prof. E. R. Andrew, A. Bradbury and R. G. Eades), 1802
Broda, Prof. Engelbert : Radioaktive Isotope in der Biochemie, *review* by Dr. H. R. V. Arnstein, 1149
Brodie, Bernard B., and others : Cotinine, an Oxidation Product of Nicotine formed by Rabbit Liver, 47
Broecker, W. S., and others : Radiocarbon Measurements on Samples of Known Age, 1582
Bromides of Cadmium and Silver : Effects of Electron Bombardment upon (Sho Suzuki), 1755
Bromination of Dimethylaniline : Kinetic Isotope Effect in the (P. G. Farrell and Dr. S. F. Mason), 250
Bromination of Nucleic Acids and their Derivatives (A. S. Jones and D. L. Woodhouse), 1603
1,6-Di-(2-Bromoethylamino)-1,6-Dideoxy-D-Mannitol Dihydrobromide, a New Cytostatic Agent (L. Vargha and T. Horváth), 394
1,6-Di-(2-Bromoethylamino)-1,6-Dideoxy-D-Mannitol Dihydrobromide : Effect of, on Tumours of Laboratory Animals (Prof. J. Baló, G. Kendrey, J. Juhász and I. Besznyák), 395
Bronchial Cancer : Chemical Changes in Human Bronchial Epithelium and their relation to (J. Chayen, Prof. G. J. Cunningham and D. P. Winstanley), 1743
Bronchial Epithelium (Human) : Chemical Changes in, and their relation to Bronchial Cancer (J. Chayen, Prof. G. J. Cunningham and D. P. Winstanley), 1743
Bronchial Mucus Gel : Mucoprotein of (J. C. White, P. C. Elmes and W. Whitley), 1810
Bronk, Dr. Detlev W. (Waterman, Dr. Alan T., and) : The Argus High-Altitude Geophysical Experiments, 1019
Bronowski, Dr. J. : 'Darwinism and the Study of Society, 1563
Bronze Age : Life and Death in the (Sir Cyril Fox), *review* by M. C. Burkitt, 1486
Bronze Medal of the Royal Aeronautical Society awarded to D. G. King-Hele, 1648
Brook Trout : X-Ray Diffraction Patterns from the Egg Membrane of the Egg of the (Dr. Mamoru Kusa and Tsuguyasu Wada), 410
Brookhaven Medical Research Center : The Medical Research Reactor at the (Dr. E. E. Stickley), 1013
Brookhaven Symposium in Biology : Twelfth (Structure and Function of Genetic Elements), 1094
Brooks, J. D. : The Nature of Coal (Principal Chemical Methods of Investigating the Constitution of Coals), 1438
Brooks, Dr. John Langdon : The Systematics of North American *Daphnia*, 93
Brot, Dr. C. : Relaxation Processes (Dielectric Studies on Liquid Monoalcohols of Medium Chain-length), 584
Brown, A., and Norreys, J. J. : Beta-Polymorphs of Uranium and Thorium Disilicides, 673
Brown, Dr. A. E. : Of What Use is Acoustics to the Musician ?, 1294
Brown, Dr. A. F. : Elected a Fellow of the Royal Society of Edinburgh, 719
Brown, Annie M., and others : Measuring Productivity in Breeding of Small Animals, 339
Brown, Dr. A. W. A. : Insecticide Resistance in Arthropods, 1508
Brown, Dr. B. R. : Chemistry of Condensed Tannins (Acid-catalysed Polymerization of Phenolic Compounds), 1168
Brown, D. A. : Co-ordination Chemistry (Effect of Phenyl-substitution on the Stability of Sandwich Compounds), 1785
Brown, Dr. Donald D., and others : Enzymatic N-Methylation of Histamine, 680
Brown, Dr. E. H. : Appointed reader in structural analysis at the Imperial College of Science and Technology, 1571
Brown, F., and Graves, J. H. : Changes in Specificity and Electrophoretic Mobility of the Precipitating Antibodies present in the Serum of Cattle recovering from Foot-and-Mouth Disease, 1688
Brown, G. I. : An Introduction to Electronic Theories of Organic Chemistry, *review* by Dr. R. I. Reed, 279
Brown, I. D., and Dunitz, J. D. : Co-ordination Chemistry (The Cuprous-Diazoamino-benzene Complex), 1784
Brown, Dr. Juliet C. (Sewell, Dr. Geoffrey W. F., and) : Ecology of *Mucor ramannianus* Moller, 1344
Brown, Sir Lindor : Opening Address to the International Conference on Scientific Information (Desirability of Discipline and Restraint on the part of Authors of Scientific Papers), 147
Brown, L., and others : *α*-Helices and a New Polypeptide Fold in Poly-*β*-Benzyl-L-Aspartate, 1736
Brown, Paul K., and others : Action of Light on Visual Pigments—Vertebrate Lumi- and Meta-Rhodopsins, 442 ; Lumi- and Meta-Rhodopsins of Squid and Octopus, 446
Brown, Prof. R. : Elected a Fellow of the Royal Society of Edinburgh, 719
Brown, Dr. T. W. F. : *Obituary* of Sir Claude Gibb, 504
Brown Streak Virus (Cassava) : Mechanical Transmission of (R. M. Lister), 1588
Browning, B. H., and others : Inactivation of Organo-Mercurial Fungicides in Groundwood Pulp made from Logs stored in Salt Water, and the Possible Role of Sulphur Compounds, 1346
Bruce, Prof. F. M., and others : Gas Discharges (Spark, High-frequency and Glow Discharges), 93
Bruce (Dr. W. S.) Memorial Prize for 1958 awarded to Dr. Hal Lister, 1719
Brucella : Immunizing Properties of Insoluble Cell Material derived from (J. Markenson, D. Sulitzeanu and Prof. A. L. Olitzki), 1693
Brucker, W. M. : Replica of *Explorer I*, together with its *Jupiter*-C Carrier Rocket, presented to the Smithsonian Institution by, 510

Brumbaugh (Martin, G.) Lectures in Education—The Emergence of the Modern Mind (edited by Prof. Frederick C. Gruber), *review* by T. H. B. Hollins, 953
Brunel, Isambard Kingdom : Exhibition to commemorate the centenary of the death of (Engineering Laboratory, Cambridge), 1164
Brunner, Prof. William : *Obituary* by Prof. M. Waldmeier, 290
Bruno, M., and Croatto, Prof. U. : Structural Chemistry of Promethium, 601
Brunt, A. A.: Leaf-Enations in *Dahlia variabilis* Desf. induced by Tomato Spotted Wilt Virus, 627
Bubar, J. S. : Differences between Self-Incompatibility and Self-Sterility, 411
Buckell, Dr. Monamy, and Truscott, Margaret : Salt Concentration and Fibrinolytic Activity, 1268
Buckingham, Sue, and others : Bilirubin Metabolism in the Foetus, 1823
Buckland, F. E. : Impairment of Viral Haemagglutination of Red Cells after Treatment with Formalin, 1276
Bud Reactivation in *Splachnum ampullaceum* (L.) Hedw. : Interaction between Kinetin and Indoleacetic Acid in the Control of (Prof. K. E. von Maltzahn), 60
Buddington, A. F., and others : Magneto-striction and Palaeomagnetism of Igneous Rocks, 1318
Buds (Shoot), on the Protonema of *Pohlia mutans* : Effects of Kinetin, Gibberellic Acid and certain Auxins on the Development of (Dr. G. C. Mitra and Dr. A. Allsopp), 974
Bug (Mealy), *Planococcus citri* (Risso) : Triple Coitus in the (Walter A. Nelson-Rees), 479
Bugher, Dr. John C. : Appointed consultant on nuclear energy, Rockefeller Foundation, 1018
Building Research (Department of Scientific and Industrial Research to be the only Government Department with responsibility for), 94, 1367
Building Research, Studies and Documentation, International Council for : International Congress in Rotterdam, 1783
Bukovac, Prof. Martin J., and Davidson, Harold : Gibberellin Effects on Photoperiod-controlled Growth of *Weigela*, 59
Bulbil Formation in *Sedum telephium* (Dr. E. C. Humphries and J. M. Thurston), 1343
Bulbrook, R. D., and others : Changes in Œstrogen Titre in Stored Urine, 189
Bulge : The—its Industrial Impact (John Wellens), 1500
Bullard, Sir Edward : Automatic Reduction of Geophysical Data, 1167
Buller, Dr. A. J., and others : Fast and Slow Muscles in Mammals, 1516
Bulloch, R. S., and others : Nuclear Fuel Cycles (Perturbations due to Fuel Cycles), 1647
Bullough, Dr. R. : Interfacial Phenomena (Low-Energy Interfaces associated with Deformation Twins), 1098
Bullough, Dr. R., and others : Precipitation on a Dislocation, 34
Bulls : A Rare Sperm Abnormality—'Corkscrew-sperms' associated with Sterility in (Dr. Erik Blom), 1280
Bunn, Dr. C. W. : Relaxation Processes, 583
Bunt, Dr. J. S. : Marine Studies in the Inshore Waters of Antarctica near Mawson (1956), 1541
Bunton, Dr. C. A., and others: Oxidation of Ascorbic Acid and similar Reductones by Nitrous Acid, 163
Bur, Grato E., and others : Distribution of Alkaline Phosphatase in the Arteries of several Species, 1262
Burch, Dr. P. R. J. : Measurements at Leeds following the Windscale Reactor Accident—Iodine-131 in Human Thyroids and Iodine–131 and Caesium-137 in Milk, 515
Burchardt, Dr. F. A. : *Obituary* by K. G. J. C. Knowles, 577
Burden Neurological Institute, Bristol : Retirement of Prof. F. L. Golla from the directorship, 220
  Appointment of Dr. W. Ross Ashby as director, 220, 510
Burdin, M. L., and Prydie, J. : Lumpy Skin Disease of Cattle in Kenya, 949
Burges, Prof. Alan : Micro-organisms in the Soil, *review* by D. M. Webley, 1010
Burgess, B., and others : Deduction of Ionospheric Electron Content from the Fading of Signals from Artificial Earth Stellites, 1172
Burial of Archaeological Structures : Denudation and (Formation by Section H of the British Association for the Advancement of Science of a special Committee to investigate the), 1233
Burkard, Prof. O. : Radio Reflexions from the Moon and Solar Corona, 1180
Burkholder, Lillian M., and others : Chlorophyll *a* in some Corals and Marine Plants, 1338
Burkholder, Dr. Paul R., and others : Chlorophyll *a* in some Corals and Marine Plants, 1338
Burkitt, M. C. : Avian Folklore, *review*, 1422
  Reconstructing the Past, *review*, 1486
Burks, Arthur W. (edited by) : Collected Papers of Charles Sanders Pierce, Vol. 7, Science and Philosophy ; Vol. 8, Reviews, Correspondence and Bibliography, *review* by F. I. G. Rawlins, 276
Burn, Prof. J. H. : Retirement from the chair of pharmacology in the University of Oxford, 790 ; work of, 790
Burns, Dr. B. Delisle: Self-regulation in Living Systems (Knowledge of the Nervous System), 370
Burns, Tom : Darwinism and the Study of Society, 1562
Burnstock, Dr. G. : Elected to a Junior Fellowship by the Beit Memorial Trust, 1569
Burrow, Prof. H. : Advances in Veterinary Science, *review*, 1555
Burrows, Dr. E. M. : Experimental Approaches to the Problems of Growth and Form in Plants (Growth and Form of Algae), 585
Bursaries Scheme (Commonwealth) : Fifth Annual Report on the (Royal Society and Nuffield Foundation), 1304
Bursts (Metre-Wave and 3-cm. Wave) : Time Relationship of (M. R. Kundu), 1047
Burt, A. D., and Andrews, D. R. : Stereophonic Sound Recording, Reproduction and Broadcasting (Magnetic Tape Recording), 1720
Burton, Dr. A. : Self-regulation in Living Systems (Handling of Visual Information), 370
Busch, Suzanne, and others : Are Nucleoside Triphosphates Precursors of Mammalian Ribonucleic Acid *in vivo* ?, 1114
Bush, Prof. Douglas : Education in the Age of Science, 1436
Bushmen (Central Kalahari) : Blood-Group Investigation on (Dr. J. S. Weiner and Dr. A. Zoutendyk), 843
Bushmen (Kalahari) : The Nuffield—Witwatersrand University Expeditions to, 1958-59 (Prof. P. V. Tobias), 1011
Business : Electronic Computers in the Service of (W. L. C. Garrett), 11
Business Computer Symposium : Electronic Computer Exhibition and, 11
Business Machines Corporation (International), Cortlandt, New York : Appointment of Dr. Herman H. Goldstine as resident manager of the Lamb Estate Research Center, 1502
  Appointment of Dr. H. J. Greenberg as manager of the Mathematics Theory Department of the Lamb Estate Research Center, 1502
Busk (Edward) Memorial Prize of the Royal Aeronautical Society awarded to T. R. F. Nonweiler, 1648
Butler, Dr. H. E. : Elected a Fellow of the Royal Society of Edinburgh, 719
Butler, R. D. (Lane, Dr. G. R., and) : Experimental Approaches to the Problems of Growth and Form in Plants (Apical Development in relation to Etiolation), 585
  Effect of Light on Maturing Broad Bean Seeds, 1063
Butler, Warren L., and Siegelman, H. W. : Conversion of Caffeic Acid to Esculetin during Paper Chromatography, 1813
Buttery, S. : Detection of Antigens as Specific Precipitates on Paper Electrophoresis Strips, 686
γ-Butyrobetaine : Pharmacological Actions of (Dr. E. A. Hosein and Prof. H. McLennan), 328
Butzko, Robert L. : Plastic Sheet Forming, *review* by Dr. S. H. Pinner, 851
Byers, Horace R. : Grant of 383,700 dollars from the National Science Foundation, for research in cloud physics, covering the factors believed to be important in precipitation mechanisms, 1371
Byers, Horace R., and Braham, Roscoe, R. : Grant of 114,300 dollars from the National Science Foundation, for a study of the physical effects of silver iodide seeding over the Great Plains, 1371

CABLE, M. : Appointed lecturer in glass technology at the University of Sheffield, 1024
Cables (Electric) : Development of (S. E. Goodall), 226 ; (Prof. James Greig), 226
Cacao (Witch Broom Disease of) : Absence of Gibberellin-like Substances in Filtrates of *Marasmius perniciosus* Stahel (W. F. Dudman and R. Nichols), 899
Cade, C. M. : Awarded the Navigation Prize of the Royal Aeronautical Society, 1649
Cadmium Sulphide (Polycrystalline), and Polyethylene : Conductivity induced by Radiation in (C. G. Clayton, B. C. Haywood and Dr. F. J. Fowler), 1112
Cadmium and Silver : Effects of Electron Bombardment upon Bromides of (Sho Suzuki), 1755
Caeca (Genal), of Agnostids (A. A. Öpik), 1750
Caeruloplasmin from the *G2* Fraction of Human Plasma : Preparation of (Dr. G. Curzon and L. Vallet), 751
Caesium-137 in Milk : Iodine-131 in Human Thyroids and Iodine-131 and (Measurements at Leeds following the Windscale Reactor Accident), (Dr. P. R. J. Burch), 515
Caesium-137 in Dried Milk (D. V. Booker), 921
Caesium-137 in Swedish Milk and Soil (K. Löw and K. Edvarson), 1104
Caesium-Beam Standard of Frequency : Canadian (S. N. Kalra, R. Bailey and H. Daams), 575
Caffeic Acid to Esculetin : Conversion of, during Paper Chromatography (Warren L. Butler and H. W. Siegelman), 1813
Cagliotti, V., and co-workers : Co-ordination Chemistry (Preparation and Reduction of the Oxygen Adducts of Cobalt (II)–Histidine Complexes), 1785
Calcification (Aortic Medial), and Lowered Metabolism in Ground Squirrels (Dr. George R. Zimmerman and Prof. G. Edgar Folk, jun.), 754
Calcite Cleavage Faces : Etch Pits on (Dr. H. Watts), 314 ; (R. C. Stanley), 1548
Calcium : Micro Determination of (A. B. Gilbert), 888, 1754
  Separation of Strontium-90 from (P. S. Davis), 674
Calcium in Milk : Separation of Strontium-90 from (Dr. N. A. Myers), 1807
Calcium (Serum) : A Rapid Micro-quantitative Method for estimating (T. A. Harper), 232
Calcium Thymidylate : Crystal Structure of (P. Horn, Dr. V. Luzzati and Dr. K. N. Trueblood), 880
Calcium and Chloride Ion Contents and Protein Fractions in the Fluids of Chick Embryos : Sodium, Potassium, (Dr. Aleksandra Smoczkiewiczowa), 1260
Calculation of Erosion in Space from the Cosmic-Ray Exposure Ages of Meteorites (Dr. F. L. Whipple and Dr. E. L. Fireman), 1315
Calcutt, G. (Harper, K. H., and) : Glucuronide and Sulphate Conjugation *in vivo* and *in vitro*, 463
Caldecott, Dr. R. S. : Wheat Genetics, 27
Caldera (Kuttyaro) : Gravity Survey on the, by means of a Worden Gravimeter (Prof. Izumi Yokoyama and Hirokazu Tajima), 739
Caldin, Dr. E. F. : Observation and Interpretation, *review*, 1010
Caldwell, Prof. John : Persistence of Tomato Aucuba Mosaic Virus in Dried Leaf Tissue, 1142
Calendar : History of the (Y. G. Perel), 509
Calf : Lens Cells of the, in Continuous Culture (Dr. J. van der Veen and C. F. A. Heyen), 1137
Calf Serum (Precolostral) : Immunological Activity of (J. L. Turk), 838
Calicotyle : Relationship between *Dictyocotyle* and (Dr. J. Llewellyn), 835 ; (Dr. Ben Dawes and Dr. Ivor Griffiths), 835
California Institute of Technology : Grant of 73,594 dollars from the U.S. National Foundation to Dr. Renato Dulbecco, for investigations on virus inheritance in experiments involving polio virus mutations, 224
  Grant of 33,943 dollars from the U.S. National Foundation to Prof. Linus Pauling, for investigations on the structure of nucleic acids, 224
  Appointment of Dr. J. G. Bolton as first director of the newly established Radio Observatory, 506
Calkins, Dr. Evan (Cohen, Dr. Alan S., and) : Electron Microscopic Observations on a Fibrous Component in Amyloid of Diverse Origins, 1202
Callaghan, F. R. (edited by) : Science in New Zealand, *review*, 1010
Callely, A. G., and Dagley, Dr. S. : Biosynthesis of Cell Constituents from C_2-Compounds—Metabolism of Glycine by a Pseudomonad, 1793
Callerio, Dr. Carlo, and others : Antiviral Activity of Lysozyme, 548

Calliphora erythrocephala Meig.: Neurosecretion and Intestinal Proteinase Activity in an Insect (Ellen Thomsen and Ib Møller), 1401
Calverley, A., and Rhys, D. W. : Ductility of Rhodium, 599
Calves (Early Weaned) : A Relationship between some Bacteria, Protozoa and Diet in (J. Margaret Eadie, Dr. P. N. Hobson and S. O. Mann), 624
Calves (Monozygotic Twin) : Threshold Values for Taste in (Dr. F. R. Bell and H. L. Williams), 345
Calves (Young) : Changes in the Secretion of 20α-Hydroxypregn-4-en-3-one by the Adrenal Gland of (Dr. W. E. Balfour, Dr. R. S. Comline and R. V. Short), 467
Calvin, G., and others : Co-ordination Chemistry (Alkyl and Aryl Palladium Compounds), 1785
Calvin, Prof. Melvin : Elected a Foreign Member of the Royal Society, 1230, 1498 ; work of, 1498
Cambrian System ? : How Old is the (Prof. C. F. Davidson), 768 ; (Dr. K. I. Mayne, Dr. R. St. J. Lambert and D. York), 769
Cambridge Anthropology, *review* by Dr. Rodney Needham, 1625
Cambridge Instrument Co., Ltd. : New Research Laboratory, 293
Cambridgeshire : Crowned Cranes in (Simon B. Jones and Philip E. H. Jones), 560
Cameron, Christina, and Fletcher, K. : An Iodine Compound associated with Albumin in the Plasma of Thyrotoxic Patients, 116
Cameron, Sir Roy : Appointed secretary of the Beit Memorial Trust, 1569
Camp, M. (Shuttleworth, T. H., and) : Electron Microscopy of Sodium Laurate, 535
Campbell, A. G. : A Germination Inhibitor and Root-Growth Retarder in Chou Moellier (*Brassica oleracea* var.), 1263
Campbell, Dr. Dan H., and others : Passive Antibody Decay in Thyroidectomized Rabbits, 982
Campbell, Dr. J. Menzies : Apple-Scoops, 1542
Campbell, J. T., and Shalgosky, H. I. : X-Ray Spectrographic Determination of Strontium, 1481
Campolini, M., and co-workers : Co-ordination Chemistry (Stability of Metal Complexes—Heats of Formation of Ethylenediamine Complexes), 1784
Canada : Birds and Mammals of, 154
Canada (North-western) : Late Tertiary Geomagnetic Field in (P. M. Du Bois), 1617
Canada (United States and), East of the 100th Meridian : A Field Guide to Reptiles and Amphibians of the (Roger Conant), *review* by A. G. C. Grandison, 958
Canadian Caesium-Beam Standard of Frequency (S. N. Kalra, R. Bailey and H. Daams), 575
Canadian Department of Agriculture : Ninth International Botanical Congress, 1502
Canadian Fire Research Laboratory : New (R. F. Legget), 653
Canadian High Polymer Forum : Ninth (National Research Council of Canada, in co-operation with the Chemical Institute of Canada), 1643
Canadian Patents and Development, Limited : Forty-first Annual Report of the National Research Council of Canada (1957-58), including the Annual Report of, 441
Canadian Society of Plant Physiologists : Election of Officers, 933
Canalization of Development and Genetic Assimilation of Acquired Characters (Prof. C. H. Waddington), 1654
Cancer : Contribution of Electron Microscopy of Viruses and Cells to the Problem of (Electron Microscope Society of America Symposium on), 1719
  Papers presented at the Conference on the Genetic Concept for the Origin of (Annals of the New York Academy of Sciences, Vol. 71), 1234
  Surmise and Fact on the Nature of (Dr. Peyton Rous), 1357
Cancer (Bronchial) : Chemical Changes in Human Bronchial Epithelium and their relation to (J. Chayen, Prof. G. J. Cunningham and D. P. Winstanley), 1743
Cancer (Human Breast) : Variables related to (A. Elving Anderson, Harold O. Goodman and Sheldon C. Reed), *review* by Dr. L. Foulds, 955
Cancer (Mammary) : Proceedings of the Second International Symposium on, held at Perugia, 1957 (edited by Lucio Severi), *review* by Dr. L. Foulds, 955
Cancer Campaign, British Empire : Grant of £8,341 to the University of Bristol, for cancer research to be carried out in the Departments of Pathology, Physiology and Surgery, 581
Cancer Cells : Aminopeptidase Activity in (R. G. J. Willighagen and H. T. Planteydt), 263
Cancer Research : Clinical and Experimental, *review* by Dr. L. Foulds, 955
Candy, D. J., and Kilby, Dr. B. A. : Site and Mode of Trehalose Biosynthesis in the Locust, 1594
Canning, Dr. Elizabeth U. : Systematic and Experimental Studies on Protozoal Blood Parasites of Egyptian Birds, *review*, 1081
Cannon, Dr. Peter : Melting Point and Sublimation of Molybdenum Disulphide, 1612
Canny, M. J., and others : Metal-Chelating Porperties of Plant-Growth Substances, 1176
Cano Ruiz, J., and others : β-Type Interlamellar Sorption Complexes, 740
Capillaries (Glass) : An Equation for the Flow of Blood, Plasma and Serum through (Dr. G. W. Scott Blair), 613
Capillary Columns (Nylon), for use in Gas–Liquid Chromatography (R. P. W. Scott), 1753
Capital Investment in the Coal, Electricity and Gas Industries : White Paper on, 1651
Cappell, Prof. D. F. : *Obituary* of Sir Robert Muir, 1363
Caputo, A., and others : Oxygen Equilibrium of Human Haemoglobin in Strong Salt Solutions, 827
Carbide : Silicon (United States Air Force Cambridge Research Center Conference on), 722
Carbohydrate Chemistry : Topics in, *review* by Prof. M. Stacey, 1219
Carbohydrate Complexes : Methanol-soluble (Ernest H. Freund and Kelvin Domovs), 1526
Carbohydrate Constituents of the Mycelium of *Penicillium chrysogenum* grown in Media with Different Sources of Carbon (Roshan J. Irani and Dr. K. Ganapathi), 758
Carbohydrates—Chemistry, Biochemistry, Physiology (edited by Ward Pigman), *review* by Prof. M. Stacey, 1079
Carbohydrates Complete, *review* by Prof. M. Stacey, 1079
Carbohydrates, Hydroxyacids and Amino-acids in Aqueous Solutions : Effects of Gamma-Radiation on some (Dr. S. A. Barker, Dr. P. M. Grant, Prof. M. Stacey and Dr. R. B. Ward), 376
Carbon : Carbohydrate Constituents of the Mycelium of *Penicillium chrysogenum* grown in Media with Different Sources of (Roshan J. Irani and Dr. K. Ganapathi), 758
C_2-Compounds : Biosynthesis of Cell Constituents from—Formation of Malate from Glycollate by *Pseudomonas ovalis* Chester (Dr. H. L. Kornberg and A. M. Gotto), 1791 ; Metabolism of Glycine by a Pseudomonad (A. G. Callely and Dr. S. Dagley), 1793 ; Formation of Glycerate from Oxalate by *Pseudomonas oxalaticus* (OX1) grown in Oxalate (J. R. Quayle and Dr. D. B. Beech), 1794
Carbon-14 : Effect of Streptomycin on the Incorporation of Amino-Acids labelled with, into Ribonucleic Acid and Protein in a Cell-free System of a *Mycobacterium* (T. Erdös and Agnes Ullmann), 618
  Synthesis of Dextran Sulphate labelled with, and Tracer Experiments in the Rat (Dr. H. Weigel and Dr. K. Walton), 981
C_{18} and C_{19} *Cyclo*propane Fatty Acids : Structure of Malvalic Acid and some related (Dr. B. Craven and Prof. G. A. Jeffrey), 676
Carbon (Organic) : Role of Poly-β-Hydroxybutyric Acid in the Assimilation of, by Bacteria (Prof. M. Doudoroff and Prof. R. Y. Stanier), 1440
Carbon Dioxide : Gas–Chromatographic Observation of the Reduction of, to Methane during Anaerobic Digestion (J. Chmielowski and Peter C. G. Isaac), 1120
Carbon Dioxide in *Kalanchoe blossfediana* : Dark Fixation of, in relation to Photoperiodism (Dr. G. Zabka, Prof. F. G. Gregory and Dr. J. Edelman), 1375
Carbon Monoxide Content of the Blood and other Observations on Weddell Seals (Dr. L. G. C. E. Pugh), 74
Carbon Monoxide Pressure : Behaviour of Dicobalt Octacarbonyl at Elevated Temperature and (Sol Metlin, Irving Wender and Heinz W. Sternberg), 457
Carbon Steels (Plain) : Structure of Scale on (Dr. S. Garber), 1387
Carbonatite Magma : Synthetic (Prof. P. J. Wyllie and O. F. Tuttle), 770
Carbone, J. V., and others : Metabolism of Sulphobromophthalein, 469
Carbonic Acid : Selective Permeability of Living Tissues to (Dr. B. N. Halpern and R. Binaghi), 1397
Carboxyl Group of Glycine : Utilization of the, for the Synthesis of the Amino-Acids of Silk by *Bombyx mori* (Dr. S. Bricteux-Grégoire, W. G. Verly and Prof. M. Florkin), *erratum*, 294
Carcinogen (Chemical) : Response of Newly Born Mice to a (Giuseppe Pietra, Kathryne Spencer and Prof. Philippe Shubik), 1689
Carcinogenesis (Ultra-violet), in Albino and Pigmented Mice receiving Furocoumarins—Psoralen and 8-Methoxypsoralen (M. A. Pathak, Prof. F. Daniels, jun., C. E. Hopkins and T. B. Fitzpatrick), 728
Carcinogenic Azo Dye : Prevention of Adaptive Formation of Tryptophan Peroxidase by a (Dr. Silvio Fiala and Anna E. Fiala), 1532
Carcinoma of the Lung (edited by J. R. Bignall), *review* by Dr. L. Foulds, 955
Carcinoma of the Uterine Cervix : Virus-like Particles in Chemically induced (Dr. M. Thiery, Dr. M. De Groodt, Prof. F. De Rom, Prof. M. Sebruyns and Dr. A. Lagasse), 694
Carcinoma Agent (Mouse Mammary) : Purification of the, by means of a Fluorocarbon (Robert S. Stone and Prof. Dan H. Moore), 1275
Carcinoma Cells (Ehrlich Ascites) : Energy Compensation in the Crabtree Effect with (K. H. Ibsen, E. L. Coe and Dr. R. W. McKee), 1471
Carcinus maenas Pennant : Behaviour of Sacculinized Shore Crabs (Erik Rasmussen), 479
Cardiac Activity : Nucleotide Metabolism in (Dr. Philip A. Khairallah), 181
Cardiac Muscle Fibres : Relation of Extracellular to Intracellular Potential Records from Single (Dr. E. M. Vaughan Williams), 1341
Cardiac Output in Cattle (Edward W. Fisher and Rodger G. Dalton), 829
Cardiolipin : Position of the Fatty Acids in (Dr. Marjorie G. Macfarlane and L. W. Wheeldon), 1808
Care, A. D., and others : Equilibration of Labelled Magnesium between Sheep Plasma and Red Cells, 1265
Careers Exhibition : National Education and (National Union of Teachers), 794
Careers (Scientific), in the Ministry of Supply, 651
Carey, G. C. R. : Appointed to a lectureship in preventive medicine at the Queen's University, Belfast, 86
Carlisle, Dr. C. H. : Title of reader in crystallography in the University of London (at Birkbeck College) conferred on, 794
Carlisle, Dr. D. B., and Jenkin, Dr. Penelope M. : Terminology of Hormones, 336
Carlsberg–Wellcome Travelling Research Scholarships, 1024
Carmichael, Charles M. : Remanent Magnetism of the Lake Allard Ilmenites, 1239
Carnazzo, Anthony J., and others : Target Organ Activation by Stress, 1522
Carnegie (Andrew) Silver Medal for 1958 of the Iron and Steel Institute awarded to Dr. P. Vasudevan, 930
Carnegie Institution of Washington : Year Book No. 57 (1957-1958), 1025
Carney, G. C. : Differential Response of Male and Female Adults of *Trogoderma granarium* Everts towards Sterilizing Doses of Gamma-Radiation, 338
Carotene Content of *Ulex europaeus* (Common Furze), (Dr. D. G. O'Donovan, U. O'Leary and Prof. J. Reilly), 1680
Carotenoid Pigment in *Spirabacillus cienkowskii* Metchnikoff, a Pathogen of Cladocera (J. Green), 56
Carotenoids in *Phycomyces* : Effects of Starvation and Diphenylamine on (T. N. R. Varma, Prof. C. O. Chichester and G. Mackinney), 188
Carr, Dr. Francis H. : Awarded the Society Medal for 1959 of the Society of Chemical Industry, 722
Carr, T. D., and others : Anomalous Night-Time Reception of a Major Solar Radio Burst, 597
Carrier Gas : Effect of, on Katharometer Response (W. A. Wiseman), 1321
  Effect of the, on the Sensitivity of a Thermal-conductivity Detector in Gas Chromatography (L. J. Schmauch and R. A. Dinerstein), 673 ; (Dr. N. H. Ray), 674
  Effect of the, on the Sensitivity of Thermal Conductivity Detectors in Gas Chromatography (Dr. B. A. Scott and Dr. A. G. Williamson), 1322
Carriers in Hereditary Galactosaemia : Detection of (Dr. Herman M. Kalckar), 1266
Carriers (Heterozygous) : Detection of, in Glycogen Storage Disease of the Liver (von Gierke's Disease), (Dr. David Yi-Yung Hsia and Eva Gawronska Kot), 1331

Carron, W. J. : Industry and the Individual (Role of the Trade Unionist in relation to Productivity and the Rights of the Individual), 88
Carruthers, Dr. J. N., and others : Shorewards Upslope of the Layer of Minimum Oxygen off Bombay—its Influence on Marine Biology, especially Fisheries, 1084
Carson, A. W., and others : Electrode Potentials and Compound Formation in the Palladium–Platinum–Hydrogen System, 39, 510
Carson, John F., and Wong, Francis F. : A Colour Reaction for Thiolsulphinates, 1673
Carter, G. : Dual Pumping Speeds of some Ionization Pumps, 1619
Carter, M. V. : Chemical Destruction of Mature Perithecia of *Mycosphaerella pinodes*, 162, *erratum*, 438
Carthy, Dr. J. D. : An Introduction to the Behaviour of Invertebrates, *review* by Dr. G. A. Horridge, 4
Cartilage : Oxidative Metabolism of (Dr. Philip Person and Dr. Albert Fine), 610
  Trichloracetic Acid-insoluble Phosphate Compounds in (R. G. Whitehead and Dr. S. M. Weidmann), 876
Cartilage (Epiphyseal), during Rickets : Histochemical Changes in the (Prof. J. T. Irving), 1734
Cartilage (Human) : Ageing of (David Kaplan and Dr. Karl Meyer), 1267
Cartilage (Rachitic Rat) : Influence of Vitamin D on Synthesis of Hexosamine by (P. K. Dikshit), 334
Carvalho, Dr. Alcides : Preliminary Information on the Genetics of Ethiopian Coffees, 906
Case, James D., and others : Melatonin in Peripheral Nerve, 1821
Case, Prof. L. C. : Equilibration of *iso*Cyanates and *iso*Thiocyanates, 675
Case, Prof. L. C. (Schmoyer, L. F., and) : A Simple Synthesis of Oxetanes, 389
Casease in *Entamoeba histolytica* (Prof. Mitsuru Nakamura and Philip R. Edwards, jun.), 397
κ-Casein : Distribution of, in Skim Milk (Royal A. Sullivan, Margaret M Fitzpatrick and Elizabeth M. Stanton), 616
Casework : Spectral, *review* by Dr. D. J. West, 351
Cassava : A Two-stage Fermentation of (Prof. Patrick Collard and Simon Levi), 620
Cassava Brown Streak Virus : Mechanical Transmission of (R. M. Lister), 1588
Cassels, Prof. J. M. : Elected a Fellow of the Royal Society, 860
Casselton, P. J. : An Effect of Yeast Extract on the Growth of *Chlorella*, 1404
Cassen, R. H. : Awarded a Harkness Fellowship for 1959 by the Commonwealth Fund, 1093
Cassie, Dr. A. B. P. : Report for 1958 of the Wool Industries Research Association, 1781
Casson, Sir Lewis : Elected to Fellowship of the Imperial College of Science and Technology, 1161
Cast Iron Research Association, British : Retirement of Dr. J. G. Pearce from the directorship, 84
  Appointment of H. Morrogh as director, 84
  Open Days, 1434
Cat's Retinal Ganglion Cells : Recording Inhibition and Excitation in the, with Intracellular Electrodes (Dr. Torsten N. Wiesel), 264
Catabolism (Glucose), in the Mammary Gland of the Rat : Effect of Insulin and Phenazine Methosulphate on Pathways of (P. McLean), 182
Catala-Stucki, Dr. R. : Fluorescence Effects from Corals irradiated with Ultra-Violet Rays, 949
Catalysing Ester Hydrolysis : Role of Lysine in (William R. Chesbro and Prof. Leslie R. Hedrick), 994 ; (Alexander Gero), 994
Catalysis (Surface) : A Chromatographic Technique for Studying the Mechanism of (Kenzi Tamaru), 319
Catalysts (Oxide) : Effect of Thermal Neutron Irradiation on, for the Decomposition of Nitrous Oxide (Yasukazu Saito, Yukio Yoneda and Shoji Makishima), 388
Catalytic Action of Copper in the Alkaline Autoxidation of Cellulose at Low Alkali Concentration (R. I. C. Michie and Dr. S. M. Neale), 534
Catches (Trawl), from the Sierra Leone River Estuary : Seasonal and Tidal Fluctuations in the (J. C. D. Watts), 1748
Catechol in Human Urine : Excretion of (Prof. U. S. von Euler and F. Lishajko), 1123
Cater, Dr. D. B., and Weiss, Dr. L. : Measurements of Oxygen Tension in the Tissues of Mice cooled to 1°C., 1521
Cathode Inclusions : Effect of, on Electrical Discharges (P. C. L. Pfeil and L. B. Griffiths), 1481
Cathode-Ray Tube : The Ferranti 5/71 *CM* Micro-Spot, 1642
Cathode Spots (Vacuum Arc) : An Effect of Oxide Layers on the Behaviour of (H. Wroe and R. H. Alderson), 1544
Cathode (Hollow-) Emission of the A10 Spectrum (V. Wilson Goodlett and K. Keith Innes), 243
Cations (Alkali) : Absorption of, by Plant Tissue Cultures (Dr. J. F. Sutcliffe and E. R. Counter), 1513
Catskill Delta : *Spirifer disjunctus*, its Evolution and Paleoecology in the (Hugo Greiner), *review* by Dr. H. M. Muirwood, 959
Cattala, L. (Roche, Dr. A., and) : Remanent Magnetism of the Cretaceous Basalts of Madagascar, 1049
Cattell, Prof. Raymond B. : Personality and Motivation Structure and Measurement, *review* by Prof. M. D. Vernon, 140
Cattle : Bloat in (Dr. M. J. Head), 757
  Breeding 10,000,000 (Milk Marketing Board), 1641
  Cardiac Output in (Edward W. Fisher and Rodger G. Dalton), 829
  β-Globulin Polymorphism and Early Foetal Mortality in (Dr. G. C. Ashton), 404
Cattle (British) : The Nematodes *Ostertagia lyrata* Sjöberg, 1926, and *Trichostrongylus longispicularis* Gordon, 1933, in (Dr. J. H. Rose), 1745
Cattle in Kenya : Lumpy Skin Disease of (M. L. Burdin and J. Prydie), 949
Cattle recovering from Foot-and-Mouth Disease : Changes in Specificity and Electrophoretic Mobility of the Precipitating Antibodies present in the Serum of (F. Brown and J. H. Graves), 1688
Caudal Regeneration in some Errant Polychaetes : Role of the Supraoesophageal Ganglion during the Early Stages of (Dr. R. B. Clark and M. E. Clark), 1834
Causes (Possible), of Geomagnetic Fluctuations having a 6-Sec. Period (H. J. Duffus, J. A. Shand and Sir Charles Wright), 1479, *erratum*, 1783
Cave Deposits : The Transvaal Ape-Man-bearing (C. K. Brain), 1433
Caves (Niah Great) : 'Bat Erosion' at (Tom Harrisson and Lord Medway), 971
Cayless, M. A. : Gas Discharges (Factors governing the Shape and Size of the Glow and the Electron and Ion Currents at the Cathode Surface), 92
Cell : Effect of X-Rays on the (Dr. M. Silha), 1531
  Physical and Chemical Exploration of the, *review* by Dr. R. Barer, 1355
Cell (Gastric Parietal) : Functional Changes in the Vacuole-containing Bodies of the (A. D. Hally), 408
Cell (Human Red) : Haemoglobin and 'Apparent Protein' in the (Dr. Eric Ponder), 1330
Cell Constituents from C_2-Compounds : Biosynthesis of—Formation of Malate from Glycollate by *Pseudomonas ovalis* Chester (Dr. H. L. Kornberg and A. M. Gotto), 1791 ; Metabolism of Glycine by a Pseudomonad (A. G. Callely and Dr. S. Dagley), 1793 ; Formation of Glycerate from Oxalate by *Pseudomonas oxalaticus* (OX1) grown in Oxalate (J. R. Quayle and Dr. D. B. Keech), 1794
Cell Dimensions : Variation in Etch Behaviour of Jacobsite with Different (Dr. Supriya Roy), 1256
Cell Division : Phagocytosis and (Klaus G. Bensch, Stanley Simbonis, Rolla B. Hill, jun., and Prof. Donald W. King), 476
Cell 'Ghosts' (Red) : Preparation and the Haemoglobin Content of (Helen M. Anderson and Dr. Joseph C. Turner), 112
Cell Growth and the Development of Tumours (Anna Kane Laird and A. D. Barton), 1655
Cell Haemolysates (Red) : Demonstration of Small Components in, by Starch-gel Electrophoresis (Dr. Phaedon Fessas and N. Mastrokalos), 1261
Cell Material (Insoluble), derived from *Brucella* : Immunizing Properties of (J. Markenson, D. Sulitzeanu and Prof. A. L. Olitzki), 1693
Cell-Nuclei in the Adrenal Medulla : Deoxyribonucleic Acid Content of the, after Exposure to Low Temperatures (L. Leeman), 1188
Cell-Wall Composition of *Leptotrichia* spp. (Dr. G. H. G. Davis and A. C. Baird-Parker), 1206
Cell Walls (Aberrant), and of Spores : Formation of, by the Growing Yeast Protoplast (A. A. Eddy and D. H. Williamson), 1101
Cell-free System of *Mycobacterium* : Effect of Streptomycin on the Incorporation of Amino-Acids labelled with Carbon-14 into Ribonucleic Acid and Protein in a (T. Erdös and Agnes Ullmann), 618
Cells : Contribution of Electron Microscopy of Viruses and, to the Problem of Cancer (Electron Microscopy Society of America Symposium on), 1719
  A Correlation between Iodine Permeability and the Gram Characteristic of (Prof. J. W. Bartholomew, Thomas Cromwell and Harold Finkelstein), 123
  The Motility of Muscle and (Prof. Hans H. Weber), *review* by J. R. Bendall, 278
Cells (Ascites Tumour) : Micro-Electrode Penetration of (B. M. Johnstone), 411
Cells (Cancer) : Aminopeptidase Activity in (R. G. J. Willighagen and H. T. Planteydt), 263
Cells (Cat's Retinal Ganglion) : Recording Inhibition and Excitation in the, with Intracellular Electrodes (Dr. Torsten N. Wiesel), 264
Cells ('Chloride-Secretory'), in the Gills of Teleosts (Gwyneth Parry, and F. G. T. Holliday and J. H. S. Blaxter), 1248
Cells (Chromaffin) : A New Type of, probably storing Dopamine (Bengt Falck, Prof. Nils-Åke Hillarp and Alf Torp), 267
Cells (Circulating), of Infectious Mononucleosis : Incorporation of Thymidine labelled with Tritium by (Dr. F. Gavosto, A. Pileri and G. Maraini), 1691
Cells (Ehrlich Ascites Carcinoma) : Energy Compensation in the Crabtree Effect with (K. H. Ibsen, E. L. Coe and Dr. R. W. McKee), 1471
Cells (Epidermal), in Petioles of Strawberry : Effect of Gibberellic Acid on Length and Number of (C. G. Guttridge and P. A. Thompson), 197
Cells (Freshly Harvested), of a Brewer's Yeast : Endogenous Metabolism of (V. E. Chester), 902
Cells (Ganglion), in the Retina of Anurans : Number of Fibres in the Optic Nerve and the Number of (Dr. H. R. Maturana), 1406
Cells (Human Red) : Effect of Ouabain on Sodium Flux in (Thomas J. Gill and Prof. A. K. Solomon), 1127
Cells (Isolated Spleen), transferred to Recipients in Absence of Homotransplantation Reaction : Antibody Formation by (Dr. Z. Trnka and I. Říha), 546
Cells (Lens), of the Calf in Continuous Culture (Dr. J. van der Veen and C. F. A. Heyen), 1137
Cells (Living) : Prevention of Freezing Damage to, by Dimethyl Sulphoxide (Dr. J. E. Lovelock and Dr. M. W. H. Bishop), 1394
Cells (Mammalian) : Two Types of Ribonucleoprotein in the Nucleolus of (Dr. Robert Love and Dr. T. P. Bharadwaj), 1453
Cells (Mammalian), irradiated *in vivo* : A Survival Curve for (Dr. H. B. Hewitt and C. W. Wilson), 1060
Cells (Mast) : Analysis of, by means of Polarization Microscopy (Prof. Leslie Horváth), 1067
  Differences in Mechanism in Staining Reactions for (Dr. Harold M. Fullmer), 1274
  Leucine Aminopeptidase Activity in (Dr. O. Braun-Falco and Dr. K. Salfeld), 51
Cells (Normal and Malignant), cultivated in Synthetic Media : Glutamine Metabolism of (Arthur E. Pasieka and Dr. Joseph F. Morgan), 1201
Cells (Pineal Eye Sensory) : Ultrastructure of (Dr. W. Steyn), 764
Cells (Red) : Equilibration of Labelled Magnesium between Sheep Plasma and (A. D. Care, D. C. Macdonald and B. Nolan), 1265
  Impairment of Viral Haemagglutination of, after Treatment with Formalin (F. E. Buckland), 1276
Cells (Red), of the Mouse after Treatment with Formalin : Increase of Viral Haemagglutinability of (B. Fauconnier and D. Barua), 629
Cells (Red Blood) : Rate of Exchange of Phosphate in—Effect of Thyroid Hormones (A. M. Ermans and Prof. P. A. Bastenie), 679
Cells (Reticular) : Re-utilization of Lymphocyte Remnants by (Dr. M. Hill), 1059
Cells (Tissue Culture), stained with Acridine Orange : Fluorescence of (U. N. Joshi and Dr. K. S. Korgaonkar), 400
Cells (Transferred) : Presence of Antigen—a Factor determining the Duration of Antibody Formation by (Dr. J. Sterzl), 547
Cells (Yeast) : Life Span of Individual (Robert K. Mortimer and John R. Johnston), 1751
Cells and Spores (Vegetative), of *Bacillus cereus* and *Bacillus megaterium* : Differences in Cyst(e)ine Content between (Vladimír Vinter), 998

Cellulose : Synthesis of, in Ethanol Extracts of *Acetobacter xylinum* (Dr. J. Ross Colvin), 1135
Cellulose at Low Alkali Concentration : Catalytic Action of Copper in the Alkaline Autoxidation of (R. I. C. Michie and Dr. S. M. Neale), 534
Cellulose containing Methyl Groups : Changes produced in Serum Lipoproteins of Dogs by (Margaret M. Fröhlich, V. Balázs, K. Kovács and A. Benkö), 1119
Cellulose-reactive Dyes : Labelling of Proteins with (Dr. R. Hess and Dr. A. G. E. Pearse), 260
Cellulose Acetate as a Medium for Immuno-Diffusion (R. Consden and J. Kohn), 1512
Cellulose Acetate Membranes suitable for Osmotic Measurements (M. F. Vaughan), 43
Cellulose Acetate Membranes used for Zone Electrophoresis : Regeneration of (Dr. S. Jacobs), 1326
Cellulosics (Walter D. Paist), *review* by Dr. S. H. Pinner, 851
Cement (Hardened Portland), during Testing : Errors caused by Partial Drying of (Dr. K. M. Alexander), 885
Centenaries of 1959 : Scientific (Joan M. Eyles), 12
Centenary of the death of Isambard Kingdom Brunel : Exhibition to commemorate the (Engineering Laboratory, Cambridge), 1164
Centenary of the Formulation of the Theory of Evolution by Charles Darwin and Alfred Russel Wallace and the Bicentenary of the publication of the tenth edition of the 'Systema Naturae' by Linnaeus (Congress in Singapore to celebrate the), 723
Centenary of the Royal Society of Victoria, 86
Central Advisory Water Committee : Fourth Meeting, 152
  Appointment of Prof. J. Proudman as chairman of the Sub-Committee on the Demand for Water, 152
Central Africa : Scientific Research in, 1718
Central Fuel Research Institute, India : Symposium on the Nature of Coal, 86, 1438
Central Nervous System : Persistence of Cholesterol-4-^{14}C in the (Dr. A. N. Davison and Martha Wajda), 1606
Central Organisation for Defence (White Paper on), 1483
Centre d'Etudes Nucléaires de Grenoble, 858
Centre Européen des Federations de l'Industrie Chimique, 1368
Century of Biological Research (Illinois Natural History Survey, Bulletin, Vol. 27), 1233
Cephalopods : Cephalotoxin, the Crab-paralysing Agent of the Posterior Salivary Glands of (Dr. F. Ghiretti), 1192
Cephalotoxin, the Crab-paralysing Agent of the Posterior Salivary Glands of Cephalopods (Dr. F. Ghiretti), 1192
Ceramic Materials (Fired) : Adsorption and Desorption of Moisture in (F. Vaughan and A. Dinsdale), 600
Cercaria : A New Leech-infesting, from Duddingston Loch, Edinburgh (Prof. M. B. Lal), 697
Cereal Research Station (German) : Annual International Starch Convention, 510
Cerebellum : Physiology of the, *review* by Dr. C. G. Phillips, 954
  The Physiology and Pathology of the (Prof. Robert Stone Dow and Prof. Giuseppe Moruzzi), *review* by Dr. C. G. Phillips, 954
Cerebral Circulation and Metabolism in a Pyridoxine-dependent Child : Effects of Pyridoxine Withdrawal on (Dr. Louis Sokoloff, Dr. Niels A. Lassen, Dr. Guy M. McKhann, Dr. Donald B. Tower and Dr. Wayne Albers), 751
Cerebral Cortex : Electron Microscopy of Synaptic Contacts on Dendrite Spines of the (Dr. E. G. Gray), 1592
  Recurrent Inhibition in (Dr. Roger M. Morrell), 979
CERN (European Organization for Nuclear Research) : Annual Report for 1957, 21
  International Conference on High Energy Accelerators and Instrumentation, 1783
Cerrai, E., and Gadda, F. : Separation of Mono-*n*-butyl Phosphate and Di-*n*-butyl Phosphate by means of Ion Exclusion, 1528
Ceruloplasmin : Preparation of (Dr. M. Steinbuch and M. Quentin), 323
Cervix (Uterine) : Virus-like Particles in Chemically induced Carcinoma of the (Dr. M. Thiery, Dr. M. De Groodt, Prof. F. De Rom, Prof. M. Sebruyns and Dr. A. Lagasse), 694
Chabanaud, Dr. Paul : *Obituary* by Dr. E. Trewavas, 1496
Chabbi, Lamine : The Role of the Scholar in Society, 1772
Chaffinch (Common), *Fringilla coelebs* Linn. : Singing Pattern of the (D. R. Barber), 129
Chain, Prof. E. B., and others : Penicillin Derivatives of *p*-Aminobenzylpenicillin, 180, *erratum*, 224
Chain Fracture : Estimation of, during the Cross-linking of Rubber Hydrocarbons by High-Energy Radiation (Dr. L. Mullins and Dr. D. T. Turner), 1547
α-Chains of Adult and Foetal Human Haemoglobins : Identity of the (J. A. Hunt), 1373
Chairs and Tables (Office) : Anatomical, Physiological and Anthropometric Principles in the Design of (Dr. W. F. Floyd and Dr. D. F. Roberts), 1022
Chaklader, A. C. D., and Roberts, Prof. A. L. : Sintering of Quartz Crystal, 1252
Chakrabartty, S. K., and others : The Nature of Coal (Pyrolysis and its relation to the Structural Parameters of Coal), 1439
Challenger Society : Grants for research in Marine Biology or Oceanography, 1368
Chalmers, Dr. J. N. Marshall, and Shinton, N. K. : Effect of D-Sorbitol on the Absorption of Orally Administered Vitamin B_{12}, 120
Chamberlin, Prof. Ralph V., and Gertsch, Willis J. : The Spider Family Dictynidae in America North of Mexico, 1170
Champion, Sir Harry : Retirement as professor of forestry in the University of Oxford, 578 ; work of, 578
  Progress in British Forestry, 1100
  Forestry in the United Kingdom, 1238
Chance and Skill in Gambling : Preferences for Different Combinations of (Prof. John Cohen and C. E. M. Hansel), 841
Chance-Pilkington Optical Works : Radiation-absorbing Glasses, 292
Chandler, Dr. B. V., and Swain, Dr. T. : Separation of Anthocyanins from Plant Extracts, 989
Change of Colour in Frogs : Serotonin and (Dr. K. G. Davey), 1271
Change in Permeability effected by Lipid-soluble Analogues of Acetylcholine : Distinction between Sodium and Potassium in (Dr. Wolf D. Dettbarn), 465
Change (Dietary), in *Harmolita hyalipenne* Walker : Facultative Parasitism and (R. Bailey), 341
Change (Social) : Social Policies and, *review* by M. P. Hall, 1147
Changes in the Electron Spin Resonance Spectrum of Glycine with Increasing Doses of Radiation (Dr. J. W. Boag and A. Müller), 831
Changes in the Group A Antigen in a Case of Leukaemia (Dr. E. R. Gold, Dr. Geoffrey H. Tovey, W. E. Benney and F. J. W. Lewis), 892
Changes in the Inclination of Satellite Orbits to the Equator (R. H. Merson, D. G. King-Hele and R. N. A. Plimmer), 239
Changes in Lymphocytes during Antibody Production (K. W. Keohane and W. K. Metcalf), 195
Changes in Œstrogen Titre in Stored Urine (Y. A. Leon, R. D. Bulbrook and F. C. Greenwood), 189
Changes in the Osteoblastic and Mitochondrial Population of Ageing Periosteum (Dr. E. A. Tonna and Dr. N. Pillsbury), 337
Changes in *p*H and Temperature in Poultry Breast Muscles at Slaughter (F. E. Peters and J. W. Dodge), 687
Changes in the Secretion of 20*α*-Hydroxy-pregn-4-en-3-one by the Adrenal Gland of Young Calves (Dr. W. E. Balfour, Dr. R. S. Comline and R. V. Short), 467
Changes produced in Serum Lipoproteins of Dogs by Cellulose containing Methyl Groups (Margaret M. Fröhlich, V. Balázs, K. Kovács and A. Benkö), 1119
Changes in Serum Transaminase Activity following Myocardial Damage due to Lymphatic Congestion (M. Földi, Dr. P. Braun, Dr. M. Papp and Dr. I. Horváth), 1333
Changes in Specificity and Electrophoretic Mobility of the Precipitating Antibodies present in the Serum of Cattle recovering from Foot-and-Mouth Disease (F. Brown and J. H. Graves), 1688
Changes in Transition Probability due to the Interaction of Rotation and Vibration in Diatomic Band Spectra (R. C. M. Learner and Dr. A. G. Gaydon), 242
Changes (Chemical), in Human Bronchial Epithelium and their relation to Bronchial Cancer (J. Chayen, Prof. G. J. Cunningham and D. P. Winstanley), 1743
Changes (Functional), in the Vacuole-containing Bodies of the Gastric Parietal Cell (A. D. Hally), 408
Changes (Histochemical), in the Epiphyseal Cartilage during Rickets (Prof. J. T. Irving), 1734
Changes (Seasonal), in the Brain-case of the Common Shrew (*Sorex araneus* L.), (Peter Crowcroft and Jean M. Ingles), 907
Changes (Structural Chromosome) : Induction of, by Visible Light (Dr. B. A. Kihlman), 976
Changing Industry (British Institute of Management Conference on), 655
Changing Vision (Man's), of the Universe : The Sleepwalkers—a History of (Arthur Koestler), *review* by Dr. A. R. Hall, 1419
Chapelcross Nuclear Power Station, 649 ; (J. C. C. Stewart), 1361
Chapman, D., and others : Liquid/Solid Content of Fats, 44
Chapman, Prof. S. : Space Research (The Aurora), 362
Chapman, Victor, and others : Genetic Control of Chromosome Pairing in Intergeneric Hybrids with Wheat, 1241
Chappell, Dr. J. B., and Greville, Dr. G. D.: Inhibition of Electron Transport and the Swelling of Isolated Mitochondria, 1525
  Effects of 2:4-Dinitrophenol and other Agents on the Swelling of Isolated Mitochondria, 1737
Character (Possible), for the Identification of Sharks : Red Muscle as a (Olaf R. Braekkan), 556
Characteristic Wealden Ferns in the Jabalpur Series : Occurrence of Two (Dr. M. N. Bose and Sukh Dev), 130
Characteristic (Gram), of Cells : A Correlation between Iodine Permeability and the (Prof. J. W. Bartholomew, Thomas Cromwell and Harold Finkelstein), 123
Characteristics of the Antarctic Ice-Sheet (Royal Astronomical Society and the British Glaciological Society Geophysical Discussion on), 1575
Characteristics of the Bartonellas, *review* by Dr. A. Lwoff, 207
Characteristics (Phase), of Radio Signals received via the Ionosphere (D. W. Morris and C. J. Hughes), 310
Characterization of Molecular Weight Distributions by a Viscometric Method (Dr. P. F. Onyon), 1670
Characterization of a Second Yellow Compound from *Drosophila melanogaster* (Dr. H. S. Forrest, Dolph Hatfield and Dr. C. Van Baalen), 1269
Characters (Acquired) : Canalization of Development and Genetic Assimilation of (Prof. C. H. Waddington), 1654
Characters (Production), in the Fowl : Effect of Controlled Lighting on (J. C. Bowman and J. D. H. Archibald), 1138
Charge (Tubular), of Explosive : Advance Detonation in a (Dr. D. W. Woodhead), 1756
Charges (Surface), produced on Insulators by Short- and Long-time Ionization (Dr. Stanley I. Renolds), 671
Charnock, Dr. H. : Turbidity Currents, 657
Chars (Low-Temperature) : Smoke Emission of (W. N. Adams, A. F. Gaines, D. H. Gregory and G. J. Pitt), 33 ; (Prof. Morris W. Travers), 1321
Charvát, Prof. J., and others : Fractionation of Brain Extracts for Acid Phosphatase-elevating Activity, 473
Chaston, I. R. M. : Awarded the William Frecheville Student's Prize of the Institution of Mining and Metallurgy, 1499
Chatterjee, Prof. S. P. : Awarded the Murchison Grant of the Royal Geographical Society, 292
Chayen, J., and others : Chemical Changes in Human Bronchial Epithelium and their relation to Bronchial Cancer, 1743
Chelate Compounds (Metal), of *β*-Diketones : Metal–Oxygen Stretching Frequencies in the (Kazuo Nakamoto, Paul J. McCarthy and Arthur E. Martell), 459
Chelating Agents : Reaction of some Silicates with (Dr. D. A. Sutton, M. D. Middleton and R. A. F. Body), 99, *erratum*, 1719
Chelometric Titrations (Semi-Micro) : A New Sensitive Indicator for (Prof. Robert H. Maier), 461
Chelsea College of Science and Technology : New Building (N. M. H. Lightfoot), 1722
Chemical Analysis : Magnetometric Titration—a New Method of (Dr. M. S. Blackie and Dr. V. Gold), 1804
Chemical Aspects of the Production and Use of Grass (Dublin and District Section and the Agriculture Group of the Society of Chemical Industry Symposium on), 1783

- Chemical Basis for the Classification of Glume Colour in Nigerian Cultivated Sorghums (W. R. Stanton, T. B. Miller and D. L. Curtis), 807
- Chemical Carcinogen : Response of Newly Born Mice to a (Giuseppe Pietra, Kathryne Spencer and Prof. Philippe Shubik), 1689
- Chemical Changes in Human Bronchial Epithelium and their relation to Bronchial Cancer (J. Chayen, Prof. G. J. Cunningham and D. P. Winstanley), 1743
- Chemical Composition of Tektites (Dr. Brian Mason), 254 ; (Prof. Harold C. Urey), 1114
- Chemical Destruction of Mature Perithecia of *Mycosphaerella pinodes* (M. V. Carter), 162, *erratum*, 438
- Chemical Engineering at Cambridge, 719
- Chemical Engineering : Fluid Systems in, *review* by Prof. J. M. Coulson, 492
- Chemical Engineering Practice (edited by Herbert W. Cremer and Trefor Davies), Vol. 5, Fluid Systems I, *review* by Prof. J. M. Coulson, 492
- Chemical Engineers, Institution of, and others : Joint Symposium on Instrumentation and Computation in Process Development and Plant Design, 652
- Chemical Excitation of Spinal Neurones (Dr. D. R. Curtis, J. W. Phillis and Dr. J. C. Watkins), 611
- Chemical Exploration of the Cell : Physical and, *review* by Dr. R. Barer, 1355
- Chemical Industry, Society of : Society Medal for 1959 awarded to Dr. Francis H. Carr, 722
  - Appointment of Dr. E. J. Solvay as president, 1024
- Chemical Industry, Society of (Dublin and District Section and the Agriculture Group) : Symposium on Chemical Aspects of the Production and Use of Grass, 1783
- Chemical Institute, Royal Australian : H. G. Smith Memorial Medal awarded to Prof. S. J. Angyal, 794
- Chemical Institute of Canada (National Research Council of Canada, in co-operation with the) : Ninth Canadian High Polymer Forum, 1643
- Chemical Laboratory (National), Teddington : Appointment of Dr. J. S. Anderson as director, 1719
- Chemical Notation : A Proposed International (prepared by the Commission on Codification, Ciphering and Punched Card Techniques of the International Union of Pure and Applied Chemistry), tentative version subject to revision, *review* by Dr. E. H. Rodd, 960
- Chemical Radiation Damage : Thermal Annealing of (Dr. A. G. Maddock and S. R. Mohanty), 86
- Chemical Reactions : Electronic Theory and (R. W. Stott), fourth edition, *review* by Dr. R. I. Reed, 968
- Chemical Research Laboratories of the Commonwealth Scientific and Industrial Research Organization, Australia, 228
- Chemical Society : Corday—Morgan Medal and Prize for 1957 awarded to Prof. G. W. Kenner, 792
  - To publish a cover-to-cover translation of the Russian *Zhurnal neorganicheskoi Khimii*, 1092
  - Symposium on Fluorine Chemistry, 1304
  - Presidential Address (Prof. H. J. Emeléus), 1785
- Chemical Society (sponsored by the International Union of Pure and Applied Chemistry) : Fourth International Conference on Co-ordination Chemistry, 1784
- Chemical Society, American : Monograph Series No. 138, Aliphatic Fluorine Compounds (A. M. Lovelace, Douglas A. Rausch and William Postelnek), *review* by Prof. R. N. Haszeldine, 139
  - 1958 Pittsburgh Award of the Pittsburgh Section awarded to Dr. Max A. Lauffer, 224
  - 1959 Dexter Award awarded to Prof. John Read, 1304
- Chemical Synthesis of Hexose and Hexosamine Sulphates (Dr. A. G. Lloyd), 109
- Chemical and Biological Examination (Bacteriological,), of the London Waters for the Years 1955-56 : Thirty-seventh Report on the Results of the (E. Windle Taylor), 798
- Chemically Induced Breast Tumours in Mice of the *IF* Strain : Local Inhibition by Lactation of (June Marchant), 629
- Chemically Induced Carcinoma of the Uterine Cervix : Virus-like Particles in (Dr. M. Thiery, Dr. M. De Groodt, Prof. F. De Rom, Prof. M. Sebruyns and Dr. A. Lagasse), 694
- Chemicals on Insects : Methods of Testing (edited by Harold H. Shepard), Vol. 1, *review* by Dr. W. A. L. David, 352
- Chemicals on Plants : Separation of Specific and Non-Specific Effects of (Prof. T. J. Muzik and J. M. Lawrence), 482
- Chemicals (Toxic), released from a Low-flying Aircraft : Drift of (D. Yeo, N. B. Akesson and H. H. Coutts), 131
- Chemicals and Insects, *review* by Dr. W. A. L. David, 352
- Chemicals, Oil and Gas from Coal (Ministry of Power to set up a Committee on), 1162
- Chemist of the Brain : Thudichum—(Prof. David L. Drabkin), *review* by H. W. Kosterlitz, 568
- Chemistry at Edinburgh, 151
- Chemistry in relation to Medicine at Edinburgh, 1567
- Chemistry in Schools, *review* by Prof. M. J. S. Dewar, 566
- Chemistry, Royal Institute of : Symposium on Separation Processes in Analytical Chemistry, 934
  - Election of Officers, 1234
- Chemistry, Royal Institute of (London Section), and others : Debate on the motion 'That the Education of our Future Rulers should be primarily in the Sciences rather than in the Humanities,' 510, 1235
- Chemistry : Co-ordination (Chemical Society, sponsored by the International Union of Pure and Applied Chemistry, Fourth International Conference on), 1784
  - The Father of, *review* by Dr. R. E. W. Maddison, 850
  - Fluorine (Chemical Society Symposium on), 1304
  - Low Temperature Physics and—Proceedings of the Fifth International Conference on Low Temperature Physics and Chemistry, Madison, 1957 (edited by Joseph R. Dillinger), *review* by Dr. K. Mendelssohn, 1150
  - Organic Fluorine, *review* by Prof. R. N. Haszeldine, 139
  - Polymer, *review* by Prof. C. E. H. Bawn, 637
  - Radiation (Bradford Chemical Society, the Department of Chemical Technology of the Bradford Institute of Technology and the Yorkshire Council for Further Education Symposium on), 18
  - Ramsay Memorial Fellowships for Advanced Students of, 367
  - Seventh Latin American Congress of (Mexico), 294
  - The Teaching of (N. F. Newbury), second edition, *review* by Prof. M. J. S. Dewar, 566
- Chemistry of Condensed Tannins (Plant Phenolics Group Discussion on), 1168
- Chemistry of Natural and Synthetic Rubbers (Prof. Harry L. Fisher), *review* by Dr. W. J. S. Naunton, 779
- Chemistry of Propellants (Advisory Group for Aeronautical Research and Development of NATO Meeting on), 1094
- Chemistry of the Rare Radioelements—Polonium–Actinium (Dr. K. W. Bagnall), *review* by G. R. Hall, 962
- Chemistry of the Steroids (Prof. Charles W. Shoppee), *review* by Dr. E. Stedman, 636
- Chemistry of Tobacco Smoke : Bibliography on the, 1434
- Chemistry (Analytical) : Separation Processes in (Royal Institute of Chemistry Symposium on), 934
- Chemistry (Analytical), Society for : Election of Officers, 1024
- Chemistry (Carbohydrate) : Topics in, *review* by Prof. M. Stacey, 1219
- Chemistry (Clinical) : Advances in (edited by Dr. Harry Sobotka and Dr. C. P. Stewart), Vol. 1, *review* by Prof. J. N. Davidson, 5
- Chemistry (Detergent) : Some Alkyl-Aryl Sodium Sulphonates as Standard Substances in (E. Q. Laws and W. Hancock), 1473
- Chemistry (Industrial), Salters' Institute of : Appointment of Prof. A. R. J. P. Ubbelohde as director, 1094
- *Chemistry (Medicinal and Pharmaceutical), Journal of*, Vol. 1, No. 1, 1304
- Chemistry (Organic), at Birmingham, 791
- Chemistry (Organic), at Perth, Australia, 578
- Chemistry (Organic) : Electronic Theories of (John William Baker), *review* by Dr. R. I. Reed, 777
  - An Introduction to Electronic Theories of (G. I. Brown), *review* by Dr. R. I. Reed, 279
  - Names and Ciphers in, *review* by Dr. E. H. Rodd, 960
  - Nomenclature of, 1957 (International Union of Pure and Applied Chemistry), *review* by Dr. E. H. Rodd, 960
  - Recent Progress in (International Symposium on, Mexico), 294
  - Theoretical Principles of (Prof. Walter Hückel), Vol. 2, translated from the corrected seventh German edition by Prof. F. H. Rathmann, *review* by Dr. P. B. D. de la Mare, 852
- Chemistry (Physical), of High Polymers (Dr. Maurice L. Huggins), *review* by Prof. C. E. H. Bawn, 637
- Chemistry (Protein) : Advances in (edited by C. B. Anfinsen, Jr., M. L. Anson, Kenneth Bailey and John T. Edsall), Vol. 12, *review* by Dr. M. F. Perutz, 1290
  - More, *review* by Dr. M. F. Perutz, 1290
  - Recent Advances in (Department of Chemistry, Biology and Geology of the Kingston Technical College Postgraduate Lecture Course on), 86
- Chemistry (Pure and Applied) : Seventeenth International Congress of, 1368
- Chemistry (Pure and Applied), International Union of : Formation of a Special Group under the auspices of the Analytical Chemistry Section, to make recommendations for a standard terminology in Gas Chromatography, 722
  - Nomenclature of Organic Chemistry, 1957, *review* by Dr. E. H. Rodd, 960
  - A Proposed International Chemical Notation (prepared by the Commission on Codification, Ciphering and Punched Card Techniques), tentative version subject to revision, *review* by Dr. E. H. Rodd, 960
- Chemistry (Pure and Applied), International Union of (Commission on Geochemistry) : Symposium on Geochemistry, 1719
- Chemistry (Pure and Applied), International Union of (organized by the Chemical Society and sponsored by the) : Fourth International Conference on Co-ordination Chemistry, 1784
- Chemistry (Quantum) : Chemistry and (Quantum Chemistry Group, Uppsala, Discussion on), 158
- Chemistry (Seventeenth-Century) : Robert Boyle and (Prof. Marie Boas), *review* by Dr. R. E. W. Maddison, 850
- Chemistry (Structural), of Promethium (M. Bruno and Prof. U. Croatto), 601
- Chemistry and Quantum Chemistry (Quantum Chemistry Group, Uppsala, Discussion on), 158
- Chemists (Cosmetic), Society of : British Congress of Cosmetic Science, 934
- Chemists (Cosmetic) : International Federation of Societies of (Formation of an), 1366
- Chemists (European), American Society of : Neuberg Medal awarded to Dr. H. Albert Barker, 1304
- Chemostat : Bacterial Population Studies in the, *review* by Dr. A. C. R. Dean, 424
  - The Dynamics of Bacterial Populations maintained in the (Hermann Moser), *review* by Dr. A. C. R. Dean, 424
- Chemotherapy of Parasitic Diseases (Parasitology Group of the Institute of Biology Discussion on), 1029
- Chemotherapy (The New), in Mental Illness (edited by Dr. Hirsch L. Gordon), *review* by Dr. Marthe Vogt, 1007
- Cheng, C. H., and others : Low-temperature Specific Heats of Body-centred Cubic Chromium–Iron and Chromium–Manganese Alloys, 315
- Cheong, L., and others : Incorporation of 5-Iodouracil labelled with Iodine-131 into the Deoxyribonucleic Acid of Human Leukaemic Leucocytes following *in vivo* Administration of 5-Iododeoxyuridine labelled with Iodine-131, 1686
- Cherry, Prof. Colin : Economics of Telecommunication, *review*, 778
  - Stereophonic Sound Recording, Reproduction and Broadcasting, 1720
- Chesbro, William R., and Hedrick, Prof. Leslie R. : Role of Lysine in catalysing Ester Hydrolysis, 994
- Chessin, Prof. Meyer (Taylor, John J., and) : Photochemical Reduction of Blue Tetrazolium by Isolated Chloroplasts, 626
- Chester, G. V.: Problems of Collective Motion in Physics (Liquid Helium and Superconductivity), 866
- Chester, V. E. : Endogenous Metabolism of Freshly Harvested Cells of a Brewer's Yeast, 902
- Chesters, Dr. Kathleen: Palaeoecology (Tertiary Floras of the Coastal Parts of Kent, Sussex, Hampshire, Dorset and Devon), 1370
- Chichester, Prof. C. O., and others: Effects of Starvation and Diphenylamine on Carotenoids in *Phycomyces*, 188
- Chick (Growing) : Relative Rates of Liver Storage of Pure α-, β-, γ- and δ-Tocopherols in the (T. W. Griffiths), 1061
- Chick Embryo : Oxidative Phosphorylation in the (Prof. Wiktor W. Nowinski and William C. Mahaffey), 45

Chick Embryos : Sodium, Potassium, Calcium and Chloride Ion Contents and Protein Fractions in the Fluids of (Dr. Aleksandra Smoczkiewiczowa), 1260
Chick Liver : Vitamin B_{12} and Biosynthesis in (Vitamin B_{12} and Protein Biosynthesis), (Dr. M. J. Fraser and Dr. E. S. Holdsworth), 519
Chicken Embryos : Effect of Amniotic Fluid on Inhibition of Growth by Cortisone in (Dr. P. de Franciscis and Prof. W. Landauer), 617
Chicken Lumi- and Meta-Iodopsin (Action of Light on Visual Pigments), (Dr. Ruth Hubbard and Dr. Allen Kropf), 448
Child, H. C. : Awarded the Williams Prize for 1958 of the Iron and Steel Institute, 930
Child : Television and the (Dr. Hilde T. Himmelweit, A. N. Oppenheim and Pamela Vince), *review*, 780
Child (Pyridoxine-dependent) : Effects of Pyridoxine Withdrawal on Cerebral Circulation and Metabolism in a (Dr. Louis Sokoloff, Dr. Niels A. Lassen, Dr. Guy M. KcKhann, Dr. Donald B. Tower and Dr. Wayne Albers), 751
Children (Sixth-form) : Lectures for (Royal Institution), 294
Childs, Prof. John L. : Education in the Age of Science, 1436
Chilean Coast : Relationship between the Hake Fishery and a Southerly Sub-surface Return Flow below the Peru Current off the (Dr. Wilhelm Brandhorst), 1832
Chilton, D. : Inertial Navigation, 64
Chimera (Rat–Mouse) : Life-Span of Rat and Mouse Erythrocytes in the (Dr. Joan W. Goodman and Dr. L. H. Smith), 1833
Chimie : Fifth International Salon de la, 1434
Chimneys (Power Station) : Pollution from, 85
Chinese Rocks : Some Palaeomagnetic Investigations on (Dr. Chang Wen-you and Dr. A. E. M. Nairn), 254, 652
Chinese Scientific Literature (Lending Library Unit of the Department of Scientific and Industrial Research collection of), 932
Chirnside, R. N. : Elected president of the Society of Analytical Chemistry, 1024
Chisholm, A. W. J. : Appointed to the Board of the College of Technologists, 1500
Chitinase from *Streptomyces* sp. : Effect of Lytic Enzyme from *Bacillus circulans* and, on *Aspergillus oryzea* (Koki Horikoshi and Dr. Shigeji Iida), 186
Chittum, J. F. : Feedback Theory of Hydrogen Overvoltage, 589
Chivers, H. J. A., and Wells, H. W. : A New Ionospheric Phenomenon, 1178
Chloral Hydrate : Effect of, on Growth of Hair (Prof. J. Randolph Murray), 984
Chloramphenicol : Reduction in the Lethal Effects of Radiations on *Escherichia coli B* by Treatment with (Dr. N. E. Gillies and Tikvah Alper), 237
Chloramphenicol and the Survival of Airborne Bacteria (S. J. Webb), 1072
Chlorella : An Effect of Yeast Extract on the Growth of (P. J. Casselton), 1404
Chlorella vulgaris : Effect of Heavy Water on the Growth of (Janet R. Walker and P. J. Syrett), 1193
Chloride (Cobalt)–Water–Acetone : Existence of Two Liquid Phases in the System (Dr. J. N. Murrell, Dr. L. I. Katzin and B. L. Davies), 459
Chloride (Isosmotic Potassium) : Excitation of the Squid Axon Membrane in (Dr. John W. Moore), 265
Chloride (Neotetrazolium) : Reduction of, by Vitamin K_3 (T. F. Slater), 50
Chloride (Polyvinyl) : Enhancement of Radiation-induced Cross-linking of (Dr. S. H. Pinner), 1108
Chloride (Radioactive Ferric) : Effect of Dietary Phytate on Faecal Absorption of (Dr. Henry Foy, Athena Kondi and W. H. Austin), 691
Chloride (Sodium) : Adaptation of Marine Bacteria to Growth in Media lacking (Prof. D. B. Pratt and G. Waddell), 1208
Chloride (Sodium) Surfaces : Slip Sources on (Z. Morlin), 1319
Chloride Ion Contents and Protein Fractions in the Fluids of Chick Embryos : Sodium, Potassium, Calcium and (Dr. Aleksandra Smoczkiewiczowa), 1260
'Chloride-Secretory' Cells in the Gills of Teleosts (Gwyneth Parry, and F. G. T. Holliday and J. H. S. Blaxter), 1248
Chlorination of Proteins as a Method of Increasing their Opacity in the Electron Microscope (Dr. M. M. Coombs and Prof. J. F. Danielli), 1257
Chlorine : A Spectrophotometric Method for the Determination of (Zd. Spurny), 1390
Chlorins : Detection of Hydroxyl Groups in Porphyrins and (J. Barrett), 1185
Chlorophyll *in vivo* and *in vitro* : Isomerization of Poly-*cis*-carotenes by (Dr. H. Claes and T. O. M. Nakayama), 1053
Chlorophyll Formation in Albino Citrus Seedlings : Inducing (Dr. Faisal A. Minessy), 553
Chlorophyll *a* in some Corals and Marine Plants (Dr. Paul R. Burkholder, Lillian M. Burkholder and Juan A. Rivero), 1338
Chlorophyll *a* under Ultra-Violet Irradiation : Reduction of Menadione in Hexane by (Rudolph J. Marcus and Lloyd K. Moss), 990
Chlorophyll *b* : Absoprtion Spectrum and Decay Kinetics of the Metastable State of (Prof. Stig Claesson, Lars Lindqvist and Bertil Holmström), 661
Chloroplasts (Isolated) : Photochemical Reduction of Blue Tetrazolium by (John J. Taylor and Prof. Meyer Chessin), 626
Chlorothiazid in Diabetes Insipidus (Dr. J. D. Crawford and Dr. G. C. Kennedy), 891, 1368
Chlorpheniramine : Resolution of, and the Pharmacological Properties of its Isomers (R. T. Brittain, Dr. P. F. D'Arcy and Dr. J. H. Hunt), 734
Chlorpromazine : Free Radicals from (Dr. I. Gordon Fels and Marty Kaufman), 1392
  Role of Liver in Metabolism of (Dr. R. L. Young, J. J. Ross, jun., and Dr. A. R. Maass), 1396
Chmielowski, J., and Isaac, Peter C. G. : Gas–Chromatographic Observation of the Reduction of Carbon Dioxide to Methane during Anaerobic Digestion, 1120
Cholesterol-4-^{14}C : Persistence of, in the Central Nervous System (Dr. A. N. Davison and Martha Wajda), 1606
Cholesterol-level (Serum), of Rats : Influence of Dietary Cod-liver Oil and some Fractions of Cod-liver Oil on (A. P. de Groot and S. A. Reed), 1191
Choline and Inositol : Antagonism of (Dr. B. W. Agranoff and M. R. Spivey Fox), 1259
Cholinesterase of the Electric Eel : Stability of (J. F. Scaife), 541
Cholinesterase Types (Human Serum) : Differential Response of, to an Inhibitor in Potato (Dr. H. Harris and Mary Whittaker), 1808
Chondritic Meteorites : Natural Magnetic Moments of Two (Dr. F. D. Stacey and Dr. J. F. Lovering), 529
Chou Moellier (*Brassica oleracea* var.) : A Germination Inhibitor and Root-Growth Retarder in (A. G. Campbell), 1263
Choudhury, S. S., and others : Alicyclicity and Smoke Emission of Coal, 1613
Chown, Dr. Bruce, and others : A Further Example of the Kell Blood Group Phenotype K–, k–, Kp(a–b–), 1586
Christensen, Dr. L. Korsgaard : Thyroxine-releasing Effect of Salicylate and of 2,4-Dinitrophenol, 1189
Christian Ireland : Early (Máire and Liam de Paor), *review* by Joseph Raftery, 1704
Christie, M. : Parasitology (Parasitic Diseases of Domestic Animals), 1507
Christopherson, Prof. D. G. : On Being a Technologist, 1780
Chromaffin Cells : A New Type of, probably storing Dopamine (Bengt Falck, Prof. Nils-Åke Hillarp and Alf Torp), 267
Chromatograms (Column) : Adaptation of a Photometer for the Direct Recording of (Prof. M. Verzele), 604
Chromatograms (Paper) : Detection of Meprobamate on (H. S. Bedson and T. H. Farmer), 43
  Quantitative Estimation of Purines by the Visual Scanning of Photographs of (B. M. Johnstone and G. P. Briner), 681
Chromatograms (Salting-out Paper), of Antibiotics : New Types of (Dr. Joseph Úri), 1188
Chromatograph : Circular Gas (Dr. Roger S. Porter and Dr. Julian F. Johnson), 391
Chromatographic Analysis for Ricinine (Trevor Robinson and Elvin Fowell), 833
Chromatographic Behaviour of Human Albumin labelled with Iodine-131 (Dr. S. Cohen), 393
Chromatographic Method (A Two-Dimensional Paper), combining Ion-Exchange and Partition Techniques (C. S. Knight), 165
Chromatographic Patterns of Deoxyribonucleic Acid from various Tissues : Differences in (Nokubo Kondo and Syozo Osawa), 1602
Chromatographic Technique for Studying the Mechanism of Surface Catalysis (Kenzi Tamaru), 319
Chromatography : Detection and Estimation of Benzenoid Compounds by (P. Moss and A. J. Thomas), 1611
  Gas (Formation of a Special Group under the auspices of the Analytical Chemistry Section of the International Union of Pure and Applied Chemistry, to make recommendations for a standard terminology in), 722
Chromatography (Gas) : Analysis by, of a 'Pure' Sample with an 'Impure' Carrier (V. Willis), 1754
  Direct Examination of the Degradation of High Polymers by (Dr. R. S. Lehrle and Prof. J. C. Robb), 1671
  Effect of the Carrier Gas on the Sensitivity of a Thermal-conductivity Detector in (L. J. Schmauch and R. A. Dinerstein), 673 ; (Dr. N. H. Ray), 674
  Effect of the Carrier Gas on the Sensitivity of Thermal Conductivity Detectors in (Dr. B. A. Scott and Dr. A. G. Williamson), 1322
  Peak Dimensions in (C. H. Bosanquet), 252
  Separation of *m*-Xylene and *p*-Xylene by (D. H. Desty, A. Goldup and W. T. Swanton), 107
  Use of Katharometers in (Murray Eden, Arthur Karmen and John L. Stephenson), 1322
Chromatography (Gas–Liquid) : Nylon Capillary Columns for use in (R. P. W. Scott), 1753
Chromatography (Paper) : Conversion of Caffeic Acid to Esculetin during (Warren L. Butler and H. W. Siegelman), 1813
Chromatography (Rapid Quantitative Horizontal Paper), at an Elevated Temperature—Determination of Aspartic and Glutamic Acids (Henry R. Roberts and Michael G. Kolor), 460
Chromium–Iron and Chromium–Manganese Alloys : Low-temperature Specific Heats of Body-centred Cubic (C. T. Wei, C. H. Cheng and Prof. P. A. Beck), 315
Chromium–Manganese Alloys (Chromium–Iron and) : Low-temperature Specific Heats of Body-centred Cubic (C. T. Wei, C. H. Cheng and Prof. P. A. Beck), 315
Chromium Steel (12 per cent) : A New Silicide in a (H. Hughes), 1543
Chromosomal Aberrations : A New Physical Method of creating (Dr. John H. Heller and Dr. A. A. Teixeira-Pinto), 905
Chromosomal Reproduction : Effect of Colchicine on the Utilization of Thymidine labelled with Tritium during (L. F. La Cour and Dr. S. R. Pelc), 1455
Chromosome Changes (Structural) : Induction of, by Visible Light (Dr. B. A. Kihlman), 976
Chromosome Maps of *Saccharomyces* (Prof. Carl C. Lindegren, Gertrude Lindegren, Ernest E. Shult and Sharon Desborough), 800
Chromosome Number of the Potato Root Eelworm, *Heterodera rostochiensis* Wollenweber (J. Cotten), 128
Chromosome Numbers (Two New Basic), in the Musaceae (K. Shepherd), 1539
Chromosome Pairing in Intergeneric Hybrids with Wheat : Genetic Control of (Dr. Ralph Riley, Victor Chapman and Gordon Kimber), 1244
Chromosomes (Dividing) : Distribution of Newly Synthesized Deoxyribonucleic Acid in (Philip S. Woods and Marie U. Schairer), 303
Chromosomes (Lampbrush): Some Effects of Colchicine on (A. P. Amarose), 975
Church, Brooks D., and Halvorson, Harlyn : Dependence of the Heat Resistance of Bacterial Endospores on their Dipicolinic Acid Content, 124
Churchill College, Cambridge : Sir John Cockcroft to become the first Master, 294
  Recognition as an approved foundation of the University of Cambridge, 349
Chymotrypsin : Asymmetric Hydrolysis of Diethyl Acetamidomalonate by (Prof. Saul G. Cohen and Lucille Altschul), 1678
Ciampi, Elgin (Ray, Carleton, and) : The Underwater Guide to Marine Life, *review* by Dr. D. P. Wilson, 852
Ciba Fellowship Trust : Award of Fellowships for 1959-1960, 1161

Ciba Foundation : Symposium on the Scope of Physical Anthropology and its Place in Academic Studies (edited by D. F. Roberts and J. S. Weiner), *review* by Dr. Kenneth Little, 70
  Colloquia on Ageing, Vol. 4, Water and Electrolyte Metabolism in relation to Age and Sex (edited by G. E. W. Wolstenholme and Maeve O'Connor), *review* by Prof. P. L. Krohn, 777
  Symposium on the Neurological Basis of Behaviour (edited by G. E. W. Wolstenholme and Cecilia M. O'Connor), (in commemoration of Sir Charles Sherrington, 1857-1952), *review* by Dr. P. B. Bradley, 954
  Report for 1958, 1717
Ciliary Activity by Negative Air Ions : An Enzymatic Basis for the Acceleration of (Prof. A. P. Krueger and Richard F. Smith), 1332
Ciphers in Organic Chemistry : Names and, *review* by Dr. E. H. Rodd, 960
Circuits (Printed) : The Technology of (Dr. Paul Eisler), *review* by J. C. Cluley, 1487
Circular Gas Chromatograph (Dr. Roger S. Porter and Dr. Julian F. Johnson), 391
Circulating Cells of Infectious Mononucleosis : Incorporation of Thymidine labelled with Tritium by (Dr. F. Gavosto, A. Pileri and G. Maraini), 1691
Circulation (Cerebral), and Metabolism in a Pyridoxine-dependent Child : Effects of Pyridoxine Withdrawal on (Dr. Louis Sokoloff, Dr. Niels A. Lassen, Dr. Guy M. McKhann, Dr. Donald B. Tower and Dr. Wayne Albers), 751
Circulation (Water), in the Black Sea : Microbiology and (A. E. Kriss), 437
Circulation (Water), in Oceans (V. G. Bogorov and E. M. Kreps), 437
Circulus Willisii of Atherosclerotic Individuals : Composition of Lipids isolated from the Aorta, Coronary Arteries and (Prof. C. J. F. Böttcher, F. P. Woodford, C. Ch. Ter Haar Romeny, E. Boelsma and C. M. Van Gent), 47
Cis-trans Isomerism of Thioindigo Dyes in the Solid State (Dr. G. S. Egerton), 389
Citron, K. M., and others : Immunological Aspects of Allergic Disorders (Allergic Hypersensitivity in Man to *Aspergillus fumigatus*), 297
Citrus Fruit : Isolation of *l*-Quinic Acid in (Dr. S. V. Ting and Dr. E. J. Deszyck), 1404
Citrus Ovules : Morphogenetic Response of, to Growth Adjuvants in Culture (N. S. Ranga Swamy), 735
Citrus Seedlings (Albino) : Inducing Chlorophyll Formation in (Dr. Faisal A. Minessy), 553
Citterio, C. (Mascitelli-Coriandoli, E., and) : Effects of Vanadium upon Liver Coenzyme *A* in Rats, 1527
City Literary Institute, London : Science Lectures (Tools of Scientific Discovery—a Review for the Layman and Non-Specialist), 18
City and Guilds of London Institute and the Institute of Science Technology : Rationalization of examinations and qualifications for science laboratory technicians, 863
Civic Trust : Work of the, 1092
Cladocera : Carotenoid Pigment in *Spirobacillus cienkowskii* Metchnikoff, a Pathogen of (J. Green), 56
Claes, Dr. H., and Nakayama, T. O. M. : Isomerization of Poly-*cis*-carotenes by Chlorophyll *in vivo* and *in vitro*, 1053
Claesson, Prof. Stig, and others : Absorption Spectrum and Decay Kinetics of the Metastable State of Chlorophyll *b*, 661
  Action of Ultra-violet Light on Skin—Effect of the Histamine Liberator 48/80 and Methotrimeprazine, 1451
Clam : Effect of Brain Ganglioside on the Heart of the (Dr. Samuel Bogoch and Elenore S. Bogoch), 53
Clancy, M. J. (Turvey, Dr. J. R., and) : Some Methods for the Purification of Sugar Sulphates, 537
Clapeyron's Equation : Validity of, for Phase Equilibria involving Clathrates (Dr. J. H. van der Waals and Dr. J. C. Platteeuw), 462 ; (Prof. R. M. Barrer), 463
Clapham, Prof. A. R. : Elected a Fellow of the Royal Society, 860
Clark, Dr. A. M. : Mutagenic Activity of the Alkaloid Heliotrine in *Drosophila*, 731
Clark, Comdr. E. Bidder, and Clark, Dr. G. Kitson : The Art of Lecturing, enlarged edition, 1623
Clark, E. R. : Interaction between Organic Hydroxy Acids and Germanic Acid in Aqueous Solution, 536
Clark, Francis E., and others : Responses of Seedlings to Extracts of Soybean Nodules bearing Selected Strains of *Rhizobium japonicum*, 308
Clark, Dr. G. A. : Administrative Medicine, *review*, 639
Clark, Dr. G. Kitson, and Clark, Comdr. E. Bidder : The Art of Lecturing, enlarged edition, 1623
Clark, J. E. (Heath, Prof. O. V. S., and) : Metal-Chelating Properties of Plant-Growth Substances, 1167
Clark, M. E. (Clark, Dr. R. B., and) : Role of the Supra-oesophageal Ganglion during the Early Stages of Caudal Regeneration in some Errant Polychaetes, 1834
Clark, Dr. R. B., and Clark, M. E. : Role of the Supra-oesophageal Ganglion during the Early Stages of Caudal Regeneration in some Errant Polychaetes, 1834
Clark, Sir Wilfrid le Gros: Bronze bust in the new building of the Department of Human Anatomy, Oxford, 1573
Clarke, Dr. C. A. : Natural Selection in Man, 160
Clarke, R. H. : Antarctic Meteorology, 1503
Clarkson, J. K. (Deutsch, Dr. J. A., and) : Nature of the Vibrato and the Control Loop in Singing, 167
Class of Biologically Active Substances : 'Pheromones', a New Term for a (Dr. P. Karlson and Prof. M. Lüscher), 55
Class (Social), and Mental Illness (Prof. August B. Hollingsworth and Prof. Frederick C. Redlich), *review* by Dr. Clifford Allen, 354
Classical Association (London Branch), and others : Debate on the motion 'That the Education of our Future Rulers should be primarily in the Sciences rather than in the Humanities', 510, 1235
Classification of the Digenetic Trematodes, *review* by Dr. Ben Dawes, 957
Classification of Glume Colour in Nigerian Cultivated Sorghums : A Chemical Basis for the (W. R. Stanton, T. B. Miller and D. L. Curtis), 807
Classification of the Tea Plant : Nomenclature and (Dr. W. Wight), 1726
Classified Bibliography of Gerontology and Geriatrics, Supplement 1, 1949-1955 (Dr. Nathan W. Shock), *review* by Prof. P. L. Krohn, 777
Clathrates : Validity of Clapeyron's Equation for Phase Equilibria involving (Dr. J. H. van der Waals and Dr. J. C. Platteeuw), 462 ; (Prof. R. M. Barrer), 463
Clausen, Prof. Jens C. : Elected a member of the United States National Academy of Sciences, 1575
Claxton, G. : Physical and Azeotropic Data—Hydrocarbons and Sulphur Compounds boiling below 200°C., *review* by Dr. B. A. Rose, 709
Clay Minerals and Biological Fibres (X-Ray Analysis Group of the Institute of Physics Conference on), 1024
Clay Minerals and Industry (Clay Minerals Group of the Mineralogical Society Meeting on), 1024
Clay–Water Systems : Swelling of (L. A. G. Aylmore and Dr. J. P. Quirk), 1752
Clays : Latent Interparticle Forces in (R. H. G. Parry), 538
Clayton, C. G., and others : Conductivity induced by Radiation in Polycrystalline Cadmium Sulphide and Polyethylene, 1112
Clayton (James) Prize for 1958 of the Institution of Mechanical Engineers awarded jointly to William Munger Heynes and Sir F. Ewart Smith, 865
Clayton, Y. M., and others : Immunological Aspects of Allergic Disorders (Allergic Hypersensitivity in Man to *Aspergillus fumigatus*), 297
Clearance-rates (Iodine-131), as an Indication of the Blood Supply of Bone (Dr. P. G. Laing and Dr. Albert B. Ferguson, jun.), 1595
Cleavage Faces (Calcite) : Etch Pits on (Dr. H. Watts), 314; (R. C. Stanley), 1548
Cleavage Fracture (Ductile), of Molybdenum (A. A. Johnson and B. J. Shaw), 1542
Cleaver, A. V. : Hydrogen Liquefaction and Associated Techniques (Liquid Hydrogen as a Rocket Fuel), 1505
Clegg, John : The True Book about Insects, *review* by B. D. Moreton, 709
Clematis Cuttings : Effect of Boron on the Rooting of (Dr. C. J. Weiser), 559
Clemedson, Carl-Johan, and others : Bone and Radiostrontium, *review* by J. Vennart, 965
Clerk in Industry : The, *review*, 494
Clifton, Charles E. (edited by, in association with Raffel, Sidney, and Starr, Prof. Mortimer P.) : Annual Review of Microbiology, Vol. 12, *review*, 1219
Climate of New Zealand (Prof. B. J. Garnier), *review* by Prof. Gordon Manley, 421
Climatological Wind Tunnel (Dr. P. E. Weatherley and H. D. Barrs), 94
Climatology : Geographical, *review* by Prof. Gordon Manley, 421
Clinical Chemistry : Advances in (edited by Dr. Harry Sobotka and Dr. C. P. Stewart), Vol. 1, *review* by Prof. J. N. Davidson, 5
Clinical Enzymology (edited by Dr. Gustav J. Martin), *review* by Prof. F. G. Young, 1151
Clinical Haematology in Medical Practice (Dr. G. C. de Gruchy), *review* by Dr. R. Biggs, 1151
Clinical Research (Basic and), of the New Antibiotic, Kanamycin (Maxwell Finland, and 93 other authors), 1570
Clinical and Experimental Cancer Research, *review* by Dr. L. Foulds, 955
Clipping the Coat : Effect of, on the Thermoregulatory Reactions of Dairy Heifers (H. Berman and H. H. Kibler), 606
Clock' ('Internal), in *Arthrenus verbasci* (L.) (Col., Dermestidae) : Control of Diapause by an (G. M. Blake), 126
Clotting : Appearance of a Phosphorus Compound in Platelet-rich Plasma on (Dr. G. V. R. Born and Dr. M. P. Esnouf), 478
Cloud (Large Magellanic) : Planetary Nebulae in the (E. M. Lindsay), 453
Cloud Droplets : Detachment of Conidia by (Dr. R. R. Davies), 1695
Clough Memorial Research Fund of the Edinburgh Geological Society : Grants for geological research in Scotland and the north of England, 582
Cluley, J. C. : Printed Circuits, *review*, 1487
Coal : Alicyclicity and Smoke Emission of (B. K. Mazumdar, S. S. Choudhury and A. Lahiri), 1613
  The Nature of (Central Fuel Research Institute, India, Symposium on), 86, 1438
  Chemicals, Oil and Gas from (Ministry of Power to set up a Committee on), 1162
  Potentiometric Titration of, in a Non-Aqueous Medium (W. J. S. Pringle), 815
Coal Utilization Research Association, British : Open Days, 1024, 1786
Coal, Electricity and Gas Industries : Investment in the, 1650
Coales, J. F. : Education of Instrument Technologists and Control Engineers (Presidential Address to the Society of Instrument Technology), 1433
Coals : Alicyclic Structures in (S. Ergun and V. H. Tiensuu), 1668
Coast (Atlantic), of France: *Balanus tulipiformis* Ellis on the (B. S. Kisth), 341
Coast (Chilean) : Relationship between the Hake Fishery and a Southerly Sub-surface Return Flow below the Peru Current off the (Dr. Wilhelm Brandhorst), 1832
Coast (Madras) : Metacercaria (Allocreadioidea) in the Planktonic Ctenophore, *Pleurobrachia globosa* Moser 1903, from the (Mrs. Sita Anantaraman), 1407
Coat : Effect of Clipping the, on the Thermoregulatory Reactions of Dairy Heifers (H. Berman and H. H. Kibler), 606
Coat Color in Dogs : The Inheritance of (Dr. Clarence C. Little), *review* by Dr. Alex Comfort, 5
Coates, G. E., and others : Co-ordination Chemistry (Alkyl and Aryl Palladium Compounds), 1785
Coatings (Resin-bonded), of Polytetrafluoroethylene (Acheson Colloid, Ltd.), 1501
Coats, D. A., and others : Lithium Retention in Ascites Tumour Mice, 1128
Coats (Peter) Scholarship (Textile Institute), 933
Cobalt in Dietary Necrotic Liver Degeneration : Ineffectiveness of Molybdenum, Osmium and (Dr. Klaus Schwarz, Edward E. Roginski and Calvin M. Foltz), 472
Cobalt Chloride–Water–Acetone : Existence of Two Liquid Phases in the System (Dr. J. N. Murrell, Dr. L. I. Katzin and B. L. Davies), 459
Cockburn, Dr. Alexander M. : *Obituary* by Prof. F. H. Stewart, 1017
Cockcroft, Sir John : Honorary degree of doctor of technical science conferred on, by the Technical University of Delft, 154
  To become the first Master of Churchill College, Cambridge, 294
Cockrem, F. : Selection for Relationships Opposite to those predicted by the Genetic Correlation between Two Traits in the House Mouse (*Mus musculus*), 342
  Effect of a Sympathomimetic Agent (Methoxamine Hydrochloride) on Growth of Hair in the House Mouse (*Mus musculus*), 614
Cod : The Bear Island—Migrations and Movements (G. C. Trout), 1100

Cod-liver Oil (Dietary), and some Fractions of Cod-liver Oil : Influence of, on Serum Cholesterol-level of Rats (A. P. de Groot and S. A. Reed), 1191
Cod Myosin : Aggregation of, during Frozen Storage (J. J. Connell), 664
Coe, E. L., and others : Energy Compensation in the Crabtree Effect with Ehrlich Ascites Carcinoma Cells, 1471
Coed Dolgarrog Nature Reserve (Nature Conservancy), 1649
Coed Gorswen Nature Reserve (Nature Conservancy), 1650
Coefficient (Townend's First Ionization), in Pure Nitrogen (Dr. A. E. D. Heylen), 1545
Coelacanth : Anatomy of a, *review* by Dr. E. Trewavas, 566
Coelenterata (Precambrian), from Australia, Africa and England (Dr. M. F. Glaessner), 1472
Coenzyme A (Liver), in Rats : Effects of Vanadium upon (E. Mascitelli-Coriandoli and C. Citterio), 1527
Co-existence of the Embryonic (Third Normal) Haemoglobin Fraction with Erythroblastosis in the Blood of Two Full-term New-born Babies with Multiple Malformations (Prof. I. Halbrecht, Ch. Klibanski and F. Bar Ilan), 327
Coffees (Ethiopian) : Preliminary Information on the Genetics of (Dr. Alcides Carvalho), 906
Coffield, T. H., and co-workers : Co-ordination Chemistry (Carbon Monoxide Exchange Studies), 1785
Cohen of Birkenhead, Rt. Hon. Lord : Sherrington—Physiologist, Philosopher and Poet, *review* by Prof. K. J. Franklin, 209
Cohen, Dr. A. (Cohen, Dr. L., and) : Radiosensitivity as a Function of Antigenic Equivocation, 692
Cohen, Dr. Alvin J. : Origin of Libyan Desert Silica-Glass, 1548
Cohen, Dr. Alan S., and Calkins, Dr. Evan : Electron Microscopic Observations on a Fibrous Component in Amyloid of Diverse Origins, 1202
Cohen, Prof. John : Behavior and Psychological Man, *review*, 781
Cohen, Prof. John, and Hansel, C. E. M. : Preferences for Different Combinations of Chance and Skill in Gambling, 841
Cohen, Dr. L., and Cohen, Dr. A. : Radiosensitivity as a Function of Antigenic Equivocation, 692
Cohen, Dr. Melvin : The Ear under Water (Anatomy of the Statocyst of the Lobster, *Homarus americanus*), 1787
Cohen, Dr. S. : Chromatographic Behaviour of Human Albumin labelled with Iodine-131, 393
Cohen, Prof. Saul G., and Altschul, Lucille : Asymmetric Hydrolysis of Diethyl Acetaminomalonate by Chymotrypsin, 1678
Cohesive Energy Density of Polystyrene (Dr. J. H. S. Green), 818
Cohn, Dr. N. S., and Merz, Dr. T. : A Technique for the Sterile Culture of Roots, 412
Coitus (Triple), in the Mealy Bug, *Planococcus citri* (Risso), (Walter A. Nelson-Rees), 479
Coker, Prof. E. G., and Filon, Prof. L. N. G. : A Treatise on Photo-Elasticity, second edition, revised by H. T. Jessop, *review* by E. K. Frankl, 1010
Colchicine : Effect of, on the Utilization of Thymidine labelled with Tritium during Chromosomal Reproduction (L. F. La Cour and Dr. S. R. Pelc), 1455
  Inhibitory Effect of, upon the Transplantable Fibroma of the Skin in the Newt *Triturus taeniatus* (Prof. A. Stolk), 555
  Some Effects of, on Lampbrush Chromosomes (A. P. Amarose), 975
Cold Spring Harbor Symposia on Quantitative Biology : Vol. 24, Genetics and 20th Century Mendelism, 934
  Vol. 22, Population Studies—Animal Ecology and Demography, *review* by Dr. A. Milne, 1220
Cole, Eric K. : Elected an honorary member of the British Institution of Radio Engineers, 582
Cole, Prof. F. J. : *Obituary* by Prof. Chas. H. O'Donoghue, 788
Cole, Dr. H. A. : Appointed director of fisheries research in the Ministry of Agriculture, Fisheries and Food, 1567 ; work of, 1567
Cole, K. D. : Low-Energy Corpuscular Radiation at High Latitudes, 738
Coleoptile Tissues : Relationship between Auxins and Nucleic Acid Synthesis in (B. B. Biswas and S. P. Sen), 1824
Collagen : Occurrence of 'Ester-like' Linkages in (Paul M. Gallop, Prof. Sam Seifter and Edward Meilman), 1659
Collagen in the Perilemma of Insect Nerve (David S. Smith and Prof. V. B. Wigglesworth), 127
Collagen Content of Normal Connective Tissue, of Tissue surrounding a Tumour and of Growing Rat Sarcoma (Maria Grabowska), 1186
Collagen Structure : Possible Role of Water in (R. D. B. Fraser and T. P. Macrae), 179
Collard, Prof. Patrick, and Levi, Simon : A Two-stage Fermentation of Cassava, 620
Collective Motion in Physics : Problems of (Physical Society Conference on), 866
College of Technologists : Creation of the, 1500
  Appointments to the Board, 1500
College Biology Courses on Television, 649
College (The American), and the Educated Life (Dr. Douglas M. Knight), 1769
Colleges and Universities : Scientific Research and Development in—Expenditure and Manpower, 1953-54 (National Science Foundation), 1716
Collier, Prof. H. Bruce (Tsen, Dr. Cho Ching, and) : Selenite as a Relatively Weak Inhibitor of some Sulphydryl Enzymes, 1327
Collier, Dr. H. O. J. : Chemotherapy of Parasitic Diseases, 1030
  Appointed to the Board of the College of Technologists, 1500
Collier, Dr. H. O. J., and others : A New Short-Acting Thiobarbiturate, 1443, *erratum*, 1571
Colloid Goitre (Experimental), produced by Thiouracil (Dr. R. H. Follis, Jun.), 1817
Colloid Osmotic Pressure of Rheumatoid Synovial Fluid (Paave Mäkinen and Eino Kulonen), 475
Colloid Science : Electrical Double Layer in (Colloid and Biophysics Committee of the Faraday Society Discussion on), 78
Colombo Plan for Co-operative Economic Development in South and South-East Asia : Seventh Annual Report of the Consultative Committee (Seattle, 1958), 1099
Colon ('Isolated') : Enzyme Activity in the (Dr. B. F. Martin), 1464
Colonial Agricultural, Animal Health and Forestry Research, Committee for : Thirteenth Annual Report (1957-58), 703
Colonial Development and Welfare Bill : Second reading of the, 793
Colonial Economic Research Committee : Eleventh Annual Report (1957-58), 703
Colonial Fisheries Advisory Committee : Annual Report (1957-58), 703
Colonial Geology and Mineral Resources renamed *Overseas Geology and Mineral Resources* (Overseas Geological Surveys), 581
Colonial Medical Research Committee : Thirteenth Annual Report (1957-58), 703
Colonial Pesticides Research Committee : Eleventh Annual Report (1957-58), 703
Colonial Products Council : Fifth Annual Report (1957-58), 703
Colonial Research 1957-58—Reports of the Colonial Research Council ; Committee for Colonial Agricultural, Animal Health and Forestry Research ; Colonial Economic Research Committee ; Colonial Fisheries Advisory Committee ; Colonial Medical Research Committee ; Colonial Pesticides Research Committee ; Colonial Social Science Research Council ; Tsetse Fly and Trypanosomiasis Committee, Director of the Anti-Locust Research Centre ; and Research Matters not covered by the above Reports of the Specialist Advisory Bodies, 703
Colonial Research Council : Annual Report of the, 703
Colonial Road Research Committee : Third Annual Report (1957-58), 703
Colonial Social Science Research Council : Fourteenth Annual Report (1957-58), 703
Color (Coat), in Dogs : The Inheritance of (Dr. Clarence C. Little), *review* by Dr. Alex Comfort, 5
Colorimetric Analysis (Noel L. Allport and Dr. J. W. Keyser), Vol. I, Determinations of Clinical and Biochemical Significance, second edition, *review* by Dr. N. R. Lawrie, 207
Colorimetry in Biochemistry, *review* by Dr. N. R. Lawrie, 207
Colour in Frogs : Serotonin and Change of (Dr. K. G. Davey), 1271
Colour (Autumn), and Leaf-fall of Deciduous Woody Plants : Effect of Gibberellic Acid on Development of (Dr. P. W. Brian, J. H. P. Petty and P. T. Richmond), 58
Colour (Glume), in Nigerian Cultivated Sorghums : A Chemical Basis for the Classification of (W. R. Stanton, T. B. Miller and D. L. Curtis), 807
Colour-blindness in Klinefelter's Syndrome (Prof. Curt Stern), 1452
Colour Centres in Silica : Synthesis of, and their Thermoluminescence (J. R. Hensler), 672, *erratum*, 1434
Colour Reaction for Thiosulphinates (John F. Carson and Francis F. Wong), 1673
Colour Vision : Mixed Pigments in (Dr. R. W. G. Hunt), 1601
Colour Vision Phenomenon of a New Class (Dr. William A. Shurcliff), 202
Colours of Dogs, *review* by Dr. Alex Comfort, 5
Colson, P. (Gillet, Prof. A., and) : The Nature of Coal (Petroleum and Anthracite from Cellulose), 1438
Colston Research Society : Observation and Interpretation—Proceedings of the Ninth Symposium held at the University of Bristol, 1957 (edited by Prof. S. Körner in collaboration with Prof. M. H. L. Pryce), *review* by Dr. E. F. Caldin, 1010
Colton, Dr. Ervin, and St. Cyr, Lewis: Solution of Iodine in Phosphorus (III) *Iso*cyanate, 1042
Colton, R., and others : Lowest Oxidation States of Technetium and Rhenium, 1755
Column Chromatograms : Adaptation of a Photometer for the Direct Recording of (Prof. M. Verzele), 604
Colvin, Dr. J. Ross : Synthesis of Cellulose in Ethanol Extracts of *Acetobacter xylinum*, 1135
Coma Cluster of Galaxies : A High-Resolution Survey of the, at 408 Mc./s. (Dr. M. I. Large, D. S. Mathewson and C. G. T. Haslam), 1663
Combinations (Antibiotic) : Application of Logarithms to the Base 2 in the Use of Exponential Dilution Series for the Study of (H. J. Oskam and A. Koelman), 840
Combinations (Different), of Chance and Skill in Gambling : Preferences for (Prof. John Cohen and C. E. M. Hansel), 841
Combinatorial Analysis : An Introduction to (John Riordan), *review* by Dr. L. S. Goddard, 970
Combining Sites of an Antibody : Effect of Hydrolysis by Papain on the (Dr. A. Nisonoff and D. L. Woernley), 1325
Combustibles et de l'Energie, Institut Français des : Gold Medals presented to Dr. D. T. A. Townend, Prof. W. H. McAdams, G. Darrieus, Prof. G. Ribaud, Dr. F. Münzinger and F. Squassi, 151
Comfort, Dr. Alex : The Colours of Dogs, *review*, 5
Comforts : Atomic, *review* by Prof. G. O. Jones, 1077
Comité Européen de Zoologie Agricole and the Agricultural University, Wageningen (under the auspices of the) : Proceedings of a Symposium on Insect and Food-plant (Wageningen, 1957), *review* by Dr. C. J. Banks, 1767
Comline, Dr. R. S., and others : Changes in the Secretion of 20α-Hydroxypregn-4-en-3-one by the Adrenal Gland of Young Calves, 467
Comments on the Job (Dr. Isabel Blain), 372
Commercial Basis : Nuclear Reactors on a, 436
Commercial Manufacture of Nuclear Fuel Elements, 1232
Common, Prof. R. H., and Mok, Chi-Ching : Phosvitin in the Serum of the Hen, 1811
Common Frog : An Albino Specimen of the (G. E. Williams), 1408
Common Sense and Nuclear Warfare (Bertrand Russell), 1351
Common Shrew (*Sorex araneus* L.) : Seasonal Changes in the Brain-case of the (Peter Crowcroft and Jean M. Ingles), 907
Commons, House of : Debate on Government Aid to Science in Britain, 156
  Debate on Safety and the Nuclear Power Industry, 292
  Second reading of the Colonial Development and Welfare Bill, 793
  Debate on the National Parks (Amendment) Bill, 917
  Second reading of the Transport (Borrowing Powers) Bill, 938
  Debate on Education, 1145
  Debate on Space Research, 1302
  Debate on Fuel and Power Policy, 1650
Commonwealth : General Trends in Science Teaching in the Universities of the (Science Masters' Association Discussion on), 1571
  Scientific Co-operation in the, 775
Commonwealth (British) : Scientific Co-operation within the (H.R.H. the Duke of Edinburgh), 425
Commonwealth (British), Association of Universities of the : Report of the Executive Council for 1957-58, 1717
  Report of the Proceedings of the 1958 Home Universities Conference, 1764
Commonwealth Advisory Committee on Defence Science—Meeting in Australia (Sir Leslie Martin), 1165

Commonwealth Bursaries Scheme : Fifth Annual Report on the (Royal Society and Nuffield Foundation), 1304
Commonwealth Fund : Award of Harkness Fellowships for 1959, 1093
Commonwealth Scientific and Industrial Research Organization (Australia) : Ninth Annual Report (1956-57), 155
  Chemical Research Laboratories, 228
  Appointment of Dr. I. W. Wark as the first director of the Chemical Research Laboratories, 228
  Appointment of Dr. A. L. G. Rees as chief of the new Division of Chemical Physics, 228
  Appointment of Dr. K. L. Sutherland as chief of the new Division of Physical Chemistry, 228
  Rural Research, 228
  Annual Report for 1957-58 of the Division of Electrotechnology, 1781
Commonwealth Students in Britain : Funds for, 793
Communication in the Modern World (Granada Lectures of the British Association for the Advancement of Science), 293
Communication Principles at the Bell Telephone Laboratories, 648
Communications and Electronics Buyers' Guide, Who's Who and Reference Book, 1958-59 edition (edited by C. C. Gee, with the assistance of D. W. Dwyer), *review* by Prof. D. G. Tucker, 354
Comparative Anatomy (Zoology and), at Dublin, 1716
Comparative Sensitivity to Radiation of Seeds from a Wild Plant grown on Uraniferous and Non-Uraniferous Soils (Dr. D. J. Mewissen, J. Damblon and Prof. Z. M. Bacq), 1449
Comparison of the Formation of the Complex, Sensitized Erythrocyte-Complement ($EAC'_{1, 4, 2}$) in Haemolytic Systems differing in their Haemolysin and Complement-fixing Activities (Dr. Harold S. Goodman), 331
Comparison of Normal Adult Human Haemoglobin with Haemoglobin I by 'Fingerprinting' (Constituents of Human Haemoglobin), (Makio Murayama and Dr. V. M. Ingram), 1798
Compensation (Energy), in the Crabtree Effect with Ehrlich Ascites Carcinoma Cells (K. H. Ibsen, E. L. Coe and Dr. R. W. McKee), 1471
Complement Fixation with Tissue Culture and Liver Antigens of Mouse Hepatitis (Dr. Theodore J. Starr and Dr. Morris Pollard), 1690
Complement-fixing Activities : Comparison of the Formation of the Complex, Sensitized Erythrocyte-Complement ($EAC'_{1, 4, 2}$) in Haemolytic Systems differing in their Haemolysin and (Dr. Harold S. Goodman), 331
Complex in the α-Globulin Fraction in Human Serum : Prealbumin as a (Dr. J. R. Tata), 877
Complex, Sensitized Erythrocyte-Complement ($EAC'_{1, 4, 2}$) : Comparison of the Formation of the, in Haemolytic Systems differing in their Haemolysin and Complement-fixing Activities (Dr. Harold S. Goodman), 331
Complex (Blue–Snow Goose) : Assortative Mating and Reciprocal Difference in the (Dr. F. G. Cooch and Dr. J. A. Beardmore), 1833
Complex (Iron-*bis*-Indigo): Model Oxygen-carrying Compounds and the (L. F. Larkworthy and Prof. R. S. Nyholm), 1377
Complexes : Copper–Cellulose (Dr. D. S. Belford, C. D. Cook, E. H. Nevard and Prof. R. D. Preston), 988
  Methanol-soluble Carbohydrate (Ernest H. Freund and Kelvin Domovs), 1526
  β-Type Interlamellar Sorption (F. Aragon, J. Cano Ruiz and Dr. D. M. C. MacEwan), 740
Complexes with *Cyclo*hexylphosphine : Tetra-co-ordination of Nickel (II)—some (Dr. Aldo Turco, Dr. Vladimiro Scatturin and Dr. Giovanni Giacometti), 601
Complexes (Ferrous and Ferric), with Pyridine 2-Aldoxime (Dr. G. I. H. Hanania and Dr. D. H. Irvine), 40
Complexes (Histidine—Cu (II)) : Multiplicity of (R. Leberman and Dr. B. R. Rabin), 746
Complexes (Pentacyanocobaltate (III)) : Polarography of (Nobufumi Maki, Junnosuke Fujita and Ryutaro Tsuchida), 458
Component (Fibrous), in Amyloid of Diverse Origins : Electron Microscopic Observations on a (Dr. Alan S. Cohen and Dr. Evan Calkins), 1202
Components of Bacterial Cytoplasm : Effect of Drugs upon (Dr. S. Dagley and J. Sykes), 1608
Components (Normal), of Guinea Pig Serum which may cause Antigens to show an Apparent Anti-complementary Effect (M. M. H. Sewell), 1062
Components (Small), in Red Cell Haemolysates : Demonstration of, by Starch-gel Electrophoresis (Dr. Phaedon Fessas and N. Mastrokalos), 1261
Composition of the Configurational Stability of Deoxyribonucleic Acids : Dependence on (Heterogeneity in Deoxyribonucleic Acids, 1), (Dr. Julius Marmur and Prof. Paul Doty), 1427
Composition of Lipids isolated from the Aorta, Coronary Arteries and Circulus Willisii of Atherosclerotic Individuals (Prof. C. J. F. Böttcher, F. P. Woodford, C. Ch. Ter Haar Romeny, E. Boelsma and C. M. Van Gent), 47
Composition (Amino-Acid), of the Proteins of Barley Leaves in relation to the Mineral Nutrition and Age of Plants (Dr. B. P. Pleshkov and Dr. L. Fowden), 1445
Composition (Cell-Wall), of *Leptotrichia* spp. (Dr. G. H. G. Davis and A. C. Baird-Parker), 1206
Composition (Chemical), of Tektites (Dr. Brian Mason), 254 ; (Prof. Harold C. Urey), 1114
Composition (Isotopic), of Boron and its Atomic Weight (W. J. Lehmann and I. Shapiro), 1324
Composition (Isotopic), of Lead from British Mineral Deposits (S. Moorbath), 595
Compound, I_2OH^- : A New Iodine (Dr. J. Sigalla), 178
Compound (An Iodine), associated with Albumin in the Plasma of Thyrotoxic Patients (Christina Cameron and K. Fletcher), 116
Compound (Phosphorus), in Platelet-rich Plasma on Clotting : Appearance of a (Dr. G. V. R. Born and Dr. M. P. Esnouf), 478
Compound (Second Yellow), from *Drosophila melanogaster* : Characterization of a (Dr. H. S. Forrest, Dolph Hatfield and Dr. C. Van Baalen), 1269
Compound Formation : Electrode Potentials and, in the Palladium–Platinum–Hydrogen System (A. W. Carson, Dr. T. B. Flanagan and Dr. F. A. Lewis), 39, 510
Compounding Ingredients for Rubber : British (compiled by Brian J. Wilson), *review* by Dr. W. J. S. Naunton, 779
Compounds : Aliphatic Fluorine (A. M. Lovelace, Douglas A. Rausch and William Postelnek), *review* by Prof. R. N. Haszeldine, 139
  Effect of Norleucine and related, on Growth of the White Rat (M. Rechcigl, jun., H. H. Williams and J. K. Loosli), 1519
  Inhibition of Sensitiveness to Nicotine of Rabbit Aorta by Reserpine, Hexamethonium, Ethyl Flavone-7-Oxyacetate and other (Dr. I. Setnikar and M. Ravasi), 898
Compounds (Benzenoid) : Detection and Estimation of, by Chromatography (P. Moss and A. J. Thomas), 1611
Compounds (C_2-) : Biosynthesis of Cell Constituents from—Formation of Malate from Glycollate by *Pseudomonas ovalis* Chester (Dr. H. L. Kornberg and A. M. Gotto), 1791 ; Metabolism of Glycine by a Pseudomonad (A. G. Callely and Dr. S. Dagley), 1793 ; Formation of Glycerate from Oxalate by *Pseudomonas oxalaticus* (OX1) grown in Oxalate (J. R. Quayle and Dr. D. B. Keech), 1794
Compounds (Crystal), of Graphite : Metallic Conduction in the (Prof. A. R. Ubbelohde, Dr. L. C. F. Blackman and J. F. Mathews), 454
Compounds (Enclathrated) : Molecular Motion of, as studied by Nuclear Magnetic Resonance (Dr. D. F. R. Gilson and Prof. C. A. McDowell), 1183
Compounds (Guanidinium), with Ninhydrin : Green Fluorescence of (Dr. Rex B. Conn, jun., and Dr. Richard B. Davis), 1053
Compounds (Metal Chelate), of β-Diketones : Metal–Oxygen Stretching Frequencies in the (Kazuo Nakamoto, Paul J. McCarthy and Arthur E. Martell), 459
Compounds (Model Oxygen-carrying), and the Iron-*bis*-Indigo Complex (L. F. Larkworthy and Prof. R. S. Nyholm), 1377
Compounds (Sulphur) : Inactivation of Organo-Mercurial Fungicides in Groundwood Pulp made from Logs stored in Salt Water and the Possible Role of (B. H. Browning, P. Russell, Dr. S. Kingsnorth and R. J. Peerless), 1346
Compounds (Sulphur), boiling below 200°C. : Physical and Azeotropic Data—Hydrocarbons and (G. Claxton), *review* by Dr. B. A. Rose, 709
Compounds (Transition Metal Co-ordination) : Explosion of (Seward E. Beacom), 38
Compounds (Trichloracetic Acid-insoluble Phosphate), in Cartilage (R. G. Whitehead and Dr. S. M. Weidmann), 876
Computation in Process Development and Plant Design : Instrumentation and (Institution of Chemical Engineers, the Society of Instrument Technology and the British Computer Society Joint Symposium on), 652
Computation and Control : Handbook of Automation, (edited by Eugene M. Grabbe, Simon Ramo and Dean E. Wooldridge), Vol. I, Control Fundamentals, *review* by P. H. Hammond, 1556
Computational Methods : Scholarships in Mathematics for Courses in Statistics and (London School of Economics and Political Science), 85
Computer : Braille Translation by, 1233
Computer and the Brain (Dr. John von Neumann), *review* by A. M. Armstrong, 350
Computer Society, British, and others : Joint Symposium on Instrumentation and Computation in Process Development and Plant Design, 652
Computer (Business) Synposium : Electronic Computer Exhibition and, 11
Computer (Electronic) Exhibition and Business Computer Symposium, 11
Computer (Electronic Digital) : The Preparation of Programs for an (Dr. Maurice V. Wilkes, Dr. David J. Wheeler and Dr. Stanley Gill), second edition, *review* by E. L. Albasiny, 969
Computers (Digital) : Automatic Programming of (Brighton Technical College Residential Working Conference on), 438, 1779
Computers (Electronic), in the Service of Business (W. L. C. Garrett), 11
Computers (Electronic Digital), and their Industrial Applications (Conference at the Birmingham College of Technology), 154
Computing Engine (The Automatic), at the National Physical Laboratory (J. H. Wilkinson and D. W. Davies), 22
Conant, Roger : A Field Guide to Reptiles and Amphibians of the United States and Canada East of the 100th Meridian, *review* by A. G. C. Grandison, 958
Concentration of Ammonium Sulphate Solutions : A Rapid Method for determining the (Dr. John A. Whitaker and Dr. Robert Hughes), 603
Concentration of Fluids containing Protein : A Simple Method for the (Dr. J. Kohn), 1055
Concentration (Salt), and Fibrinolytic Activity (Dr. Monamy Buckell and Margaret Truscott), 1268
Concentrations (Drug), in Biological Fluids : Direct Determination of, by Polarography (Dr. P. O. Kane), 1674
Concentrations (Low), of Alcohols : Effect of, on the Interfacial Tension between Water and Hydrocarbons (F. Franks and Dr. D. J. G. Ives), 316
Concept of Motivation (Dr. R. S. Peters), *review* by Prof. L. S. Hearnshaw, 567
Concept (Genetic), for the Origin of Cancer : Papers presented at the Conference on (Annals of the New York Academy of Sciences, Vol. 71), 1234
Conception of Nature : The Physicist's (Prof. Werner Heisenberg), *review* by Prof. W. H. McCrea, 1281
Concepts of Nuclear Physics, *review* by Prof. B. H. Flowers, 492
Conchie, F., and others : Glycosidases in some Farm Animals, 615
Condensation Products of Ethylenediamine with Adrenaline (Dr. Kunio Yagi and Dr. Toshiharu Nagatsu), 822
Condensed Tannins : Chemistry of (Plant Phenolics Group Discussion on), 1168
Conditioning (Recurrent), of Spinal Reflexes : Pattern of (Dr. V. J. Wilson, W. H. Talbot and F. P. J. Diecke), 824
Conductance (Electrical), and Dielectric Constant of the Interior of Erythrocytes (H. Pauly), 333
Conduction (Electric), in Semiconductors and Metals (Dr. W. Ehrenberg), *review* by Dr. P. T. Landsberg, 138
Conduction (Metallic), in the Crystal Compounds of Graphite (Prof. A. R. Ubbelohde, Dr. L. C. F. Blackman and J. F. Mathews), 454
Conduction Current (High-Field), in *n*-Hexane : Electric Strength and (A. M. Sletten), 311
Conductivity induced by Radiation in Polycrystalline Cadmium Sulphide and Polyethylene (C. G. Clayton, B. C. Haywood and Dr. J. F. Fowler), 1112
Conductivity Detectors (Thermal), in Gas Chromatography : Effect of the Carrier Gas on the Sensitivity of (Dr. B. A. Scott and Dr. A. G. Williamson), 1322

Conductors to Transistors : From, *review* by Dr. P. T. Landsberg, 138
Configuration of Poly-L-tyrosine : Optical Rotation and (A. R. Downie, Dr. A. Elliott and W. E. Hanby), 110
Configuration (Stable), of Methyl Groups in Dimethyl Ether (Katsumi Kimura and Masaji Kubo), 533
Configurational Stability of Deoxyribonucleic Acids : Dependence on Composition of the (Heterogeneity in Deoxyribonucleic Acids, I), (Dr. Julius Marmur and Prof. Paul Doty), 1427
Congenital Transmission of Toxoplasmosis through Successive Generations of Mice (Dr. J. K. A. Beverley), 1348
Congestion (Lymphatic) : Changes in Serum Transaminase Activity following Myocardial Damage due to (M. Foldi, Dr. P. Braun, Dr. M. Papp and Dr. I. Horváth), 1333
Congrès International de Prophylaxie Criminelle : First, 1783
Conidia : Detachment of, by Cloud Droplets (Dr. R. R. Davies), 1695
Conjugate (Electron-dense Antibody) : Preparation of an (Prof. S. J. Singer), 1523
Conjugate Point : 'Whistler Mode' Echoes remote from the (R. L. Dowden and G. T. Goldstone), 385
Conjugated Forms of Urobilinoid Pigments (I. L. Kahán and A. Kahán), 463
Conjugation : Glucuronide and Sulphate, *in vivo* and *in vitro* (K. H. Harper and G. Calcutt), 463
Conjugation *in vitro* (Biliyubin) : Factors affecting the Rate of (Dr. E. Talafant and J. Továrek), 111
Conn, jun., Dr. Rex B., and Davis, Dr. Richard B. : Green Fluorescence of Guanidinium Compounds with Ninhydrin, 1053
Connecticut Academy of Arts and Sciences : Memoirs, Vol. 13, The Systematics of North American *Daphnia* (Dr. John Langdon Brooks), 93
Connective Tissue : Human Muscular Dystrophy as an Aberration of the (Prof. Geoffrey H. Bourne and M. Nelly Golarz), 1741
Connective Tissue (Mammalian) : Polysaccharide Fibres in (A. J. Cruise and J. W. Jeffery), 677
Connective Tissue (Normal), of Tissue surrounding a Tumour and of Growing Rat Sarcoma : Collagen Content of (Maria Grabowska), 1186
Connell, J. J. : Aggregation of Cod Myosin during Frozen Storage, 664
Connell, Dr. P. H. : Amphetamine Psychosis, *review* by Dr. W. R. Bett, 639
Conscious Man : The Excitable Cortex in (Dr. Wilder Penfield), *review* by Dr. P. B. Bradley, 781
Consden, R., and Kohn, Dr. J. : Cellulose Acetate as a Medium for Immuno-Diffusion, 1512
Consequences of the Use of Nuclear Energy for the European Mode of Life (Council for Europe Competition for a thesis on), 509
Conservation Corps for Young Volunteers (Council for Nature), 508
Conservation (Nature), and Ecological Research, 205
Consolidated Gold Fields of South Africa, Ltd. Gold Medal for 1957-58 of the Institution of Mining and Metallurgy awarded to F. A. Williams, 1499
Consolidated Gold Fields of South Africa, Ltd. Premium for 1957-58 of the Institution of Mining and Metallurgy awarded jointly to H. H. Fraser and O. E. A. Somerset, 1499
Constant (Dielectric), of the Interior of Erythrocytes : Electrical Conductance and (H. Pauly), 333
Constituents of Human Haemoglobin—Separation of the Peptide Chains of Human Globin (Dr. V. M. Ingram), 1795 ; Comparison of Normal Adult Human Haemoglobin with Haemoglobin I by 'Fingerprinting' (Makio Murayama and Dr. V. M. Ingram), 1798 ; Formation of Normal and Doubly Abnormal Haemoglobins by Recombination of Haemoglobin I with S and C (Dr. Harvey A. Itano and Elizabeth Robinson), 1799
Constituents of Tobacco Smoke—an Annotated Bibliography (edited by H. R. Bentley and E. G. N. Berry), 1434
Constituents (Carbohydrate), of the Mycelium of *Penicillium chrysogenum* grown in Media with Different Sources of Carbon (Roshan J. Irani and Dr. K. Ganapathi), 758
Constituents (Cell), from C_2-Compounds : Biosynthesis of—Formation of Malate from Glycollate by *Pseudomonas ovalis* Chester (Dr. H. L. Kornberg and A. M. Gotto), 1791 ; Metabolism of Glycine by a Pseudomonad (A. G. Callely and Dr. S. Dagley), 1793 ; Formation of Glycerate from Oxalate by *Pseudomonas oxalaticus* OXI) grown in Oxalate (J. R. Quayle and Dr. D. B. Keech), 1794
Constitution of Lignin : Biosynthesis and (Prof. Karl Freudenberg), 1152
Consulting Scientists, Association of : Formation of, 651
  Election of Dr. J. G. Davis as chairman, 651
Consumption of Food, Intake of Water and Weight of Body in Rats : Effect of Reduction of Stimulation on (Dr. Karl Weiss and Harry M. B. Hurwitz), 344
Consumption (Oxygen), of Different Forms of Stable L *Proteus P*18 growing in Hypertonic Liquid Medium (Prof. P. Mandel, T. Terranova, M. Sensenbrenner and F. Feo), 194
Contact γ-Aluminium Oxide/Platinum : Structure and Mode of Action of the (Prof. Alfons Krause), 1615
Contamination by Extra-Terrestrial Exploration, 925
Continuous Culture : Lens Cells of the Calf in (Dr. J. van der Veen and C. F. A. Heyen), 1137
Contraction–Relaxation of Rat Tail Tendon : Effect of Cross-linking by Formaldehyde on the (Dr. H. R. Elden), 332
Contraction (Excitation–) Coupling in Heart Muscle (Prof. H. Reichel and A. Bleichert), 826
Contraction (Slow), of Smooth Muscle produced by Human Plasma (Dr. Yousry Gabr and Raga H. Aly), 897
Contraction and Relaxation in Smooth Muscles of Lamellibranch Molluscs (Dr. J. Lowy and B. M. Millman), 1730
Contrast Media (Radiographic) : Labelling of, with Iodine-131 (J. Liebster, J. Kácl and A. Babicky), 1474
Contributions to *Nature*, 15
Control : Handbook of Automation, Computation and (edited by Eugene M. Grabbe, Simon Ramo and Dean E. Wooldridge), Vol. I, Control Fundamentals, *review* by P. H. Hammond, 1556
  Smoke, 1163
Control of Bud Reactivation in *Splachnum ampullaceum* (L.) Hedw. : Interaction between Kinetin and Indoleacetic Acid in the (Prof K. E. von Maltzahn), 60
Control of Diapause by an 'Internal Clock' in *Anthrenus verbasci* (L.) (Col., Dermestidae), (G. M. Blake), 126
Control of Dust and Fumes in Industry (British Occupational Hygiene Society Conference on), 865
Control in Electrical Engineering : Measurement and (Dr. A. H. M. Arnold), 89
Control of Exhaust Fumes, 1092
Control of Leaf Senescence by Auxins (Daphne J. Osborne), 1459
Control of Superficial Scald in Stored Apples (W. Hugh Smith), 760
Control (Feedback), of Purine Biosynthesis by Purine Ribonucleotides (Dr. James B. Wyngaarden and Doris M. Ashton), 747
Control (Genetic), of Chromosome Pairing in Intergeneric Hybrids with Wheat (Dr. Ralph Riley, Victor Chapman and Gordon Kimber), 1244
Control (Genetic), of Human Haptoglobin Synthesis (Dr. A. C. Allison), 1312
Control (Genetic), of Industrial Melanism in the Lepidoptera : New Aspects of the (Dr. H. B. D. Kettlewell), 918
Control (Structural), of Polymorphism in Micas (E. W. Radoslovich), 253
Control (Temperature), of Physiological Dwarfing in Peach Seedlings (Prof. Bruce M. Pollock), 1687
Control Engineers : Education of Instrument Technologists and (J. F. Coales), 1433
Control Fundamentals, *review* by P. H. Hammond, 1556
Control and Instrumentation : Nuclear Reactor (J. H. Bowen and E. F. O. Masters), *review* by R. Vaux, 1149
Control and Instrumentation of Reactors (Harwell Reactor School Second Course on), 153
Control Loop in Singing : Nature of the Vibrato and the (Dr. J. A. Deutsch and J. K. Clarkson), 167
Control Systems : Feedback (Prof. Otto J. M. Smith), *review* by M. J. Somerville, 73
Control Theory : Basic Automatic (Prof. Gordon J. Murphy), *review* by M. J. Somerville, 211
Controlled Lighting : Effect of, on Production Characters in the Fowl (J. C. Bowman and J. D. H. Archibald), 1138
Conversion of Caffeic Acid to Esculetin during Paper Chromatography (Warren L. Butler and H. W. Siegelman), 1813
Conversion of Quinic Acid to Shikimic Acid in Roses : Evidence for the (L. H. Weinstein, C. A. Porter and H. J. Laurencot, jun.), 326
Conversion (Gene) : A Position-Effect Explanation of (Prof. J. A. Serra), 700
Conversion (Polymorphic), of Mercuric Iodide on Alumina (Prof. Harry Zeitlin and Harry Goya), 1041
Conway (River) : Feeding of the Oystercatcher (*Haematopus ostralegus*) on the Edible Mussel (*Mytilus edulis*) in the Estuary of the (R. E. Drinnan), 153
Cooch, Dr. F. G., and Beardmore, Dr. J. A. : Assortative Mating and Reciprocal Difference in the Blue–Snow Goose Complex, 1833
Cook, Dr. A. M. : The Killing of Micro-organisms, *review*, 277
Cook, C. D., and others : Copper–Cellulose Complexes, 988
Cook, Dr. J. W. : Appointed to the Board of the College of Technologists, 1500
  The Role of the Scholar in Society, 1772
Cook, Margaret J., and others : Measuring Productivity in Breeding of Small Animals, 339
Cooke, Dr. G. W. : Phosphates and Organic Substances in Nitrogen Deficiency, 513
Coombs, Dr. M. M., and Danielli, Prof. J. F. : Chlorination of Proteins as a Method of Increasing their Opacity in the Electron Microscope, 1257
Cooper, Edmund J. : Appointed general secretary of the Scientific Film Association, 18
Cooper, Susan C. (Graham, Dr. John W., and) : Biological Origin of Manganese-rich Deposits of the Sea Floor, 1050
Co-operation Administration, International : Technical Assistance Programmes of the, 1163
Co-operation (Scientific), within the British Commonwealth (H.R.H. the Duke of Edinburgh), 425
Co-operation (Scientific), in the Commonwealth, 775
Co-operation (Technical) in Africa South of the Sahara, Commission for (Food and Agriculture Organization of the United Nations and the) : Technical Meeting on Legumes in Agriculture and Human Nutrition, 439
Co-operative Economic Development in South and South-East Asia, Colombo Plan for : Seventh Annual Report of the Consultative Committee (Seattle, 1958), 1000
Co-operative Phenomena and Phase Transitions (Physical Society Conference on), 1234, 1643
5-Co-ordination of Divalent Copper (Dr. D. P. Graddon), 1610
Co-ordination (Tetra-) of Nickel (II)—some Complexes with *Cyclo*hexylphosphine (Dr. Aldo Turco, Dr. Vladimiro Scatturin and Dr. Giovanni Giacometti), 601
Co-ordination (Tetrhedral), in Ni(II), (Dr. L. I. Katzin), 1672 ; (Prof. E. C. Lingafelter), 1673
Co-ordination Chemistry (Chemical Society, sponsored by the International Union of Pure and Applied Chemistry, Fourth International Conference on), 1784
Co-ordination Compounds (Transition Metal) : Explosion of (Seward E. Beacom), 38
Cope, F. W. (Bennett, M. C., and) : Nuclear Fusion and Non-Fusion in *Theobroma cacao* L., 1540
Copepod *Elaphoidella gracilis* (Sars) : Haemoglobin and the Habitat of the Harpacticoid (J. Green), 1834
Copley, Dr. A. L., and others : Anticoagulant Action of Fibrin Surfaces on Mammalian Blood, 1683
Co-polymers (Block and Graft) : Stereo-specific Polymers and (Bradford Institute of Technology Course on,), 224
Copp, D. J. B. : Reorganization of Microbiological Research in Britain, 416
Copper : Catalytic Action of, in the Alkaline Autoxidation of Cellulose at Low Alkali Concentration (R. I. C. Michie and Dr. S. M. Neale), 534
  The De Haas-Van Alphen Effect in (Dr. D. Shoenberg), 171
  Destruction of Cortisone and related Steroids by Traces of, during Purification Procedures (Marvin L. Lewbart and Vernon R. Mattox), 820
Copper in Fungal Laccase : An Electron Spin Resonance Study of the State of (Dr. Bo G. Malmström, Dr. Rolf Mosbach and Dr. Tore Vänngård), 321

Copper (Divalent) : 5-Co-ordination of (Dr. D. P. Graddon), 1610
Copper Sheet (Rolled) : Nuclear Magnetic Resonance in (E. A. Faulkner), 1043
Copper Uptake (Iodine and), by Soil Organic Matter (J. M. Northmore), 1309
Copper–Cellulose Complexes (Dr. D. S. Belford, C. D. Cook, E. H. Nevard and Prof. R. D. Preston), 988
Copper–Chrome–Arsenate Wood Preservatives : Abnormal Resistance of *Poria vaillantii* (D. C. ex Fr.) Cke. Strains to (E. W. B. Da Costa), 910
Corals irradiated with Ultra-Violet Rays : Fluorescence Effects from (Dr. R. Catala-Stucki), 949
Corals and Marine Plants : Chlorophyll *a* in some (Dr. Paul R. Burkholder, Lillian M. Burkholder and Juan A. Rivero), 1338
Corby, G. A. : Automatic Reduction of Geophysical Data (Preliminary Tests on the Preparation of Numerical Forecasts with the aid of a Computer), 1167
Corday—Morgan Medal and Prize for 1957 awarded by the Chemical Society to Prof. G. W. Kenner, 792
Core (Earth's) : Fusion Curve of Iron to 96,000 Atmospheres—Temperature of the (Dr. H. M. Strong), 1381
Coregonids : Gas Secretion in (Dr. S. Sundnes), 986
Coriaria : Records of Nodulation in (R. E. R. Grimmett), 223
Corixidae (Hemiptera-Heteroptera) : Respiration of (Dr. Edward J. Popham), 914
'Corkscrew-sperms' associated with Sterility in Bulls : A Rare Sperm Abnormality—(Dr. Erik Blom), 1280
Corlett, W. J. : Title of reader in political economy in the University of London (at University College) conferred on, 368
Corn Plant: An Antifungal Substance in the, and its Effect on Growth of Two Stalk-rotting Fungi (N. J. Whitney and C. G. Mortimore), 341
Cornell University : Annual Summer Laboratory Course in Techniques and Applications of the Electron Microscope, 1094
Corner, Dr. E. J. H. : Vegetation of the Humid Tropics, 795
Cornish, E. H., and Cutting, D. M. : A Dose Test for Irradiated Polyethylene, 1804
Cornish, Dr. F. H. J. : Appointed lecturer in applied mathematics at the University of Leeds, 1024
Cornwall, Dr. I. W. : Soils for the Archaeologist, *review* by Dr. Alex Muir, 1355
Corona (Solar) : A New Theory of the (Prof. Paul J. Kellogg and Prof. Edward P. Ney), 1297
    Radio Reflexions from the Moon and (Prof. O. Burkard), 1180
Coronary Arteries and Circulus Willisii of Atherosclerotic Individuals : Composition of Lipids isolated from the Aorta, (Prof. C. J. F. Böttcher, F. P. Woodford, C. Ch. Ter Haar Romeny, E. Boelsma and C. M. Van Gent), 47
Coroniti, S. C., and others : Geophysical Effects of High-Altitude Nuclear Explosions, 1476
Corpuscular Radiation and the Acceleration of Artificial Satellites (Dr. Luigi G. Jacchia), 1662
Corpuscular Radiation (Low-Energy), at High Latitudes (K. D. Cole), 738
Correlation with Iodine-131 in Milk : Increase in Background Gamma-Radiation and its (Measurements at Leeds following the Windscale Reactor Accident), (Prof. F. W. Spiers), 517
Correlation between Iodine Permeability and the Gram Characteristic of Cells (Prof. J. W. Bartholomew, Thomas Cromwell and Harold Finkelstein), 123
Correlation of Sedimentation-Rates by Dimensionless Groups (Colin Harris), 530
Correlation (Genetic), between Two Traits in the House Mouse (*Mus musculus*) : Selection for Relationships Opposite to those predicted by the (F. Cockrem), 342
Correlations (Growth) : Gibberellic Acid and (Prof. R. Dostál), 1338
Correspondence of Sir Joseph Banks, *review* by Dr. W. B. Turrill, 1353
Corrosion, International Congress on : Proposal that it be held in London in 1961, 1094
Corrosion Engineers, British Association of : Formation of, 1779
Cortex (Cerebral) : Electron Microscopy of Synaptic Contacts on Dendrite Spines of the (Dr. E. G. Gray), 1592
    Recurrent Inhibition in (Dr. Roger M. Morrell), 979
Cortex (The Excitable), in Conscious Man (Dr. Wilder Penfield), *review* by Dr. P. B. Bradley, 781
Cortical (Adrenal) Function in the Pregnant Sheep (Kathleen W. Robinson), 690
Corticotropins : Patterns in the Amino-Acid Sequences of the (Drew Schwartz), 464
Cortisone : Effect of Amniotic Fluid on Inhibition of Growth by, in Chicken Embryos (Dr. P. de Franciscis and Prof. W. Landauer), 617
Cortisone and related Steroids : Destruction of, by Traces of Copper during Purification Procedures (Marvin L. Lewbart and Vernon R. Mattox), 820
Cosmetic Chemists : International Federation of Societies of (Formation of an), 1366
Cosmetic Chemists, Society of : British Congress of Cosmetic Science, 934
Cosmetic Science : British Congress of (Society of Cosmetic Chemists), 934
Cosmic Dust in the Atmosphere (Dr. D. W. Parkin and W. Hunter), 732
Cosmic Radiation and the Weather (Prof. Edward P. Ney), 451
Cosmic-Ray Equator and the Geomagnetic Dip Equator : Difference between (Takashi Oguchi and Masahiro Kodama), 103
Cosmic-Ray Exposure Ages of Meteorites : Calculation of Erosion in Space from the (Dr. F. L. Whipple and Dr. E. L. Fireman), 1315
Cosmic-Ray Intensity : Storm-Time Increase of (Prof. Sekiko Yoshida and Masami Wada), 381
Cosmic-Ray Showers, *review* by Dr. R. M. Tennent, 1555
Cosmogenic Noble Gases in the Washington County Meteorite (Oliver A. Schaeffer and David E. Fisher), 660
Cosmology (Dirac's), and the Dating of Meteorites (Prof. R. H. Dicke), 170
Cossins, E. A., and Turner, Dr. E. R. : Utilization of Alcohol in Germinating Pea Seedlings, 1599
Cosslett, Dr. V. E. : Microscopy with X-Rays, 1423
Cotinine, an Oxidation Product of Nicotine formed by Rabbit Liver (Howard B. Hucker, James R. Gillette and Bernard B. Brodie), 47
Cotten, J. : Chromosome Number of the Potato Root Eelworm, *Heterodera rostochiensis* Wollenweber, 128
Cotton, F. A., and Holm, R. H. : Co-ordination Chemistry (Physical Properties and Relative Stabilities of the various types of Cobalt (II) Complex in Solution), 1784
Cotton, Jack : Gift of £100,000 to the Royal College of Surgeons, to establish a chair of biochemistry, 579
Cotton Industry War Memorial Trust Scholarship (Textile Institute), 933
Cottrell, Prof. A. H. : Nuclear Reactor Metallurgy, *review*, 1628
Cottrell, Prof. A. H. (Barnes, R. S., and) : Interfacial Phenomena (Annealing of Radiation Damage in Copper produced by Bombardment with α-particles), 1099
Cottrell, Dr. T. L. : Appointed to the chair of chemistry in the University of Edinburgh, 151 ; work of, 151
    Relaxation Processes (Measurements of Ultrasonics in Gases), 584
Cotzias, Dr. George C., and Greenough, Dr. James J. : Quantitative Estimation of Amineoxidase, 1732
Coulometric Titration Method (An Automatically Operating), for continually Measuring Small Amounts of Water in Fluids (E. Barendrecht), 1181
Coulson, Prof. J. M. : Fluid Systems in Chemical Engineering, *review*, 492
Coumarin : Effect of, on the Germination and Growth of Rice Seedlings (Dr. G. Misra and S. N. Patnaik), 989
Council for Europe : Competition for a thesis on Consequences of the Use of Nuclear Energy for the European Mode of Life, 509
Council for Science and Technology of Western Germany (Dr. J. Horne), 512
Counsell, J. F. : Awarded a Ciba Fellowship for 1959-1960, 1161
Counter, E. R. (Sutcliffe, Dr. J. F., and) : Absorption of Alkali Cations by Plant Tissue Cultures, 1513
Countercurrent (Pacific Equatorial) : Measurements of the (John A. Knauss and Robert Pepin), 380
Countries (Under-developed) : Educational Advancement and the, 633
    National Food Reserve Policies in (United Nations Food and Agriculture Organization, FAO Commodity Policy Studies No. 11), 635
Countryside in Britain : Preservation of the, 917
Coupling (Energetic), in the Respiratory Chain (Dr. Poul E. Glahn and Dr. Sigurd O. Nielsen), 1578
Course on the Control and Instrumentation of Reactors (Harwell Reactor School), 153
Course in Polarography (British Polarographic Research Society), 18
Course for Senior Technical Executives in Industry at the Harwell Reactor School (Atomic Energy Research Establishment), 224
Course on Stereospecific Polymers and Block and Graft Co-polymers (Bradford Institute of Technology), 224
Course (Annual Summer Laboratory), in Techniques and Applications of the Electron Microscope (Cornell University), 1094
Course (Postgraduate), in Biochemical Engineering (University College, London), 933
Course (Postgraduate Lecture), on Recent Advances in Protein Chemistry (Department of Chemistry, Biology and Geology of the Kingston Technical College), 86
Courses at the Harwell Reactor School, 153, 224, 1643
Courses in Statistics and Computational Methods : Scholarships in Mathematics for (London School of Economics and Political Science), 85
Courses (College Biology), on Television, 649
Courses (International), on Nuclear Energy (European Nuclear Energy Agency of the Organization for European Economic Co-operation), 1163
Courses (Summer), of the International School of Physics of the Societá Italiana di Fisica, 1368
Courses (Training) : Grants for (United States Atomic Energy Commission), 437
Courses (Training), at the Shippingport Atomic Power Station (United States Atomic Energy Commission), 153
Courtauld, Augustine : *Obituary* by Prof. L. R. Wager, 930
Courts, Dr. A., and Stainsby, Dr. G. : At the sixteenth meeting of the Research Panel of the British Gelatine and Glue Research Association (Solubilized Collagen), 440
Coussmaker, C. R. C., and collaborators : Co-ordination Chemistry (Properties of the Versatile Complexes of Nickel (II) with Substituted Phosphines), 1784
Coutts, H. H., and others : Drift of Toxic Chemicals released from a Low-flying Aircraft, 131
Cover on River Bottoms (Dr. D. Scott and Dr. J. M. Rushforth), 836
Cowling, Prof. T. G. : Magnetic Field of the Earth, 937
Cows with Hypocupraemia : Iron Content in the Serum of (Dr. Rajmund Rys), 1596
Cox, A. P., and others : Molecular Symmetry in *Cyclo*pentadienyl Thallium and some related Substances from their Microwave Spectra, 1182
Cox, C. B. : Awarded a Harkness Fellowship for 1959 of the Commonwealth Fund, 1093
Cox, Dr. D. R. : Planning of Experiments, *review* by Dr. D. J. Finney, 1766
Cox, Dr. Edward H. : Appointed deputy Science Officer in the American Embassy in Paris, 15
Cox, H. L. : Awarded the George Taylor (of Australia) Gold Medal of the Royal Aeronautical Society, 1648
Cox, Dr. R. N. : Hypersonic Flow (General Characteristics of Hypersonic Flow Fields), 1095
Cox, S. F., and others : Metal-Chelating Properties of Plant-Growth Substances, 1176
Crab-paralysing Agent of the Posterior Salivary Glands of Cephalopods : Cephalotoxin, the (Dr. F. Ghiretti), 1192
Crabs (Shore), *Carcinus maenas* Pennant (Sacculinized) : Behaviour of (Erik Rasmussen), 479
Crabtree, Dr. L. F. : Hypersonic Flow (Hypersonic Boundary Layers with special reference to Aerodynamic Heating), 1095
Crabtree Effect with Ehrlich Ascites Carcinoma Cells : Energy Compensation in the (K. H. Ibsen, E. L. Coe and Dr. R. W. McKee), 1471
Crafts, A. S. (edited by, in association with Machlis, Leonard, and Torrey, John G.) : Annual Review of Plant Physiology, Vol. 9, *review* by Prof. W. Stiles, 1703
Craggs, Prof. J. D. : Gas Discharges (Effect of Electrons on the Broadening of the Balmer Lines), 92
Craik (Kenneth) Research Award : Election to the (St. John's College, Cambridge), 18
Cramer, Robert : Zone Electrophoresis of Rous Sarcoma Virus, 195
Crampton, C. B. : Heavy Minerals in certain Old Red Sandstone and Silurian Limestones of Monmouth, 485

Crane, Dr. E. J. : At the International Conference on Scientific Information (The Importance of Indexing), 148
Cranes (Crowned), in Cambridgeshire (Simon B. Jones and Philip E. H. Jones), 560
Cranston, Dr. Hoy A., and Eggert, Frederick O. : Homologous Species Neoplastic Antibodies, 1471
Crary, Albert P. : Appointed chief scientist of the United States Antarctic Research Programme, 1090 ; work of, 1090
Craters on the Moon, 864
Craters (Lunar) : Simulation of—a Blow-hole Theory (Dr. A. G. Gaydon and R. C. M. Learner), 37
Craters (Lunar), and Maria : Origin of the (Prof. Zdenek Kopal), 169, 737 ; (Dr. William G. van Dorn), 737
Craven, Dr. B., and Jeffrey, Prof. G. A. : Structure of Malvalic Acid and some related C_{18} and C_{19} *Cyclo*propane Fatty Acids, 676
Crawford, Dr. J. D., and Kennedy, Dr. G. C. : Chlorothiazid in Diabetes Insipidus, 891, 1368
Crawley, W. E., and Dodd, D. C. : A Bacterium with Fungicidal Activity, 63
Creating Chromosomal Aberrations : A New Physical Method of (Dr. John H. Heller and Dr. A. A. Teixeira-Pinto), 905
Creation of the College of Technologists, 1500
Cremer, Herbert W., and Davies, Trefor (edited by) : Chemical Engineering Practice, Vol. 5, Fluid Systems I, *review* by Prof. J. M. Coulson, 492
Creole Foundation : Prize for a work on any aspect of Venezuela in the fields of Natural, Physical or Social Sciences, 368
Cretaceous Basalts of Madagascar : Remanent Magnetism of the (Dr. A. Roche and L. Cattala), 1049
Creyssel, Dr. R. (Fine, Dr. J. M., and) : Starch Gel Electrophoresis Studies on Abnormal Proteins in Myeloma and Macroglobulinaemia, 392
Crick, Dr. F. H. C. : Elected a Fellow of the Royal Society, 860
Criterion derived from the Distortion Spectrum : Unpleasantness of Distorted Sounds—a (E. R. Wigan), 1320
Critical Test of Antigenic Relationships (Dr. J. G. Feinberg and Hazel Grayson), 987
Critique of Wittgenstein's Philosophy, *review* by F. I. G. Rawlins, 494
Croatto, Prof. U. (Bruno, M., and) : Structural Chemistry of Promethium, 601
Croft, Dr. A. J. : Hydrogen Liquefaction and Associated Techniques (The Question of Safety), 1505
Crofton, H. D., and Yonge, P. G. : Parasitology (Control of *Diphyllobothrium* Infections in Trout), 1507
Cromartie, Dr. R. I. T. : Naturally Occurring Quinones, *review*, 1291
Crombie, Dr. W. Mary, and Ballance, P. E. : Synthesis of Long-Chain Fatty Acids from 2-^{14}C-Acetate and ^{14}C-Glucose in *Trichoderma viride*, 1195
Cromwell, Thomas, and others : A Correlation between Iodine Permeability and the Gram Characteristic of Cells, 123
Crook, E. M. (organized and edited by) : Biochemical Society Symposium on Metals and Enzyme Activity (Leeds, 1956), *review* by Dr. O. T. G. Jones, 968
Crosfill, M. L., and others : Variation of Sensitivity to Ionizing Radiation with Age, 1729
Crossland, Dr. B. : Appointed to the chair of mechanical engineering at the Queen's University, Belfast, 1779 ; work of, 1779
Cross-linked Polystyrene : Immunochemically Active (L. H. Kent and J. H. R. Slade), 325
Cross-linking by Formaldehyde : Effect of, on the Contraction–Relaxation of Rat Tail Tendon (Dr. H. R. Elden), 332
Cross-linking of Rubber Hydrocarbons by High-Energy Radiation : Estimation of Chain Fracture during the (Dr. L. Mullins and Dr. D. T. Turner), 1547
Cross-linking (Radiation-induced), of Polyvinyl Chloride : Enhancement of (Dr. S. H. Pinner), 1108
Crowcroft, Peter, and Ingles, Jean M. : Seasonal Changes in the Brain-case of the Common Shrew (*Sorex araneus* L.), 907
Crown-Gall Tumour-inducing Principle : *In vitro* Synthesis of the (Alan J. Thomas and Richard M. Klein), 113
Crowned Cranes in Cambridgeshire (Simon B. Jones and Philip E. H. Jones), 560
Cruickshank, Helen Gere (edited by) : John and William Bartram's America, *review* by Dr. L. Harrison Matthews, 1006
Cruickshank, Prof. R. : Elected a Fellow of the Royal Society of Edinburgh, 719
Cruise, A. J., and Jeffery, J. W. : Polysaccharide Fibres in Mammalian Connective Tissue, 677
Crumb (Bread) : Moisture Content of Whole Bread and (Y. Pomeranz), 1222
Crumbs (Soil) : Stability of (Dr. W. W. Emerson), 538
Crust (Earth's), in Antarctica : Thickness of the (F. F. Evison, C. E. Ingham and R. H. Orr), 306
Crustacean Eye (Euphausiid) : Electrical Response to Illumination of the (Elizabeth M. Kampa, Brian P. Boden and Bernard C. Abbott), 1820
Crystal (Quartz) : Sintering of (A. C. D. Chaklader and Prof. A. L. Roberts), 1252
Crystal Compounds of Graphite : Metallic Conduction in the (Prof. A. R. Ubbelohde, Dr. L. C. F. Blackman and J. F. Mathews), 454
Crystal Lattices : Spacing Anomaly in Electron Microscope Images of (Dr. H. Hashimoto and Dr. H. Yotsumoto), 1001
Crystal Structure of Calcium Thymidylate (P. Horn, Dr. V. Luzzati and Dr. K. N. Trueblood), 880
Crystal Structure of Foshagite ($Ca_4Si_3O_9(OH)_2$), (Dr. J. A. Gard and Dr. H. F. W. Taylor), 171
Crystal Structure of β-Glycine (Dr. Yoichi Iitaka), 390
Crystal Symmetry of Struvite (Guanite), (J. A. Bland and S. J. Basinski), 1385
Crystalline Fluors (Solid) : Radioassay of Aqueous Solutions mixed with (Dr. Daniel Steinberg), 1253
Crystallization of Gramicidin (P. E. Olesen and L. Szabo), 749
Crystallographic Orientation of Nodules formed by the Grain Boundary Reaction of Aluminium–Zinc Alloys (Dr. Ryoji Watanabe and Dr. Shigeyasu Koda), 1667
Crystals : Synthetic Quartz (Western Electric Company and the Bell Telephone Laboratories), 294
Crystals of Riboflavin making up the Tapetum Lucidum in the Eye of a Lemur (Antoinette Pirie), 985
Crystals (Ammonium Dihydrogen Phosphate) : Effect of Tartar Emetic on the Growth of (Yutaka Kunisaki), 105
Crystals (Finback Whale Myoglobin) : Electron-Microscopic Study of (D. E. Bradley), 941
Crystals (Liquid), of Lipid in Normal and Atheromatous Tissue (G. T. Stewart), 873
Crystals (Pure and Decomposed), of Thallous Azide : Absorption Spectra and Associated Photoconductivity of (B. L. Evans and A. D. Yoffe), 1241
Crystals (Synthetic Quartz) : Use of, as a Support for Specimens in Powder Photographs (Hitosi Hagihara, Shuji Yamashita and Akitsu Takeda), 1666
Csillik, Dr. B. : Submicroscopic Organization of Post-synaptic Membranes, 1684
Ctenophore (Planktonic), *Pleurobrachia globosa* Moser 1903, from the Madras Coast : Metacercaria (Allocreadioidea) in the (Sita Anantaraman), 1407
Cubic Chromium–Iron and Chromium–Manganese Alloys : Low-Temperature Specific Heats of Body-centred (C. T. Wei, C. H. Cheng and Prof. P. A. Beck), 315
Cubic Equation Machine (Soddy's), handed over to the Science Museum, London, 863
Cultivated Sorghums (Nigerian) : A Chemical Basis for the Classification of Glume Colour in (W. R. Stanton, T. B. Miller and D. L. Curtis), 807
Cultivation (*In vitro*), of the Histotrophic Stages of *Haemonchus contortus* and *Ostertagia* spp. (Dr. Paul H. Silverman), 197
Cultivation of Science, Indian Association for the : Annual Report for 1957-58, 1789
Cultural Affairs : International, 1569
Culture : Morphogenetic Response of *Citrus* Ovules to Growth Adjuvants in (N. S. Ranga Swamy), 735
Culture (Continuous) : Lens Cells of the Calf in (Dr. J. van der Veen and C. F. A. Heyen), 1137
Culture (Sterile), of Roots : A Technique for the (Dr. N. S. Cohn and Dr. T. Merz), 412
Culture (Tissue) : Antibody Formation in (Marvin Fishman), 1200
Culture (Tissue), and Liver Antigens of Mouse Hepatitis : Complement Fixation with (Dr. Theodore J. Starr and Dr. Morris Pollard), 1690
Culture Cells (Tissue) stained with Acridine Orange : Fluorescence of (U. N. Joshi and Dr. K. S. Korgaonkar), 400
Culture-filtrate of *Vibrio cholerae* : Enterotoxicity of Bacteria-free (Prof. S. N. De), 1533
Cultures : Some South African Stone Age (Dr. R. J. Mason), 377
Cultures of certain Micro-organisms growing in Defined Glucose-containing Media : Detection of Gentiobiose and Sophorose in (A. W. Khan, D. N. Pellegrino and Prof. T. K. Walker), 682
Cultures (Plant Tissue) : Absorption of Alkali Cations by (Dr. J. F. Sutcliffe and E. R. Counter), 1513
Cultures (*Spirogyra pratensis*) : Formation of Purple Pigment in (Dr. Ann Allen and Dr. R. E. Alston), 1064
Cunningham, Sir Graham : Elected to Fellowship of the Imperial College of Science and Technology, 1161
Cunningham, Prof. G. J., and others : Chemical Changes in Human Bronchial Epithelium and their relation to Bronchial Cancer, 1743
Curator, Vol. 1, No. 1 (American Museum of Natural History), 223
Curing Brines (Fish and Meat) : The Microbiology of—Proceedings of the Second International Symposium on Food Microbiology (Cambridge, 1957), (edited by Dr. B. P. Eddy), *review* by Dr. Magnus Pyke, 351
Curious Naturalists (Dr. Niko Tinbergen), *review*, 211
Curnow, R. N. : Awarded a Harkness Fellowship for 1959 of the Commonwealth Fund, 1093
Current (High-Field Conduction), in *n*-Hexane : Electric Strength and (A. M. Sletten), 311
Current (Peru), off the Chilean Coast : Relationship between the Hake Fishery and a Southerly Sub-surface Return Flow below the (Dr. Wilhelm Brandhorst), 1832
Current Developments in the Production of High Vacua (Institute of Physics Symposium on), 368
Currents : Turbidity (Royal Astronomical Society Discussion on), 657
Curry, Dr. A. S. : Identification of Barbiturates, 1052
Curtis, D. L., and others : A Chemical Basis for the Classification of Glume Colour in Nigerian Cultivated Sorghums, 807
Curtis, Dr. D. R., and others : Chemical Excitation of Spinal Neurones, 611
Curtis, H. : *Obituary*, 1778
Curve (A Survival), for Mammalian Cells irradiated *in vivo* (Dr. H. B. Hewitt and C. W. Wilson), 1060
Curzon, Dr. G., and Vallet, L. : Preparation of Caeruloplasmin from the *G2* Fraction of Human Plasma, 751
Cusick, Dr. F. : Experimental Approaches to the Problems of Growth and Form in Plants (Floral Morphogenesis in *Primula bulleyana*), 585
Cuthbertson, Dr. D. P. : Function of the Rumen, 1644
Cutter, Dr. E. G. : Experimental Approaches to the Problems of Growth and Form in Plants (Changes in Leaf Arrangement in Individual Fern Apices), 585
Cutter, Dr. E. G., and others : Use of Radioactive Tracers in Studies of the Shoot Apex, 1580
Cutting, D. M. (Cornish, E. H., and) : A Dose Test for Irradiated Polyethylene, 1804
Cuttings (Clematis): Effect of Boron on the Rooting of (Dr. C. J. Weiser), 559
Cuzin, Dr. J. : Phosphates and Organic Substances in Nitrogen Deficiency, 513
Cyanamid European Research Institute, Inc., Geneva, 720
Cyanamid International Information Service : Technical Papers, 1433
Cyanea capillata (Jelly-fish) : The Amphipod, *Hyperia galba*, an Ectoparasite of the (Prof. Erik Dahl), 1749
Cycles : Nuclear Fuel (Institute of Physics, in collaboration with the British Nuclear Energy Conference Symposium on), 1646
Cyclic Allylic Alcohol : Effect of Alkali Salts on the Steric Course of Hydrogenation of a (M. C. Dart and Prof. H. B. Henbest), 817
Cyclic Alternating-Current Voltammetry with a Platinum Electrode (André L. Juliard), 1040
*Cyclo*Hexadienes (Highly Fluorinated) : Thermal Reactions of (B. Gething, Dr. C. R. Patrick and Prof. J. C. Tatlow, and Dr. R. E. Banks, Dr. A. K. Barbour and A. E. Tipping), 586
*Cyclo*heximide (Actidione) : Reversal of Antibiotic Action of, by Bivalent Metal Ions (M. Blumauerová and J. Stárka), 261

*Cyclo*hexylphosphine : Tetra-co-ordination of Nickel (II)—some Complexes with (Dr. Aldo Turco, Dr. Vladimiro Scatturin and Dr. Giovanni Giacometti), 601
*Cyclo*pentadienyl Thallium : Molecular Symmetry in, and some related Substances from their Microwave Spectra (J. K. Tyler, A. P. Cox and Dr. J. Sheridan), 1182
*Cyclo*propane Fatty Acids (C_{18} and C_{19}) : Structure of Malvalic Acid and some related (Dr. B. Craven and Prof. G. A. Jeffrey), 676
Cyprus : Birds of (Dr. David A. Bannerman and W. Mary Bannerman), *review* by Sir Landsborough Thomson, 967
Cystamine and 5-Hydroxytryptamine in Irradiated Rats : Effect of High Oxygen Pressure on the Protective Action of (H. A. S. van den Brenk and Ruth Moore), 1530
Cyst(e)ine Content : Differences in, between Vegetative Cells and Spores of *Bacillus cereus* and *Bacillus megaterium* (Vladimir Vinter), 998
Cystine : Inhibition of Growth and Respiration of *Ophiobolus graminis* var. *avenae* and *Aspergillus niger* by (Elizabeth M. C. Turner), 1130
'Cystine Disulphoxide' : Structure of (B. J. Sweetman), 744
Cytochemical Methods : General (edited by Prof. J. F. Danielli), Vol. I, *review* by Dr. R. Barer, 1355
Cytology at Dublin, 1716
Cytopathogenic Agent from a Mammary Tumour in a *C3H* Mouse that produces Tumours in Swiss Mice and Hamsters (Dr. E. A. McCulloch, A. F. Howatson, L. Siminovitch, A. A. Axelrad and A. W. Ham), 1535
Cytoplasm (Bacterial) : Effect of Drugs upon Components of (Dr. S. Dagley and J. Sykes), 1608
Cytostatic Agent : 1,6-Di-(2-Bromoethylamino)-1,6-Dideoxy-D-Mannitol Dihydrobromide—a New (L. Vargha and T. Horváth), 394
Czanik, Pál (Tárnok, Iván, and) : Malachite Green-reducing Enzyme in *Mycobacteria*, 549
Czechoslovak Academy of Sciences, and the Purkyne Medical Society : Symposium on Antibiotics, 154
Czechoslovakia : Plant Physiology in (Prof. Walter Stiles), 369

DA COSTA, E. W. B. : Abnormal Resistance of *Poria vaillantii* (D. C. ex. Fr.) Cke. Strains to Copper–Chrome–Arsenate Wood Preservatives, 910
Daams, H., and others : Canadian Caesium-Beam Standard of Frequency, 575
Dachille, Frank, and Roy, Prof. Rustum : The Spinel–Olivine Inversion in Mg_2GeO_4, 1257
Dacie, Prof. J. V. : Hemophilia and Hemophilioid Diseases, *review*, 1221
Dagley, Dr. S., and Sykes, J. : Effect of Drugs upon Components of Bacterial Cytoplasm, 1608
Dagley, Dr. S. (Callely, A. G., and) : Biosynthesis of Cell Constituents from C_2-Compounds—Metabolism of Glycine by a Pseudomonad, 1793
Dahl, Prof. Erik : The Amphipod, *Hyperia galba*, an Ectoparasite of the Jelly-fish, *Cyanea capillata*, 1749
Dahlia variabilis Desf. : Leaf-Enations in, induced by Tomato Spotted Wilt Virus (A. A. Brunt), 627
Dahn, Prof. H., and others : Oxidation of Ascorbic Acid and similar Reductones by Nitrous Acid, 163
Dairy Heifers : Effect of Clipping the Coat on the Thermoregulatory Reactions of (H. Berman and H. H. Kibler), 606
Dairy Microbiology (Prof. Edwin M. Foster, Prof. F. Eugene Nelson, Prof. Marvin L. Speck, Prof. Raymond N. Doetsch and Prof. Joseph C. Olson, Jr.), *review* by Dr. C. A. E. Briggs, 637
Dairying, National Institute for Research in : Appointment of Prof. R. G. Baskett as director, 294, 365
Dale, C. H. A. : *A Priori* Probabilities in Gambling, 842
Dale, Sir Henry : Elected an honorary member of the Biochemical Society, 18
Dalhousie University, Halifax : Awarded an annual grant of 90,000 dollars by the National Research Council of Canada, for the establishment of an Institute of Oceanography, 1161
  Appointment of Prof. F. R. Hayes as director of the Institute of Oceanography, 1161
Dallam, R. Duncan, and others : Partition of Selenium-75 in the Intracellular Particulate Matter of Rat Liver, 183
Dalton, John : The Biographical Approach to (Frank Greenaway), *review* by Prof. J. R. Partington, 1765
Dalton, Rodger G. (Fisher, Edward W., and) : Cardiac Output in Cattle, 829
Dalziel, J., and others : Lowest Oxidation States of Technetium and Rhenium, 1755
Dalziel, Dr. J. M. (Hutchinson, Dr. J., and) : Flora of West Tropical Africa, second edition revised by R. W. J. Keay, *review* by A. W. Exell, 6
Damage (Brain) : Oxygen Exposure and (Lars Gyllenstein), 1068
Damage (Chemical Radiation) : Thermal Annealing of (Dr. A. G. Maddock and S. R. Mohanty), 86
Damage (Freezing), to Living Cells : Prevention of, by Dimethyl Sulphoxide (Dr. J. E. Lovelock and Dr. M. W. H. Bishop), 1394
Damage (Hepatic), due to Acute Biliary Obstruction : Determination of Transaminase Activity in Dogs' Serum and Lymph after (Dr. P. Braun, Dr. M. Papp and Dr. I. Horváth), 48
Damage (Myocardial), due to Lymphatic Congestion : Changes in Serum Transaminase Activity following (M. Földi, Dr. P. Braun, Dr. M. Papp and Dr. I. Horváth), 1333
Damage (Radiation), in the Insect *Rhodnius* : Oxygen Deficiency and (W. F. Baldwin and T. N. Salthouse), 974
Damage (Radiation), in Stretched Rubber : X-Ray Diffraction Measurement of (Wesley E. Shelberg and Lewis H. Gevantman), 456
Damage (Spray), in Barley : Varietal Resistance to (J. Desmond Hayes), 551
Dambion, J., and others : Comparative Sensitivity to Radiation of Seeds from a Wild Plant grown on Uraniferous and Non-Uraniferous Soils, 1449
Dameshek, Dr. William (Schwartz, Dr. Robert, and) : Drug-induced Immunological Tolerance, 1682
Dan to Beersheba : From—Excavations in North and South Palestine, *review* by Peter J. Parr, 951
Dancer, Dr. John : Synergistic Effect of Zinc and Gibberellin, 901
Danckwerts, Prof. P. V. : Appointed to the Shell chair of chemical engineering in the University of Cambridge, 719 ; work of, 719
  Appointed to the Board of the College of Technologists, 1500
D'Ancona, Prof. Umberto : Old and New Solutions to the Eel Problem, 1405
Daniel, Dr. Vera : Relaxation Processes (Results of Measurements on a Group of Long-chain Alcohols), 583
Danielli, Prof. J. F. (edited by) : General Cytochemical Methods, Vol. I, *review* by Dr. R. Barer, 1355
Danielli, Prof. J. F. (Coombs, Dr. M. M., and) : Chlorination of Proteins as a Method of Increasing their Opacity in the Electron Microscope, 1257
Daniels, jun., Prof. F., and others : Ultra-violet Carcinogenesis in Albino and Pigmented Mice receiving Furocoumarins—Psoralen and 8-Methoxypsoralen, 728
Danish Atomic Energy Commission (European Nuclear Energy Agency of the Organization for European Economic Co-operation and the) : Symposium on the Scientific and Technical Aspects of Health Physics in Atomic Installations, 934
Dannebrog : Appointment of Prof. J. M. Yoffey as a Knight first class of the Order of the, 154
Daphnia: The Systematics of North American (Dr. John Langdon Brooks), 93
D'Arcy, Dr. P. F., and others : Resolution of Chlorpheniramine and the Pharmacological Properties of its Isomers, 734
Dark : Listening in the—the Acoustic Orientation of Bats and Men (Prof. Donald R. Griffin), *review* by Prof. R. J. Pumphrey, 1554
Dark Fixation of Carbon Dioxide in *Kalanchoe blossfeldiana* in relation to Photoperiodism (Dr. G. Zabka, Prof. F. G. Gregory and Dr. J. Edelman), 1375
Darkness (Old) : New Light on, *review* by Prof. R. J. Pumphrey, 1554
Darlington, Prof. C. D. : Evolution of Genetic Systems, second edition, *review* by Prof. Curt Stern, 1553
Darrieus, G. : Presented with a Gold Medal of the Institut Français des Combustibles et de l'Energie, 151
Dart, M. C., and Henbest, Prof. H. B. : Effect of Alkali Salts on the Steric Course of Hydrogenation of a Cyclic Allylic Alcohol, 817
Dart, Prof. Raymond A. : An 'Australopithecine' Scoop from Herefordshire, 844
Darveniza, M. : Light Emission from Insulating Liquids due to Excitation by d.c. Fields near Breakdown, 743
Darwin, Wallace and Linnaeus Celebrations in Singapore (Prof. R. D. Purchon), 723
Darwin, G. E. : Nuclear Fuel Cycles, 1647
Darwinism and the Study of Society (Scottish Branch of the British Sociological Association Conference to mark the Centenary of 'The Origin of Species'), 1562
Das, T. P., and Hahn, E. L. : Nuclear Quadrupole Resonance Spectroscopy, *review* by Dr. R. H. Tredgold, 1078
Dassualt, Marcel : Awarded the Gold Medal of the Royal Aeronautical Society, 794
Data (Geophysical) : Automatic Reduction of (Royal Astronomical Society Geophysical Discussion on), 1166
Data Processing : Digitizers and other Equipment for (Hilger and Watts, Ltd.), 651
Dating of Meteorites : Dirac's Cosmology and the (Prof. R. H. Dicke), 170
Datta, Dr. S. P., and others : Relationship between Proton and Metal Binding by some Peptides, Amino-acid Amides and Amino-acids, 745
Davey, C. L. : Synthesis of Adenylosuccinic Acid in Preparations of Mammalian Skeletal Muscle, 995
Davey, Dr. K. G. : Serotonin and Change of Colour in Frogs, 1271
David, Dr. W. A. L. : Chemicals and Insects, *review*, 352
Davidson, Prof. C. F. : How Old is the Cambrian System ?, 768
Davidson, Harold (Bukovac, Prof. Martin J., and) : Gibberellin Effects on Photoperiod-controlled Growth of *Weigela*, 59
Davidson, Prof. J. N. : Biochemistry in Medicine, *review*, 5
Davies, B. L., and others : Existence of Two Liquid Phases in the System Cobalt Chloride–Water–Acetone, 459
Davies, Dr. D. D. : Title of reader in plant biochemistry in the University of London (at King's College) conferred on, 86
Davies, D. W. : Mechanization of Thought Processes, 225
Davies, D. W. (Wilkinson, J. H., and) : The Automatic Computing Engine at the National Physical Laboratory, 22
Davies, Dr. E. : Gas Discharges (Influence of Work Function in the Range 2·0–4·5 eV. on the Sparking Potential in Hydrogen at Low Pressures), 92
Davies, Elwyn: Appointed a member of the National Parks Commission, 1094
Davies, Dr. J. G. : Space Research (Terrestrial Radio Astronomy), 363
Davies, Dr. Mansel : Relaxation Processes, 584
Davies, Max, and Verhulst, Michel (edited by) : Operational Research in Practice—Report of a NATO Conference, *review* by Dr. Cecil Gordon, 424
Davies, Robert K., and others : Formation of Urea from Arginine in the Brain of the Living Rat, 1520
Davies, Dr. R. R. : Detachment of Conidia by Cloud Droplets, 1695
Davies, S. F. M. : Parasitology (Possibility that the Onset of Sexual Reproduction of some Parasites is related to Hormonal Changes in the Host), 1506
Davies, Trefor (edited by Cremer, Herbert W., and) : Chemical Engineering Practice, Vol. 5, Fluid Systems I, *review* by Prof. J. M. Coulson, 492
Davis, Dr. D. Russell : Psychiatry in Wartime, *review*, 208
Davis, the late F. M. : An Account of the Fishing Gear of England and Wales, revised edition, 1023
Davis, Dr. G. : Nuclear Fuel Cycles, 1648
Davis, Dr. G. H. G., and Baird-Parker, A. C. : Cell-Wall Composition of *Leptotrichia* spp., 1206
Davis, Dr. J. G. : Elected chairman of the Association of Consulting Scientists, 651
Davis, J. M. : Preparation and Sectioning of Tissues embedded in 'Araldite' for Electron Microscope Examination, 200
Davis, P. S. : Separation of Strontium-90 from Calcium, 674
Davis, Dr. Richard B. (Conn, jun., Dr. Rex B. and) : Green Fluorescence of Guanidinium Compounds with Ninhydrin, 1053
Davison, Dr. A. N., and Wajda, Martha : Persistence of Cholesterol-4-^{14}C in the Central Nervous System, 1606
Dawbin, W. H. : Evidence on Growth-rates obtained from Two Marked Humpback Whales, 1749
Dawes, Dr. Ben : Classification of the Digenetic Trematodes, *review*, 957
Dawes, Dr. Ben, and Griffiths, Dr. Ivor : Relationship between *Dictyocotyle* and *Calicotyle*, 835

Dawkins, M. J. R., and others : Differential Effect of Phenothiazines on Oxidative Phosphorylation, 821
Dawn of Life (Dr. J. H. Rush), *review* by T. H. Hawkins, 966
Dawson, Christine O., and Gentles, J. C. : Perfect Stage of *Keratinomyces ajelloi*, 1345
Dawson, Dr. R. M. C. : Hydrolysis of Lecithin and Lysolecithin by Rumen Micro-organisms of the Sheep, 1822
Dawson, Warren R. (edited by) : The Banks Letters—a Calendar of the Manuscript Correspondence of Sir Joseph Banks preserved in the British Museum, the British Museum (Natural History), and other collections in Great Britain, *review* by Dr. W. B. Turrill, 1353
Day, K. B. : Precipitation in Alloys (The Oxide Replica Technique for Studying Precipitation in Aluminium Alloys), 797
Day : Response of Rice to Small Differences in Length of (Dr. J. Dore), 413 ; (Dr. E. Njoku), 1598
Dazai, Michio (Ono, Hideo, and) : Unfermentable Sugars in Barley Mash fermented by the Amylo Process, 1055
De, Prof. S. N. : Enterotoxicity of Bacteria-free Culture-filtrate of *Vibrio cholerae*, 1533
de Almeida Franco, L. T., and others : Haemoglobin *N* in Portuguese Guinea, 193
de Bodo, Prof. R. C., and others : Mechanism of Action of Insulin, 1123
de Franciscis, Dr. P., and Landauer, Prof. W. : Effect of Amniotic Fluid on Inhibition of Growth by Cortisone in Chicken Embryos, 617
De Groodt, Dr. M., and others : Virus-like Particles in Chemically induced Carcinoma of the Uterine Cervix, 694
de Groot, A. P., and Reed, S. A. : Influence of Dietary Cod-Liver Oil and some Fractions of Cod-Liver Oil on Serum Cholesterol-level of Rats, 1191
de Gruchy, Dr. G. C. : Clinical Haematology in Medical Practice, *review* by Dr. R. Biggs, 1151
de Haan, Hugo : Elected a Fellow of the International Academy of Management, 1719
de Haan, Dr. Reysenbach : The Ear under Water (Aspects of Mammalian Hearing under Water), 1788
De Haas–Van Alphen Effect in Copper (Dr. D. Shoenberg), 171
de Paor, Máire and Liam : Early Christian Ireland, *review* by Joseph Raftery, 1704
de Pietri-Tonelli, P. (Santi, R., and) : Mode of Action and Biological Porperties of the S-(Methylcarbamyl) Methyl 0,0-Dimethyl-Dithiophosphate, 398
De Rom, Prof. F., and others : Virus-like Particles in Chemically induced Carcinoma of the Uterine Cervix, 694
de Rosayro, R. A. : Humid Tropics Vegetation (Aerial Photography applied to Forestry Problems in Ceylon), 795
De Rothschild (James A.) Expedition at Hazor : Hazor I, an Account of the First Season of Excavations, 1955 (Yigael Yadin, Yohanan Aharoni, Ruth Amiran, Trude Dothan, Immanuel Dunayevsky and Jean Perrot), *review* by Peter J. Parr, 951
de Silva, Dr. A. R. : Wheat Genetics, 26
de Vilmorin, Dr. R. : Wheat Genetics, 26
de Vries, J. A., and others : Ethylenediamine Tetraacetate and the Intestinal Absorption of Vitamin B_{12}, 1395
de Winton, John C. P. : Appointed a member of the National Parks Commission, 1094
de la Mare, Dr. P. B. D. : Theoretical Principles of Organic Chemistry, *review*, 852
Deacon, Dr. G. E. R. : Turbidity Currents, 657
Dean, Dr. A. C. R. : Bacterial Population Studies in the Chemostat, *review*, 424
Dearnley, R. (von Knorring, Dr. O., and) : Niobium–Zirconium–Thorium–Uranium and Rare-Earth Minerals from the Pegmatites of South Harris, Outer Hebrides, 255
Death in the Bronze Age : Life and (Sir Cyril Fox), *review* by M. C. Burkitt, 1486
Debt to the Future : Our—Symposium presented on the Seventy-fifth Anniversary, 1957 (Royal Society of Canada 'Studia Varia' Series, Vol. 2, edited by E. G. D. Murray), *review* by R. Brightman, 1702
Decade (Fourth) : Quantum Mechanics in its, *review* by Prof. N. Kemmer, 705
Decay of Intensity of Luminescence of Short-Persistence Phosphors : Rise and (Dr. R. Feinberg), 1546
Decay (Passive Antibody), in Thyroidectomized Rabbits (Dr. Ignatius L. Trapani, Dr. Allen Lein and Dr. Dan H. Campbell), 982
Decay Kinetics of the Metastable State of Chlorophyll *b* : Absorption Spectrum and (Prof. Stig Claesson, Lars Lindqvist and Bertil Holmström), 661
Deciduous Woody Plants : Effect of Gibberellic Acid on Development of Autumn Colour and Leaf-fall of (Dr. P. W. Brian, J. H. P. Petty and P. T. Richmond), 58
Decomposed Crystals (Pure and), of Thallous Azide : Absorption Spectra and Associated Photoconductivity of (B. L. Evans and A. D. Yoffe), 1241
Decomposition of Anionic Surface-Active Agents by Soil Bacteria (Dr. F. A. Skinner), 548
Decomposition of Nitrous Oxide : Effect of Thermal Neutron Irradiation on Oxide Catalysts for the (Yasukazu Saito, Yukio Yoneda and Shoji Makishima), 388
Decomposition Processes (Simultaneous), in Soils (H. F. Birch), 1415
Decomposition (Thermal), of Irradiated Solids (Dr. E. G. Prout), 884
Dedrick (Berry and) : Reactivation of Heat-inactivated Pox viruses—a General Phenomenon which includes the Fibroma–Myxoma Virus Transformation of (Prof. Frank Fenner, I. H. Holmes, Dr. W. K. Joklik and Gwendolyn M. Woodroofe), 1340
Deduction of Ionospheric Electron Content from the Faraday Fading of Signals from Artificial Earth Satellites (W. T. Blackband, B. Burgess, I. L. Jones and G. J. Lawson), 1172
Dee (Aberdeenshire) : *Vibrio* spp. in Finnock from the (Isabel W. Smith), 1409
Defalco, Alfred, and others : Formation of Urea from Arginine in the Brain of the Living Rat, 1520
Defect (Erythrocytic), associated with Drug-Sensitivity among Oriental Subjects : Incidence of the (Dr. Ernest Beutler, Mary K. Y. Yeh and Thomas Necheles), 684
Defence : Central Organisation for (White Paper on), 1483
Defence, Ministry of : Promotion of R. V. Whelpton to Deputy Chief Scientific Officer and appointment as Ministry of Supply representative on the Defence Research Policy Staff, 647
Defence Plan : Progress of the Five-Year (White Paper on), 1483
Defence Research Policy Staff : Promotion of R. V. Whelpton to Deputy Chief Scientific Officer and appointment as Ministry of Supply representative on the, 647
Defence Science, Commonwealth Advisory Committee on—Meeting in Australia (Sir Leslie Martin), 1165
Defence Standards Laboratories, Australian : Annual Report for 1956, 581
Defence Statistics 1950-60 (White Paper on), 1483
Deficiency of Pantothenic Acid : Effects of, on Oxygen Poisoning in the Rat (Dr. D. W. Taylor), 257
Deficiency (Acute Insulin) : Production of, by Administration of Insulin Antiserum (P. H. Wright), 829
Deficiency (Erythrocyte), of Glucose-6-phosphate Dehydrogenase : Gene Action in—Tissue Enzyme-Levels (Prof. Paul A. Marks, Dr. Ruth T. Gross and Dr. Ruth E. Hurwitz), 1266
Deficiency (Nitrogen) : Phosphates and Organic Substances in (International Association for Research on Phosphates Congress on), 513
Deficiency (Oxygen), and Radiation Damage in the Insect *Rhodnius* (W. F. Baldwin and T. N. Salthouse), 974
Deficiency (A Possible Vitamin E), occurring in a Herd of Pigs fed Standard Rations in the Tropics (W. J. A. Payne), 828
Defined Glucose-containing Media : Detection of Gentiobiose and Sophorose in Cultures of certain Micro-organisms growing in (A. W. Khan, D. N. Pelligrino and Prof. T. K. Walker), 682
Degeneration (Dietary Necrotic Liver) : Ineffectiveness of Molybdenum, Osmium and Cobalt in (Dr. Klaus Schwarz, Edward E. Roginski and Calvin M. Foltz), 472
Degenhardt and Co. Ltd. : Exhibition of German Precision Measuring Equipment, 1163
  Exhibition of Photometric Instruments and Microscopes, 1164
Degradation of High Polymers by Gas Chromatography : Direct Examination of the (Dr. R. S. Lehrle and Prof. J. C. Robb), 1671
Degraded Ribonucleic Acid : Inhibition of Polynucleotide Phosphorylation by—its Reversal by various Agents (Dr. Roland F. Beers, jun.), 1335
Dehydrogenase : A Microsomal Malic (Kenneth H. Shull), 259
Dehydrogenase (Glucose-6-phosphate) : Gene Action in Erythrocyte Deficiency of—Tissue Enzyme-Levels (Prof. Paul A. Marks, Dr. Ruth T. Gross and Dr. Ruth E. Hurwitz), 1266
Dehydrogenase (α-Glycerophosphate) : Anion Inhibition of (Dr. Otto Z. Sellinger and Dr. O. Neal Miller), 889
Dehydrogenase (Liver Xanthine), of Rats : Effect of Salicylate on Blood and (Emilio Mitideri and Ottilia R. Affonso), 471
Dehydrogenase Activity (Succinic), in Brain Tissue of Rats after Ovariectomy and Steroid Administration (H. Sobel and B. Eckstein), 54
Dekker, Prof. Adrianus J. : Solid State Physics, *review* by Prof. G. F. J. Garlick, 1007
Delayed Denervation and Accessory Limb Formation in Urodeles (Dr. Laurens N. Ruben), 765
Delaying Pupation in *Drosophila melanogaster* : A New Method for (Dr. A. Abd-el-Wahab), 127
Delinquency : Association between Psychomotor Behaviour and (H. S. Anthony), 343
Delta (Catskill) : *Spirifer disjunctus*, its Evolution and Paleoecology in the (Hugo Greiner), *review* by Dr. H. M. Muir-Wood, 959
δ-Tocopherols (Pure α-, β-, γ- and), in the Growing Chick : Relative Rates of Liver Storage of (T. W. Griffiths), 1061
Demarteau-Ginsburgh, Dr. H., and others : Structure of Phthiocerol, 1117
Demerec, Dr. M. (Miyake, T., and) : *Salmonella–Escherichia* Hybrids, 1586
Demonstration of Endogenous Pyrogen in Serum during Systemic Tuberculin Reaction in Rabbits (Dr. J. Johanovsky), 693
Demonstration of Small Components in Red Cell Haemolysates by Starch-gel Electrophoresis (Dr. Phaedon Fessas and N. Mastrokalos), 1261
Demonstration (Histochemical), of A and B Antigens in Platelets (Dr. B. D. Jankovič and K. Arsenijevič), 695
Demonstration (Histochemical), of Lipase and Alkaline Phosphatase Activity in the Fat Body of the Desert Locust (J. C. George and J. Eapen), 268
Dempsey, Mary, and Green, G. H. : An Abnormality in the Skin of Sheep, 909
Denbigh, Prof. Kenneth G. (Beveridge, Gordon S. G., and) : High-Temperature Oxidation of Zinc Sulphide, 106
Dendrite Spines of the Cerebral Cortex : Electron Microscopy of Synaptic Contacts on (Dr. E. G. Gray), 1592
Denervation (Delayed), and Accessory Limb Formation in Urodeles (Dr. Laurens N. Ruben), 765
Dénes, Dr. G., and Polgár, L. : *T2* Phage Infection of 'Protoplasts' obtained by Penicillin Treatment of *Escherichia coli B*, 696
Denes, P. : The Mechanization of Thought Processes (Speech Recognition), 226
Dennis, Dr. S. C. R. : Appointed lecturer in engineering mathematics at Queen's University, Belfast, 1024
Dennis, S. M. : Isolation of a Lipopoly-saccharide from *Vibrio fetus*, 186
Dennison, A. : Automatic Reduction of Geophysical Data (Echo Method for the Exploration of Underground Geological Formations), 1167
Denotation : Truth and—a Study in Semantical Theory (Prof. R. M. Martin), *review* by F. I. G. Rawlins, 1628
Density of the Atmosphere at Heights between 200 km. and 400 km., from Analysis of Artificial Satellite Orbits (D. G. King-Hele), 1224
Density of Deoxyribonucleic Acids : Dependence of the, on Guanine–Cytosine Content (Heterogeneity in Deoxyribonucleic Acids, 2), (Dr. Noboru Sueoka, Dr. Julius Marmur and Prof. Paul Doty), 1429
Density of the Upper Atmosphere (Dr. George Grimminger), 811
  Irregularities in the—Results from Satellites (D. G. King-Hele and D. M. C. Walker), 527
Density of Water Sorbed on Montmorillonite (Dr. W. F. Bradley), 1614 ; (Dr. Robert C. Mackenzie), 1615
Density (Cohesive Energy), of Polystyrene (Dr. J. H. S. Green), 818
Density (Larval Population) : Influence of, on Fluctuation in Mosquito Numbers (Gordon Surtees), 269
Density-Dependent Factors in Ecology (Dr. H. G. Andrewartha), 200 ; (Prof. G. C. Varley), 911 ; (A. J. Nicholson), 911
Dentice di Accadia, F., and others : Penicillin Derivatives of *p*-Aminobenzylpenicillin, 180, *erratum*, 224

Denton, W. H. (Shaw, Dr. B., and) : Hydrogen Liquefaction and Associated Techniques (Storing Liquid Hydrogen), 1505
Denudation and Burial of Archaeological Structures (Formation by Section H of the British Association for the Advancement of Science of a special Committee to investigate the), 1233
2-Deoxy-D-glucose (Glucose Antimetabolite) : Inhibition of Influenza Virus Multiplication with a (Prof. Edwin D. Kilbourne), 271
Deoxyribonucleic Acid : Content of, of the Germinal Vesicle of the Primary Oocyte in the Rabbit (D. Van de Kerckhove), 329
  Distribution of Newly Synthesized, in Dividing Chromosomes (Philip S. Woods and Marie U. Schairer), 303
  Synthesis of, by Phage-infected *Escherichia coli* in the Presence of Mitomycin C (Dr. Matsuo Sekiguchi and Dr. Yasuyuki Takagi), 1134
Deoxyribonucleic Acid in *Bacillus cereus* growing synchronously out of Spores : Pattern of Synthesis of (Dr. I. Elizabeth Young and Prof. Philip C. Fitz-James), 372
Deoxyribonucleic Acid in *Esherichia coli* : Selective Inhibition of Formation of, by Mitomycin C (S. Shiba, A. Terawaki, T. Taguchi and Prof. J. Kawamata), 1056
Deoxyribonucleic Acid of Human Leukaemic Leucocytes : Incorporation of 5-Iodouracil labelled with Iodine-131 into the, following *in vivo* Administration of 5-Iododeoxyuridine labelled with Iodine-131 (Dr. M. L. Eidinoff, L. Cheong, E. Gambetta Gurpide, R. S. Benua and R. R. Ellison), 1686
Deoxyribonucleic Acid in *L*-strain Fibroblasts : Variability of Content of (Rolla B. Hill, jun., Klaus G. Bensch, Stanley Simbonis and Prof. Donald W. King), 1818
Deoxyribonucleic Acid in the Silk Glands of the Spider *Nephila maculata* Fabr., 1763 : Amounts of (Prof. N. B. Inamdar and U. V. Wagh), 1541
Deoxyribonucleic Acid from various Tissues : Differences in Chromatographic Patterns of (Nobuko Kondo and Syozo Osawa), 1602
Deoxyribonucleic Acid Content of the Cell-Nuclei in the Adrenal Medulla after Exposure to Low Temperatures (L. Leeman), 1188
Deoxyribonucleic Acid (Irradiated) : Electron Spin Resonance in (Dr. J. W. Boag and A. Müller), 831
Deoxyribonucleic Acids : Dependence on Composition of the Configurational Stability of (Heterogeneity in Deoxyribonucleic Acids, 1), (Dr. Julius Marmur and Prof. Paul Doty), 1427
  Dependence of the Density of, on Guanine–Cytosine Content (Heterogeneity in Deoxyribonucleic Acids, 2), (Dr. Noboru Sueoka, Dr. Julius Marmur and Prof. Paul Doty), 1429
  Heterogeneity in—1, Dependence on Composition of the Configurational Stability of Deoxyribonucleic Acids (Dr. Julius Marmur and Prof. Paul Doty), 1427 ; 2, Dependence of the Density of Deoxyribonucleic Acids on Guanine–Cytosine Content (Dr. Noboru Sueoka, Dr. Julius Marmur and Prof. Paul Doty), 1429
Deoxyribonucleotides (Pyrimidine) : Effect of, on the Regeneration of Bone-Marrow in Irradiated Mice (Dr. Z. Karpfel, J. Soška and V. Drášsil), 1600
Dependence on Composition of the Configurational Stability of Deoxyribonucleic Acids (Heterogeneity in Deoxyribonucleic Acids, 1), (Dr. Julius Marmur and Prof. Paul Doty), 1427
Dependence of the Density of Deoxyribonucleic Acids on Guanine–Cytosine Content (Heterogeneity in Deoxyribonucleic Acids, 2), (Dr. Noboru Sueoka, Dr. Julius Marmur and Prof. Paul Doty), 1429
Dependence of the Heat Resistance of Bacterial Endospores on their Dipicolinic Acid Content (Brooks D. Church and Harlyn Halvorson), 124
Deposition (Electrolytic), of Beryllium (Dr. I. A. Menzies, D. L. Hill and L. W. Owen), 816
Deposits (Managanese-rich), of the Sea Floor : Biological Origin of (John W. Graham and Susan C. Cooper), 1050
Depression in Percentage of Milk Fat by Parenteral Glucose Infusion and Glycerol Feeding (W. S. Vallance and Prof. G. L. McClymont), 466
Derivatives : Bromination of Nucleic Acids and their (A. S. Jones and D. L. Woodhouse), 1603
Derivatives (Penicillin), of *p*-Aminobenzyl-penicillin (A. Ballio, Prof. E. B. Chain, F. Dentice di Accadia, Dr. G. N. Rolinson and F. R. Batchelor), 180, *erratum*, 224
Derivatives (Polyphenyl), of the Elements of Groups IV*b* and V*b* : Infra-red and the Near Ultra-violet Absorption Spectra of (Dr. C. N. R. Rao, J. Ramachandran, M. S. C. Iah, S. Somasekhara and T. V. Rajakumar), 1475
Derivatives (Reserpine), with Specific Hypotensive or Sedative Activity (S. Garattini, A. Mortari, A. Valsecchi and L. Valzelli), 1273
Derivatographic Investigation of the Anthracite of the Don (M. Weltner), 1254
Desalting and Group Separation : Gel Filtration—a Method for (Dr. Jerker Porath and Dr. Per Flodin), 1657
Desborough, Sharon, and others : Chromosome Maps of *Saccharomyces*, 800
Desert Locust : Function of certain Prothoracic Hair Receptors in the (Hair Receptors in Locusts), (Dr. P. T. Haskell), 1107
  Histochemical Demonstration of Lipase and Alkaline Phosphatase Activity in the Fat Body of the (J. C. George and J. Eapen), 268
Desert (Libyan) Silica-Glass : Origin of (Dr. Alvin J. Cohen), 1548
Design : Missile Engineering, *review*, 210
Design of Magnetic Amplifiers : The Theory and (Dr. E. H. Frost-Smith), *review* by J. G. Henderson, 1627
Design of Office Chairs and Tables : Anatomical, Physiological and Anthropometric Principles in the (Dr. W. F. Floyd and Dr. D. F. Roberts), 1022
Design for Tropical Living (Report of the Symposium on, prepared by the National Building Research Institute of the South African Council for Scientific and Industrial Research), 1022
Design (Plant) : Instrumentation and Computation in Process Development and (Institution of Chemical Engineers, the Society of Instrument Technology and the British Computer Society Joint Symposium on), 652
Desorption of Moisture in Fired Ceramic Materials : Adsorption and (F. Vaughan and A. Dinsdale), 600
Destruction of Cortisone and related Steroids by Traces of Copper during Purification Procedures (Marvin L. Lewbart and Vernon R. Mattox), 820
Destruction (Chemical), of Mature Perithecia of *Mycosphaerella pinodes* (M. V. Carter), 162 ; *erratum*, 438
Desty, D. H., and others : Separation of *m*-Xylene and *p*-Xylene by Gas Chromatography, 107
Desulphovibrio desulphuricans : A Diagnostic Reaction of (Dr. John Postgate), 481
Deszyck, Dr. E. J. (Ting, Dr. S. V., and) : Isolation of *l*-Quinic Acid in Citrus Fruit, 1404
Detachment of Conidia by Cloud Droplets (Dr. R. R. Davies), 1695
Detecting Power (Magnetic), of Iron-cored Search Coils : Improvement in the (D. F. Walker), 173
Detecting Volatile Airborne Droplets (K. R. May), 742
Detecting and Evaluating Optical Radiation : Modern Systems for (International Commission for Optics Symposium on), 1571
Detection of Antigens as Specific Precipitates on Paper Electrophoresis Strips (S. Buttery), 686
Detection of Carriers in Hereditary Galactosaemia (Dr. Herman M. Kalckar), 1266
Detection of Gentiobiose and Sophorose in Cultures of certain Microorganisms growing in Defined Glucose-containing Media (A. W. Khan, D. N. Pellegrino and Prof. T. K. Walker), 682
Detection of Heterozygous Carriers in Glycogen Storage Disease of the Liver (von Gierke's Disease), (Dr. David Yi-Yung Hsia and Eva Gawronska Kot), 1331
Detection of Hydroxyl Groups in Porphyrins and Chlorins (J. Barrett), 1185
Detection of Keto-Acids (Dr. F. Dobinson), 675
Detection of Meprobamate on Paper Chromatograms (H. S. Bedson and T. H. Farmer), 43
Detection of Phosphate Ester Spots on Paper : Ultra-violet Fluorescence of Quinine Sulphate for (Dr. Edward S. Rorem), 1739
Detection of Sialic Acid in various *Escherichia coli* Strains and in other Species of Bacteria (Prof. Guy T. Barry), 117
Detection and Estimation of Benzenoid Compounds by Chromatography (P. Moss and A. J. Thomas), 1611
Detector (Thermal-conductivity), in Gas Chromatography : Effect of the Carrier Gas on the Sensitivity of a (L. J. Schmauch and R. A. Dinerstein), 673 ; (Dr. N. H. Ray), 674
Detectors (Thermal Conductivity), in Gas Chromatography : Effect of the Carrier Gas on the Sensitivity of (Dr. B. A. Scott and Dr. A. G. Williamson), 1322
Detergence : The Mechanism of (Dr. A. S. C. Lawrence), 1491
Detergent Chemistry : Some Alkyl-Aryl Sodium Sulphonates as Standard Substances in (E. Q. Laws and W. Hancock), 1473
Detergents, Textiles and Dyes (Textile Institute, in collaboration with the Branded Textiles Group Conference on), 1236
Determination of Aldosaccharides in Body Fluids : Rapid Specific Method for (Dr. Eric Hultman), 108
Determination of Aspartic and Glutamic Acids : Rapid Quantitative Horizontal Paper Chromatography at an Elevated Temperature—(Henry R. Roberts and Michael G. Kolor), 460
Determination of Chlorine : A Spectrophotometric Method for the (Zd. Spurny), 1390
Determination of Galactosediethylmercaptal and 3,6 Anhydrogalactosediethylmercaptal with the Anthrone and Seliwanoff Reagents (W. Yaphe), 44
Determination of Human Urinary Œstrogens : A Simplified Physicochemical Method for (Dr. Tawfik El-Attar), 1607
Determination of its Lethal Dose : Effect of the Rate of Elimination of Digoxigenin in the Guinea Pig on the (M. Rand and Anne Stafford), 688
Determination of Molecular Weights of Polysaccharides by Over-oxidation with Periodate (F. W. Parrish and Dr. W. J. Whelan), 991
Determination of Nitrogen in Proteins by means of Indanetrione Hydrate (Dr. S. Jacobs), 262
Determination of Transaminase Activity in Dogs' Serum and Lymph after Hepatic Damage due to Acute Biliary Obstruction (Dr. P. Braun, Dr. M. Papp and Dr. I. Horváth), 48
Determination of the Yields of Molecular Hydrogen Peroxide in the Radiolysis of Water labelled with Oxygen-18 (Dr. J. D. Backhurst, Dr. G. R. A. Johnson, Dr. G. Scholes and Prof. J. Weiss), 176
Determination (Amperometric), of Sulphydryl Content of Blood and Tissues (Dr. S. K. Bhattacharya), 1327
Determination (Direct), of Drug Concentrations in Biological Fluids by Polarography (Dr. P. O. Kane), 1674
Determination (Micro), of Calcium (A. B. Gilbert), 888, 1754
Determination (X-Ray Spectrographic), of Strontium (J. T. Campbell and H. I. Shalgosky), 1481
Determining the Concentration of Ammonium Sulphate Solutions : A Rapid Method for (Dr. John A. Whitaker and Dr. Robert Hughes), 603
Determining the Displacement and Velocity of a Piston in a Hypersonic Gun Tunnel : A Microwave Method of (L. Pennelegion), 246
Determining the Duration of Antibody Formation by Transferred Cells : Presence of Antigen—a Factor (Dr. J. Sterzl), 547
Detonation : Suppressed Light Emission of the Reaction Zone in (Prof. C. H. Johansson and L. Sternhoff), 247
Detonation (Advance), in a Tubular Charge of Explosive (Dr. D. W. Woodhead), 1756
Dettbarn, Dr. Wolf D. : Distinction between Sodium and Potassium in Change in Permeability effected by Lipid-Soluble Analogues of Acetylcholine, 465
Deutsch, Dr. J. A., and Clarkson, J. K. : Nature of the Vibrato and the Control Loop in Singing, 167
Deutsch, Dr. J. A., and Jones, A. D. : The Water–Salt Receptor and Preference in the Rat, 1472
Deutsche Akademie der Naturforscher Leopoldina : Election of new Members, 652
Dev, Sukh (Bose, Dr. M. N., and) : Occurrence of Two Characteristic Wealden Ferns in the Jabalpur Series, 130
Development of Autumn Colour and Leaf-fall of Deciduous Woody Plants : Effect of Gibberellic Acid on (Dr. P. W. Brian, J. H. P. Petty and P. T. Richmond), 58
Development in Britain : Scientific Man-power and, 67
Development of Electric Cables (S. E. Goodall), 226 ; (Prof. James Greig), 226
Development in a Mutelid Lamellibranch (Dr. G. Fryer), 1342
Development of Ovarial Teratomas in Viviparous Toothcarps by Pathological Parthenogenesis (Prof. A. Stolk), 763

Development of Resistance against Fluorouracil in Ascites Tumours : Possible Enzymic Mechanism for the (Dr. Peter Reichard and Ola Sköld, and Prof. George Kein), 939
Development of Shoot Buds on the Protonema of (*Pohlia nutans:* Effects of Kinetin, Gibberellic Acid and certain Auxins on the (Dr. G. C. Mitra and Dr. A. Allsopp), 974
Development of the Steel Industry (Political and Economic Planning, Broadsheet No. 428), 222
Development of Tumours : Cell Growth and the (Anna Kane Laird and A. D. Barton), 1655
Development Commissioners, in association with the Ministry of Agriculture, Fisheries and Food, and the Scottish Home Department : Postgraduate Training Grants in Fishery Research, 1094
Development and Genetic Assimilation of Acquired Characters : Canalization of (Prof. C. H. Waddington), 1654
Development and Welfare Bill, Colonial : Second reading of the, 793
Development (Abnormal), of the Basis in *Balanus amphitrite* var. *stutsburi* Darwin (Dr. H. G. Stubbings), 1282
Development (Mycorrhiza), on Fly Ash : Forest Seedlings and (A. Sobotka and J. Materna), 1066
Development (Process), and Plant Design : Instrumentation and Computation in (Institution of Chemical Engineers, the Society of Instrument Technology and the British Computer Society Joint Symposium on), 652
Development (Scientific Research and), in Colleges and Universities—Expenditure and Manpower, 1953-54 (National Science Foundation), 1717
Development (Scientific and Engineering Research and), in British Manufacturing Industry (1955) : Estimates of Resources devoted to (Department of Scientific and Industrial Research), 847
Developmental Cycle in Domestic Groups (edited by Dr. Jack Goody), *review* by Dr. Rodney Needham, 1625
Developments in Adult Education, *review* by T. H. Hawkins, 1419
Developments in Photoelasticity—Commemoration at University College, London (Prof. R. E. D. Bishop), 1495
Developments in Plant Physiology : Recent, *review* by Prof. W. Stiles, 1703
Developments (Current), in the Production of High Vacua (Institute of Physics Symposium on), 368
Devices : Dielectric (Electrical Engineering Department of the University of Birmingham Residential Conference on), 1783
Devil's Repertoire or Nuclear Bombing and the Life of Man (Victor Gollancz), *review* by R. Brightman, 952
Devonian (Upper) Spirifers of the Catskill Delta, *review* by Dr. H. M. Muir-Wood, 959
Dew-Hughes, D., and Robertson, W. D. : Interfacial Phenomena (Mechanism of Hardening in Aluminium–Copper Alloys), 1099
Dewar, Prof. M. J. S. : Chemistry in Schools, *review*, 566
Dewey, D. L., and Boag, Dr. J. W. : Modification of the Oxygen Effect when Bacteria are given Large Pulses of Radiation, 1450
Dexter Award for 1959 of the American Chemical Society awarded to Prof. John Read, 1304
Dextran Sulphate labelled with Carbon-14 : Synthesis of, and Tracer Experiments in the Rat (Dr. H. Weigel and Dr. K. Walton), 981
Dhar, Prof. N. R. : Phosphates and Organic Substances in Nitrogen Deficiency, 513
Obituary of Sir J. C. Ghosh, 645
Di Sabato, Dr. G. : Effect of Reduced Diphosphopyridine Nucleotide on the Swelling of Isolated Mitochondria, 997
Di-*n*-butyl Phosphate : Separation of Mono-*n*-butyl Phosphate and, by means of Ion Exclusion (E. Cerrai and F. Gadda), 1528
Diabetes Insipidus : Chlorothiazid in (Dr. J. D. Crawford and Dr. G. C. Kennedy), 891, 1368
Diagnostic Feature of *T. vavilovi* : An Induced Mutant in *Triticum carthlicum* with the (Z. Barabás, jun.), 1349
Diagnostic Performance Tests (Boris Semeonoff and Eric Trist), *review* by Prof. O. L. Zangwill, 1767
Diagnostic Reaction of *Desulphovibrio desulphuricans* (Dr. John Postgate), 481
Diamant, Herman (Zotterman, Prof. Yngve, and) : Has Water a Specific Taste ?, 191
Diamond, Prof. J. : Nuclear Fuel Cycles, 1648
Diamond : Absolute Measurement of the Intensity of the (111) Reflexion for (Prof. R. Brill and H. Zandy), 1387
Diapause : Control of, by an 'Internal Clock' in *Anthrenus verbasci* (L.) (Col., Dermestidae), (G. M. Blake), 126
Diapause Embryos of *Acheta commodus* W. : A Rapid Method for examining (T. W. Hogan), 269
Diaphragm (Rat) : Influence of Ions on the Uptake of Glucose and on the Effect of Insulin on it by (Dr. Gangagobinda Bhattacharya), 324
Diaphragms of Hypophysectomized Rats : *In vitro* Effects of Insulin and Glucose on Leucine-2-^{14}C Incorporation into Protein of (Dr. J. L. Kostyo), 1518
Diathesis : Hyperglobulinaemic Thrombo-Haemorrhagic (Dr. Henry H. Henstell and Miriam Kligerman), 978
Diatomic Band Spectra : Changes in Transition Probability due to the Interaction of Rotation and Vibration in (R. C. M. Learner and Dr. A. G. Gaydon), 242
Dibromide (β-Aminoethyl*iso*thiouronium) : Anti-Thyroid Action of, in Rats (John Osmer, Dr. Robert B. Jennings and Dr. Robert M. Dowben), 470
2,4-Dichlorophenoxyacetic Acid : Spraying of Barley with (E. L. Leafe), 621
Dick, Prof. J. : *Obituary* of Prof. A. R. Fulton, 505
Dicke, Prof. R. H. : Dirac's Cosmology and the Dating of Meteorites, 170
Dickens, P. G., and others : Use of Approximate Wave Functions for Extrapolation to True Energy Values, 175
Dicobalt Octacarbonyl at Elevated Temperature and Carbon Monoxide Pressure : Behaviour of (Sol Metlin, Irving Wender and Heinz W. Sternberg), 457
Dictionary (Oxford English) : Books required for the, 1434
Dictionary of Physics (compiled and edited by H. J. Gray), *review* by Prof. H. Lipson, 1768
Dictynidae (The Spider Family), in America North of Mexico (Prof. Ralph V. Chamberlin and Willis J. Gertsch), 1170
Dictyocotyle and *Calicotyle :* Relationship between (Dr. J. Llewellyn), 835 ; (Dr. Ben Dawes and Dr. Ivor Griffiths), 835
Diecke, F. P. J., and others : Pattern of Recurrent Conditioning of Spinal Reflexes, 824
Dieldrin in Trinidad : Resistance of *Anopheles aquasalis* Curry to (T. A. Omardeen), 131
Dieldrin Resistance in *Lucilia cuprina* Wied. : Genetics of (G. J. Shanahan), 1540
Dielectric Constant of the Interior of Erythrocytes : Electrical Conductance and (H. Pauly), 333
Dielectric Devices (Electrical Engineering Department of the University of Birmingham Residential Conference on), 1783
Dielectric Properties (Microwave), of Indian Shellac in the 8-mm. Range (Dr. S. S. Srivastava and Dr. D. D. Puri), 37
Diet : A Relationship between some Bacteria, Protozoa and, in Early Weaned Calves (J. Margaret Eadie, Dr. P. N. Hobson and S. O. Mann), 624
Diet (Protein-free) : Effect of, on the Vitamin A Storage in the Rat Liver (M. Rechcigl, jun., S. Berger, J. K. Loosli and H. H. Williams), 1597
Dietary Change in *Harmolita hyalipenne* Walker : Facultative Parasitism and (R. Bailey), 341
Dietary Cod-liver Oil and some Fractions of Cod-liver Oil : Influence of, on Serum Cholesterol-level of Rats (A. P. de Groot and S. A. Reed), 1191
Dietary Necrotic Liver Degeneration : Ineffectiveness of Molybdenum, Osmium and Cobalt in (Dr. Klaus Schwarz, Edward E. Roginski and Calvin M. Foltz), 472
Dietary Phytate : Effect of, on Faecal Absorption of Radioactive Ferric Chloride (Dr. Henry Foy, Athena Kondi and W. H. Austin), 691
Dietary Protein : Effect of, on the Severity of Experimental Mouse Hepatitis (Dr. Boris Ruebner and James L. Bramhall), 609
Diethyl Acetamidomalonate : Asymmetric Hydrolysis of, by Chymotrypsin (Prof. Saul G. Cohen and Lucille Altschul), 1678
Diethyl Sulphate and Labelled Sulphuric Acid : Exchange Reaction induced by Radiation between—a Possibly Ionic Reaction (Dr. Paul Y. Feng and Ahren Jacobson), 251
Diethylamide (Lysergic Acid) : Quantitative Measurement of the Effect of, on Mice and its Interactions with other Drugs (Dr. J. R. Smythies), 545
Difference between Cosmic-Ray Equator and the Geomagnetic Dip Equator (Takashi Oguchi and Masahiro Kodama), 103
Difference (Reciprocal) : Assortative Mating and, in the Blue–Snow Goose Complex (Dr. F. G. Cooch and Dr. J. A. Beardmore), 1833
Difference Equations : Introduction to, with Illustrative Examples from Economics, Psychology and Sociology (Prof. Samuel Goldberg), *review* by Dr. L. S. Goddard, 970
Differences in Chromatographic Patterns of Deoxyribonucleic Acid from various Tissues (Nobuko Kondo and Syozo Osawa), 1602
Differences in Cyst(e)ine Content between Vegetative Cells and Spores of *Bacillus cereus* and *Bacillus megaterium* (Vladimir Vinter), 998
Differences in Mechanism in Staining Reactions for Mast Cells (Dr. Harold M. Fullmer), 1274
Differences between Self-Incompatibility and Self-Sterility (J. S. Bubar), 411
Differences (Small), in Length of Day : Response of Rice to (Dr. E. Njoku), 1598
Different Combinations of Chance and Skill in Gambling : Preferences for (Prof. John Cohen and C. E. M. Hansel), 841
Differential Distribution of Radioactive Strontium and Yttrium in the Tissues of the Rabbit's Eye (R. H. Mole, Antoinette Pirie and Janet M. Vaughan), 802
Differential Effect of Phenothiazines on Oxidative Phosphorylation (J. D. Judah, Dr. K. R. Rees and M. J. R. Dawkins), 821
Differential Equations : Boundary Problems in (Mathematics Research Center, United States Army, Symposium on, at the University of Wisconsin), 224
Differential Fungicidal Effect : 'Karathane'—the value of its, in relation to Mildew and Yellow Rust of Wheat (D. A. Doling and Shirley Hepple), 622
Differential Reaction to Saprophytic and Parasitic Soil-inhabiting Fungi to Indoleacetic Acid (E. W. B. Ward and Prof. A. W. Henry), 1064
Differential Response of Human Serum Cholinesterase Types to an Inhibitor in Potato (Dr. H. Harris and Mary Whittaker), 1808
Differential Response of Male and Female Adults fo *Trogoderma granarium* Everts towards Sterilizing Doses of Gamma-radiation (G. C. Carney), 338
Differentiation (Biochemical), of Group *A* and 'Human *C*' *Streptococci* (R. W. Henningson), 182
Differentiation (Population), within Plant Species in Response to Soil Factors (A. D. Bradshaw and R. W. Snaydon), 129, *erratum*, 368
Differentiation (Strain), in a Root-infecting Fungus (Dr. Ida Levisohn), 1065
Diffraction (Neutron), at a High-Flux Reactor (Dr. G. E. Bacon and R. F. Dyer), 35
Diffraction (X-Ray) : Fourier Transforms and (Prof. H. Lipson and Dr. C. A. Taylor), *review* by Dame Kathleen Lonsdale, 969
Diffraction Lines (X-Ray), in Teeth affected by Fluorine : Broadening of the (Mrs. E. A. Scott and Dr. F. H. Scott), 479
